ATHENS

ATHENS (Ἀθῆναι, ATHENÆ) was the name of as many as nine towns in various parts of the Grecian world, among which *Athenæ Diades*, in the N.W. of Eubœa, a town belonging to the Athenian confederation, is worthy of mention. But it was the capital of Attica which invested the name of Athens with an undying charm for the poet, the artist, the philosopher, the historian, for all time. It is situated in long. 23° 44′ E., lat. 37° 58′ N., towards the south of the central plain (πεδίον) of Attica, about 4½ miles from the harbour of Piræeus, and nearly 4 from the Bay of Phalerum. The survey of Pausanias (i. 2-30), when compared with existing remains, and supplemented by the numerous incidental notices of ancient authors, enables us to form a more perfect conception of the topography of ancient Athens than of any other Greek city. Recent excavations have added greatly to our knowledge of it, and the literature of the subject is very extensive (see p. 11, *infra*). Our object in this article will be to treat of the topography of Athens from an historical point of view, and to show how the rise, the greatness, the decline of the city may be read in the history of its buildings.

'liest :lement the ·opolis.

There seems little reason to doubt that the earliest settlement on Athenian soil was upon the cliff afterwards famous as the Acropolis. Such is the express statement of Thucydides (ii. 15), who observes that the Acropolis was commonly termed at Athens ἡ πόλις, much as the oldest part of London is styled "The City." The earliest inhabitants appear to have been Pelasgians; and though it was the boast of the Athenians that they alone of all Greek states were indigenous (αὐτόχθονες), yet their town would from the first have received accessions from various parts of the continent, the peaceful poverty of Attica affording a welcome refuge in those early and unsettled times (Thucyd., i. 2). The most accessible portion of the Acropolis is the western side, where it is joined by a neck of hill to the Areopagus. On this side there existed down to later times the remains of fortifications built by the earliest inhabitants, with nine doorways, one within the other, called τὸ Πελασγικόν, or τὸ Ἐννεάπυλον. This fort protected the only entrance to the citadel, which was surrounded by a wall, and artificially levelled for the reception of buildings. Within this fortified enclosure stood the shrine of Athena Polias (Homer, *Iliad*, ii. 449; *Odyssey*, vii. 81), afterwards known as the Erechtheium,—and an altar of Zeus Polieus, where the strange sacrifices of the Dipolia were celebrated. A Prytaneium, containing the hearth-fire of the state, and serving as the residence of the king, would be another indispensable feature in the primitive town. But while the king and some of the most sacred families probably had dwellings within the fortress itself, Thucydides (ii. 15) points out that a great part of the early population dwelt outside its walls, under the south side of the cliff, probably without fortification, but retiring to the citadel in times of peril. In this quarter, towards the Ilissus, stood the oldest Athenian sanctuary of Dionysus, in a region called Λίμναι, from having been literally a marsh in early times. Not far off, and nearer the stream, stood the temple of Zeus Olympius, said to be founded by Deucalion (Pausan., i. 18), of which more will be said presently, the precinct of Gæa Olympia, and other sacred places. Here also was the fountain of Callirrhoe, afterwards ornamented by the Pisistratids, and called Enneacrunus, the water of which was sought for sacred purposes long after the city had outgrown these early limits (Thucyd., ii. 15). The region we have been describing formed the nucleus of the later city, and therefore, at the subdivision of all Attica into demes, this quarter was distinguished by the name Κυδαθήναιοι.

To the west of the Acropolis there extends from N. to S. a range of hills, the three most prominent heights of which are commonly known respectively as the Hill of the Nymphs, the Pnyx, and the Museium,—the Nymphs' Hill being separated from the Acropolis by the Areopagus, which intervenes between. Everywhere upon the slopes of the hills just mentioned traces have lately been discovered of ancient dwellings hewn out of the solid rock. But while all these rock-dwellings are extremely ancient, yet some appear less primitive than others; it is remarked that those which exist on the Areopagus and on the hill-sides nearest to the Acropolis are of a smaller and ruder type, those more distant from the citadel being somewhat more convenient in plan and extent. Legend declares the Athenians to have originally dwelt in rock-hewn caves (Dyer's *Athens*, ch. i.), and it would seem that primitive Athens gradually extended itself from the Acropolis in this W. and S.W. direction. This quarter was afterwards

Early rock-dwellings.

known as the intramural deme of Melite, a name derived, perhaps, from the balm which then grew there (the *εὐώδης μελίτεια* of Theocr., iv. 25).[1] The historian E. Curtius (*Attische Studien*, pt. i.) has, indeed, gone so far as to regard these rock-dwellings as earlier than the occupation of the Acropolis itself. But the contrary opinion of Thucydides is worth something, and the natural strength of the Acropolis would make it the most obvious spot for primitive occupation. Accordingly, we shall not be giving too free a licence to our imagination if we conceive of primitive Athens as a twofold settlement, partly on the Acropolis and the low ground at its southern foot, and partly upon the eastern slopes of the hills on the west. It may even have been the consolidation of these two villages into one township that gave rise to the legend ascribing to

Thesean *συνοικισμός*.

Theseus the *συνοικισμός* or consolidation of Attica. It would be natural for legend to assign to one definite time, and connect with one great mythical name, that process of unification which probably was as gradual as it was spontaneous. As the population of the early town continued to increase, two more districts seem to have been incorporated—Collytus, extending from the east of Melite, between the Acropolis and Areopagus, and Cerameicus, or the "Potters' quarter" ("Tuileries"), which extended from the same two hills towards the north and north-west. The regions we have now described appear to have made up the Athens of Solonian times. The earliest historical event which illustrates Athenian topography is the rising of Cylon (Herod., v. 71; Thucyd., i. 126; Pausan., i. 28). The narratives of that event imply that the Acropolis was already fortified by the Enneapylum, that the Areopagus was already the seat of the court which bore its name (see AREOPAGUS), and that near the entrance of the citadel

Altar of the Semnæ.

stood an altar of the Semnæ, or Furies, at which Cylon and his partisans were slain. This altar has been immortalised by Æschylus in the splendid conclusion of the

Leocorium.

Eumenides. Another sacred spot in early Athens must have been the *Leocorium*, where Hipparchus was assassinated (Thucyd., i. 20; vi. 57). This was a shrine erected in honour of the daughters of Leo, who were sacrificed by their father to Athena, in order to avert a pestilence. The nature of the legend testifies to the antiquity of the site. The words of Thucydides respecting Cylon imply

Early city wall.

that the early city was already surrounded by a ring-wall, and this probably remained intact until the invasion of the Persians, although the buildings within the walls underwent great alteration and improvements under the government of Pisistratus and his sons.

The Pisistratids.

The reign of the Pisistratids was recognised by the ancients as marking an important era in Athenian topography. We have already mentioned the fountain of Enneacrunus as being built by them. It was Pisistratus

Olympium.

who laid the foundations of the great temple of Zeus Olympius upon the ancient site above mentioned. His magnificent design had an eventful history; left unfinished by its author, the Athenians, perhaps from dislike to the "tyrant," made no effort to complete it. At length, after receiving additions from various foreign princes, it was completed by Hadrian (c. 130 A.D.), and formed the grandest edifice in the region of the city which, in acknowledgment of the imperial munificence, was called Hadrianopolis. The Olympium was one of the largest temples in the world; but of its 124 Corinthian columns only 15 are

Pythium.

now standing. The *Pythium*, or sanctuary of the Pythian Apollo near the Olympium, was also ascribed to Pisistratus, whose grandson and namesake dedicated an altar within it (Thucyd., vi. 54). To Pisistratus was ascribed

Lyceiu

the founding of the *Lyceium*, or temple of Apollo Lyceius, which stood on the right bank of the Ilissus, a short distance from the city. The names both of Pericles and Lycurgus the orator are also associated with this building; yet it is not known who added the gymnasium close by, which afterwards became famous as the favourite haunt of Aristotle, and the birthplace of the Peripatetic philosophy. The yet more famous seat of the rival philosophy seems also to have owed something to the Pisistratids, for

Academ

Hipparchus was said to have enclosed the *Academy* with a wall. This was a gymnasium surrounded by pleasant gardens lying to the N. of the city, about a mile from the Dipylum gate. It owes all its fame, of course, to its connection with Plato, who lived, taught, and was buried there. This site, so full of glorious memories, cannot now be identified with certainty. Its trees, like those of the Lyceium, were despoiled by Sulla to make implements of

The Agc

war. The name of Pisistratus is connected with another important site. Professor E. Curtius (*Attische Studien*, pt. 2) supposes that the most ancient Athenian market lay on the S. of the Acropolis, and that the Pisistratids superseded it by a new market at the northern foot of the Areopagus. Be this as it may, we are sure that, as early as their times, this site formed the centre of Athenian commercial and civic life. The narrow valley between the Pnyx Hill and the Areopagus, where older topographers placed the Agora, is not a spacious enough site for the purpose. The obvious locality for an Agora would be the rectangular space enclosed by the Areopagus on the S., by the Acropolis on the E., and on the W. by the eminence occupied by the Theseium. To the N. and N.E. no barrier existed; accordingly, the entrance was from the Dipylum gate on the N.W., and on the N.E. the market received extension in Roman times. The Agora thus stood in the region known as Cerameicus. But as the Cerameicus extended for some miles in a N.W. direction, it became

Outer a inner Ce meicus.

divided by the city wall into the outer and the inner Cerameicus. The outer Cerameicus was an agreeable suburb, lying on the road to the Academy and Colonus, the home of Sophocles; and it was here that citizens who died in their country's wars received a public burial. Through gate Dipylum one passed into the inner Cerameicus, the most important quarter of which was naturally the Agora itself; and so it was common to speak of the Agora as "The Cerameicus." How much this market-place may have owed to the designs of the Pisistratids we cannot now determine. The statues of Harmodius and Aristogiton formed a conspicuous ornament of the south portion, and Thucydides (vi. 54) informs us that the grandson and namesake of Pisistratus adorned the Agora by building the altar of the twelve gods. If the Agora belongs to the age of Pisistratus, some of the civic buildings within it would also be coeval with him. Such were the Stoa Basileius, or Portico, where the archon basileius presided; the Bouleuterium, where the senate of 500 held its sittings; the Tholus close by it, where the Prytanes of the senate sacrificed—a circular building with a dome of stone, from whence it gained its name; and the Prytaneium, said to be founded by Theseus (Thucyd., ii. 15), which contained the hearth-fire of the state, and where the Prytanes and public benefactors had the privilege of dining at the public expense. The statues of the ten heroes (eponymi), who gave their names to the Athenian tribes, decorated the Agora probably from the first; against these statues were affixed public notices and proclamations. Other buildings in the Agora of later and ascertained dates will be enumerated in their proper place.

---

[1] Many of the names of the Attic demes, and indeed of Greek local names everywhere, were derived from plants and flowers; see Tozer's *Lectures on the Geography of Greece*, p. 338: "The most plausible derivation that has been suggested for the name Ἀθῆναι is from ἀθ-, the root of ἄνθος, a flower; and Lobeck proposed to translate it by '*Florentia*.'"—(*Ibid.*, p. 161.)

The revolution which expelled the Pisistratids (510 B.C.), and gave Athens a free government, left its mark upon the topography of the city. The old Pelasgic fortress (τὸ Ἐννεάπυλον), in which "the tyrants" had for a time held out, was now broken down, and the site occupied by its ruins was devoted by the Delphic oracle to eternal desolation. Only in the Peloponnesian war, when the country population was crowded within the city walls, do we read of this spot being occupied by dwellings (Thucyd., i. 17). Another work which may probably be assigned to the age of Clisthenes is the first arrangement of the Pnyx, or place of public assembly. The hill that is commonly known as the Pnyx Hill contains one of the most remarkable ruins in Athens; the silence, however, of Pausanius respecting what was probably in his day already a mere ruin has occasioned some doubt concerning its proper identification. The spot in question consists of two terraces sloping down the hill towards the Areopagus, from S.W. to N.E. The upper terrace, indeed, does not slope, but is levelled out of the solid rock near the summit of the hill, being about 65 yards in length (E. to W.), and about 43 in breadth at its broadest part (N. to S.). It is bounded at the back (S.) by a rock-wall, and at the W. end there stands a cubical block, allowed to rise out of the solid rock when this upper terrace was levelled. There is good reason for considering this as the altar for the sacrifices (τὰ περίστια) with which every assembly of the ecclesia was opened (Bursian, *Philologus*, 1854, p. 369, *foll.*; Dyer, *Athens*, p. 462). The lower and considerably larger terrace is separated from the upper terrace by another wall cut out of the solid rock. This wall, which is nearly 126 yards long, is not quite straight, but encroaches slightly upon the upper terrace, and forms at the centre a very obtuse angle. At this point there rises, projecting from the wall, a large cubical mass, cut out of the solid rock, resembling somewhat, though on a larger scale, the altar described above. It is itself 11 feet square and 5 feet high, and stands on a platform consisting of three very massive steps. This remarkable monument has been recognised by tradition as the σκάλα τοῦ Δημοσθένεος, and almost every traveller since Chandler's time has regarded it as no other than the famous bema of the ancient Athenian assembly. The rock-wall from which it projects forms the chord of a vast semicircular space, the enclosure of its arc being a wall of "Cyclopean" masonry. The radius of the semicircle measures between 76 and 77 yards from this outer wall to the bema. Here, then, was the auditorium of the Pnyx. But several difficulties beset the identification. Towards the bottom of the lower bema Prof. E. Curtius (*Attische Studien*, pt. i.) has discovered another similar though smaller bema. Again, Plutarch asserts that the bema which had originally faced towards the sea was by the Thirty Tyrants turned round the other way, in their hatred of the maritime democracy. Moreover, if the block of marble above mentioned be rightly identified as the bema, then it would have the auditorium sloping downwards from it, an arrangement ill suited for addressing a tumultuous popular assembly. Dr Curtius accordingly pronounces the entire identification to be a mistake, and would regard this spot as a primitive precinct and rock-altar of the Most High Zeus. It would not be difficult, if space allowed, to disprove Dr Curtius's theory. Far more reasonable is the view of Dr Dyer (*Athens*, App. iii.). He thinks that the lower and smaller bema discovered by Dr Curtius was the bema of Clisthenes, which did (however much Plutarch's statement is discredited by his own absurd explanation) face in the direction of the sea. The orator would thus speak from the arc of the semicircle, having the audience above him. The Thirty may well have defaced the Pnyx, and it would have been natural for Thrasybulus after the anarchy to restore it on a large scale, hewing out what is still known as the bema, giving the semicircular wall a wider sweep, and raising the tiers of seats at least to a level with the new bema, if not above it. For there is no reason to suppose that the surface of the lower terrace has undergone no change in the lapse of centuries, or that the "Cyclopean" wall surrounding it never exceeded its present height.

The Dionysiac theatre.

A building of greater architectural importance and of equal interest belongs to this same period. Dramatic performances at Athens originally took place in wooden theatres extemporised for the occasion; but the fall of one of these led, in the year 500 B.C., to the erection of the marble theatre on a site already consecrated to Dionysus as the Lenæum, upon the S.E. slope of the Acropolis. (Suidas, *s.v.* Πρατίνας.) We may be sure that the first stone theatre was comparatively simple in construction, consisting of a κοῖλον or auditorium, with tiers of rock-hewn seats, and an ὀρχήστρα, or space for the chorus, while the stage itself and its furniture were of wood. The excavation of the Dionysiac theatre in 1862 has made every one familiar with the row of marble thrones for the various priests and officers of state, the elaborate masonry of the stage, the orchestra floor, and other features. But these and other interesting decorations of the theatre belong to a later age. It was under the administration of Lycurgus the orator (337 B.C.) that the building was first really completed; and many of the sculptures which have been lately brought to light belong to a restoration of the theatre in the 2d, or perhaps even in the 3d, century A.D.[1]

Thesean wall.

Enough has now been said of the condition of Athens before the Persian War. It was surrounded by a ring-wall of narrow circuit, some doubtful traces of which are supposed to remain. At its centre stood the Acropolis, already crowded with temples and sanctuaries, some upon the summit, some built at its foot, and others—like the famous grotto of Pan, on the N.W. slope—mere caves in its rocky sides.

Grotto of Pan.

After the Persian war.

The Persian invasion, which forced the Athenians to take refuge in their "wooden walls," and to leave their city at the mercy of the barbarian, marked an important epoch in the annals of Athenian building. Upon the retreat of Mardonius, the Athenians returned to Attica to find their city virtually in ruins. Its fortifications and public buildings had been destroyed or burnt, and the private dwellings had been wantonly defaced or ruined by neglect. Amid the enthusiasm of hope which followed upon the great deliverance of Greece, a natural impulse led the Athenians to rear their city more glorious from its ruins. Themistocles fanned their patriotism with the foresight of a statesman, and Athens rose again with marvellous rapidity. This haste, however, though creditable to their patriotism, and, indeed, necessary in order to forestall the jealous opposition of Sparta, was not without its evils. The houses were rebuilt on their old sites, and the lines of the old streets, narrow and irregular as they had been, were too readily followed. A similar haste marked the rebuilding of the city walls, a work in which men and women, old and young, took zealous part, not scrupling to dismantle any building or monument, private or public, which could supply materials for the building. But in rebuilding the walls Themistocles gave them a wider circuit, especially towards the N. and N.E. (Thucyd., i. 90, 93). At the same time he determined to construct new harbours, and to fortify the Piræeus, regarding the navy of Athens as her principal source of strength. It is doubtful whether the "Long Walls" formed a distinct portion of his designs; but he may certainly be regarded as the founder of the greatness

Rebuilding of the walls.

[1] The best account yet given of the Dionysiac theatre is to be found in Dr Dyer's recent work on Athens.

of Athens, the works and embellishments carried out by Pericles being only a fulfilment of the far-sighted aims of Themistocles. Thucydides (ii. 13) makes the circuit of the city wall to be 43 stades (about 5¼ miles), exclusive of the unguarded space between walls; this is found to correspond accurately enough with the existing remains. In tracing the circuit of the ancient walls, we may take our start from the N.W. side of the city, at the one gate whose site is absolutely certain, the Thriasian gate (called also the Sacred gate, as opening upon the sacred way to Eleusis, and also τὸ Δίπυλον, as consisting of two gates, perhaps one within the other), which is marked by the modern church of the Holy Trinity, a little N. of the bottom of Hermes Street—a spot attractive to the modern tourist through the beautiful "street of tombs" here laid bare by recent excavations. From the Thriasian gate the wall of Themistocles ran due E. for some distance; thence, skirting the modern theatre, it ran N.E., parallel to the modern Piræus Street as far as the Bank, when it returned in a S.E. direction across the site of the present Mint, as far as the Chamber of Deputies. Thence towards the S.E. it included nearly all the modern Royal Gardens, and then ran S.W., following the zig-zag of the hills above the north bank of the Ilissus, until westwards by a straight course parallel with the Acropolis it reached the Museium Hill. Thence it may be traced in a direction N.W. and N., following more or less the contour of the hills, until we return to our starting-point at the Dipylum gate.

Gates.

Eight other gates (exclusive of wickets, πυλίδες, which must have existed) are mentioned by ancient authors—the Piræan, Hippades, Melitides, Itonian, Diomeian, Diocharis, Panopis, and Acharnian. Their exact sites cannot be certainly fixed, but some of them may be determined within narrow limits, such as the Piræan gate, which led out of the Agora, and opened upon the long walls. Having completed the defences of the city proper, among which must be included the building of the north wall of the Acropolis (Dyer, p. 121), Themistocles proceeded to fortify the Piræus.

The Piræus and its buildings.

Athens, like most of the old Greek towns, was built, for greater security, at a distance from the coast, and only when more settled times brought her greater prosperity was a harbour formed at the nearest bay of Phalerum, near the modern church of St George. It is said that Themistocles would gladly have transported the Athenian population bodily from the upper city to the coast, there to form a great maritime state. Though this was impossible, yet he could strengthen Athens on the seaward side. The isthmus of Piræus, though somewhat more distant than Phalerum, presented obvious advantages as a seaport. It formed on its north side the spacious and secure basin of Piræus (now Port Drako), the north and south shores of which towards the entrance fall back into two smaller bays—harbours within the harbour—known respectively as the κωφὸς λιμήν and κάνθαρος. The neck of the isthmus on the south is formed by Port Zea (now Phanari), the entrance of which was secured by Phreattys, the headland of Munychia. Round to the east of the district of Munychia, again, and facing Phalerum, was the harbour known anciently as Munychia, and now as Port Stratiotiki. Themistocles thus, in giving up Port Phalerum, gave Athens three harbours instead of one. The fortifications of Piræus were conceived on a grand scale, and carried out with no sign of hurry. The whole circuit of Piræus and of the town of Munychia was enclosed alike on the sea and land sides by walls of immense thickness and strength, which were carried up to a height of more than 60 feet—this being only half the height intended by Themistocles! (see Grote, *Hist. Greece*, c. xliv.) The laying out of the new seaport belonged rather to the regime of Pericles (Grote, c. xlvii.) It was then that Hippodamus, the eccentric architect, planned the Agora which bore his name; and the various public buildings which adorned Piræeus doubtless arose with growth of Athenian commerce. The harbour-basin was lined with porticoes, which served as warehouses and bazaars. Two theatres existed in the town, and numerous temples. The local deity was Artemis Munychia; but the large number of foreigners (μέτοικοι) who became naturalised at this port led to the introduction of many foreign forms of worship. Artemis herself came to be identified with the Thracian Bendis, and her festival (τὰ Βενδίδεια) is referred to in the immortal opening of Plato's *Republic*.

Long w[alls].

If not a part of the original designs of Themistocles, it was at least a natural development of them, to carry "Long Walls" from the newly-fortified Piræus to the upper city, and thus combine them both into one grand system of fortification. The experiment of connecting a town by long walls with its port had been already tried between Megara and Nisæa (Grote, *Hist. Greece*, c. xlv.), and it was now repeated on a grander scale under Cimon. From the portion of the city wall between the Museium and the Nymphs' Hill a sort of bastion was thrown out to S.W. so as to form an irregular triangle, from the apex of which a "long wall," about 4 miles long, was carried down to the N. portion of the Piræan fortifications; this was termed τὸ βόρειον τεῖχος. Another "long wall" of somewhat shorter length ran down to the wall of Phalerum, which had hitherto served as the port of Athens; this was τὸ Φαληρικὸν τεῖχος. A third wall, between the two, parallel to the first, and but a few yards from it (τὸ νότιον τεῖχος, τὸ διὰ μέσου τεῖχος), was afterwards added by Pericles, and the maritime fortifications of Athens became complete. But the city owed still more to the munificence of Cimon. Out of the spoils of his Persian campaign he fortified the S. side of the Acropolis with a remarkably solid wall, which terminated in a sort of bastion at the W. end. Here he reared a little temple of Athena Nike (otherwise called the Wingless Victory), although the existing sculptures of the frieze are pronounced on account of their style to belong to a somewhat later date (Pausan., i. 28, 3; Corn. Nep., *Cimon*, ii.; Plutarch, *Cimon*, xiii.)

Wingle[ss] Victory.

It was Cimon who first set the example of providing the citizens with agreeable places for promenade (Plutarch, *ibid.*), by planting the Agora with plane trees, and laying out the Academy with trees and walks. It is probable that some of the porticoes in the Agora were built by Cimon; at all events, the most beautiful one amongst them was reared by Pisianax, his brother-in-law, and the paintings with which Polygnotus, his sister's lover, adorned it (representing scenes from the military history of Athens, legendary and historical) made it ever famous as the Στοὰ ποικίλη.

Stoa Pœcile.

One more building, the most perfect existing relic of ancient Athens, was also built by Cimon. The Theseium (as we still may venture to call it, in spite of the doubts lately cast upon its identification)[1] is a hexastyle Doric temple standing on an eminence due N. of the Areopagus, and is the first object which meets the eye of the tourist who approaches the city from the Piræeus. Having served in Byzantine times for a Christian Church, it is now a museum of antiquities, and contains some of the choicest treasures discovered by recent excavations.

Theseiu[m].

Periclea[n] era.

We have now brought this sketch of Athenian topography down to the most distinguished period of Athenian history and Athenian architecture—the era of Pericles. As the champion of Hellenic freedom against the Persians, as the head of the Ionic confederation, Athens had suddenly grown to be the foremost city in Greece. But when one by one the confederate states sank into the position of subject-

[1] See Dyer, *Athens*, p. 230, *foll.*, who thinks it is really the temple of the Amazons.

allies; when the ἡγεμονία of Athens passed insensibly into a τυραννίς (Thucyd., ii. 63); when the contribution of ships and men was commuted in most cases for a money payment, and the funds of the confederation were transferred from the Apollonium at Delos to the Athenian Acropolis,—an enormous revenue became at the disposal of the Athenian Government. It is to their credit that so little of it found its way into private pockets. It was natural for the thoughts of a Greek, especially of an Athenian, to turn to the decoration of his city; it was politic that the central city of the Ionian confederacy should be adorned with a beauty equal to her prestige. The buildings connected with the name of Cimon had been chiefly for utility or defence; those of Pericles were mainly ornamental. The first edifice completed by him seems to have been the Odeium, on the E. of the Dionysiac theatre, to serve as a place for recitations by rhapsodists, and for musical performances. It was burnt by Aristion during Sulla's siege of Athens, but afterwards rebuilt. Mention has already been made of the building of the Long Walls and the laying out of the Piræeus by Pericles; but it was the Acropolis itself which witnessed the greatest splendours of his administration. Within its limited area arose buildings and statues, on which the genius of Phidias the sculptor, of Ictinus and Mnesicles the architects, were employed for years; while multitudes of artists and craftsmen of all kinds were busied in carrying out their grand designs.[1] The spoils of the Persian War had already been consecrated under Cimon to the honour of the national goddess, in the erection of a colossal statue of Athena by Phidias between the entrance of the Acropolis and the Erechtheium; her warlike attitude gained her the title of Πρόμαχος, and the gleam of her helmet's plume and uplifted spear was hailed by the homeward seaman as he doubled Cape Sunium (Pausan., i. 28). But the national deity was to receive yet greater honours at the hand of Pericles. That an old temple stood on the site afterwards occupied by the Parthenon is proved, less by the doubtful expressions of Herodotus (viii. 51, 55), and the testimony of later compilers like Hesychius, than by recent excavations, which reveal that a large temple must have been at least begun upon this spot when the Persian invaders destroyed the old buildings of the Acropolis by fire. Here, then, Pericles proceeded to rear what has ever since been known as the Parthenon. The designer of this masterpiece of architecture was Ictinus; the foundations of the old temple were at his suggestion extended in length and breadth, and thus arose upon the S. side of the Acropolis a magnificent temple of the virgin goddess. It was completed in the year 438 B.C. It stood upon the highest platform of the Acropolis, so that the pavement of the peristyle of the Parthenon was on a level with the capitals of the columns of the east portico of the Propylæa. The temple was built entirely of white marble from the quarries of Mount Pentelicus. Ascending a flight of three steps, you passed through the great east entrance into the Pronaos, wherein was stored a large collection of sacred objects, chiefly of silver. From the Pronaos a massive door led into the *cella*, called Hecatompedos (νέως ὁ Ἑκατόμπεδος), because it measured in length 100 Attic feet. The treasure here bestowed consisted chiefly of chaplets and other objects of gold. The west portion of the cella was railed off (by κιγκλίδες), and formed the *Parthenon* proper, *i.e.*, the adytum occupied by the chryselephantine statue by Phidias of Athena Parthenos,—a work which yielded the pre-eminence only to one other statue by the same artist, viz., the Zeus at Olympia. In this adytum were stored a number of silver bowls and other articles employed at the Panathenaic festivals. The westernmost compartment at the rear of the cella was the Opisthodomus, which served as the national treasury; hither poured in the tribute of the Athenian allies. It is important to remember that the Parthenon was never intended as a temple of worship; for this purpose there already existed another temple, presently to be described as the Erechtheium,—standing upon the primeval site of that contest between Athena and Poseidon which established the claim of the goddess to the Attic citadel and soil. The Parthenon was simply designed to be the central point of the Panathenaic festival, and the storehouse for the sacred treasure. The entire temple should be regarded as one vast ἀνάθημα to the national deity, not as a place for her worship. Thus directly in front of her statue in the cella there stood an erection, which has been mistaken for an altar, but which is more probably to be regarded as the platform which the victorious competitors in the Panathenaic contests ascended to receive, as it were from the hand of the goddess, the golden chaplets and vases of olive oil that formed the prizes (see Michaelis's *Parthenon*, p. 31). This consideration lends significance to the decorations of the building, which were the work of Phidias. Within the outer portico, along the outside of the top of the wall of the building, ran a frieze 3 feet 4 inches in height, and 520 feet in total length, on which were sculptured figures in low relief[2], representing the Panathenaic procession. Nearly all of these sculptures are in the British Museum, and the entire series has been recently made complete by casts from the other fragments, and arranged in the order of the original design. The marvellous beauty of these reliefs, which was heightened originally by colour, has been long familiar to all the world from numerous illustrated descriptions. The procession of youths and maidens, of priests and magistrates, of oxen for sacrifice, of flute-players and singers, followed by the youthful chivalry of Athens on prancing steeds—is represented as wending its way from the west towards the eastern entrance.[3] Outside of the building, on the N. and S. sides, the metopes between the Doric triglyphs were filled with sculptures representing scenes from the mythical history of Athens. But the glory of the Parthenon were the sculptures of the E. and W. pediments. Unhappily but a few figures remain, and none are wholly perfect, of the statues which formed these groups; and Pausanias appears to have thought it superfluous to give a minute description of objects so familiar to every connoisseur and traveller. The sculptures on the eastern pediment related to the birth of Athena; the central group was early destroyed by the Byzantine Christians in converting the Parthenon into a church, with the Pronaos for its apse. But nearly all the subordinate figures are preserved in a more or less injured condition in the British Museum. The noble head of the horse of the car of Night, the seated female figures of "The Fates," and the grand torso commonly known as the "Theseus," are familiar to us all. It would be out of place here even to enumerate the many attempts that have been made to reconstruct the groups of either pediment. The sculptures on the W. represented the contest between Athena and Poseidon for the possession of Attica; and although scarcely any portions of these figures are now existing, yet they are better known to us than the E. pediment by means of the faithful (if clumsy) sketches made by the Frenchman Carrey in 1674, when they were in a comparatively perfect state. Those who desire to know all that is to be known concerning the sculptures of the Parthenon should consult the beautiful work of Michaelis, *Der Parthenon*, while the

[1] See the animated description in Plutarch, *Pericles*, 12, *foll.*

[2] See the remarks of Mr Ruskin, *Aratra Pentelica*, p. 174.

[3] He who desires to enjoy these sculptures should come from a perusal of Michaelis's eloquent work *Der Parthenon*, and spend a day in the British Museum with the guide-book in his hand.

measurements and architectural details of the edifice have never been so splendidly given as by our countryman Penrose, in his *Principles of Athenian Architecture*.

We will turn now to the other buildings of the Acropolis, none of which, however, are so full of significance as the Parthenon itself. For, indeed, standing as it does on the highest point of Athenian soil, its erection marked the culminating point of Athenian history, literature, politics, and art. The "Birth of Athena," over the eastern entrance, may symbolise to us the sudden growth of Athenian greatness, while in the contest between the armed goddess of peaceful wisdom and the violent god of sea, which adorned the western front, we may see an allegory of the long struggle between the agricultural and the maritime interests which forms the central thread of Athenian history.

Erechtheium. Opposite to the Parthenon, on the northern edge of the Acropolis, stands another remarkable temple, far smaller in size, and built in the most graceful forms of the Ionic order. The Erechtheium appears to be designed expressly to contrast with the severe sublimity of the Parthenon; and on the side which confronts those mighty Doric shafts, the columns of the smaller building are allowed to transform themselves into Canephori. The temple of Athena Polias, which contained the ancient wooden image of the goddess, and formed the centre of her worship, suffered from fire in the Persian War (479 B.C.). A building so sacred would hardly have been allowed to remain for long in ruins; but it was reserved for Pericles to set about a complete restoration of it. However, the Peloponnesian War seems to have interrupted his designs, and in the year 409 B.C. the edifice was still unfinished,[1] and soon after this it was totally destroyed by fire. But soon afterwards it must have been rebuilt, without doubt retaining all its original features. The temple in its present state consists of an oblong cella extending from E. to W. From each side of the W. end of the cella projects a portico, forming a sort of transept. The eastern portico formed the temple of Athena Polias, upon the site of her ancient contest with Poseidon. The west portion was the Pandroseium, dedicated to Athena Pandrosus. The building thus formed two temples in one, and is styled by Pausanias a *διπλοῦν οἴκημα*. It seems at a later time to have been commonly called the Erechtheium, because of a tradition that Erechtheus was buried on this site.

Propylæa. Among the many glories of the Acropolis, the Propylæa are described by Pausanias as being exceptionally magnificent (i. 22). They rivalled even the Parthenon, and were the most splendid of all the buildings of Pericles. The western end of the Acropolis, which furnished, and still furnishes, the only access to the summit of the hill, was about 160 feet in breadth,—a frontage so narrow, that to the artists of Pericles it appeared practicable to fill up the space with a single building, which, in serving the main purpose of a gateway, should contribute to adorn as well as to guard the citadel. This work, which rivalled the Parthenon in felicity of execution, and surpassed it in boldness and originality of design, was begun in the archonship of Euthymenes, in the year 437 B.C., and completed in five years, under the directions of the architect Mnesicles. Of the space which formed the natural entrance to the Acropolis, 58 feet near the centre were left for the grand entrance, and the remainder on either side was occupied by wings projecting 32 feet in front of the central colonnade. The entire building received the name of Propylæa from its forming the vestibule to the five doorways, still in existence, by which the citadel was entered. The wall in which these doors were pierced was thrown back about 50 feet from the front of the artificial opening of the hill, and the whole may therefore be said to have resembled a modern fortification, although, in fact, the Propylæa was designed, not for defence, but for decoration. The whole building was of Pentelic marble. The Megaron or great vestibule in the centre consisted of a front of six fluted Doric columns, mounted upon four steps, which supported a pediment, and measured 5 feet in diameter and nearly 29 in height, with an intercolumniation of 7 feet, except between the two central columns, which were 13 feet apart, in order to furnish space for a carriage-way. Behind this Doric colonnade was a vestibule 43 feet in depth, the roof of which was sustained by six inner columns in a double row, so as to divide the vestibule into three aisles or compartments; and these columns, although only three feet and a half in diameter at the base, were, including the capitals, nearly 34 feet in height, their architraves being on the same level with the frieze of the Doric colonnade. The ceiling was laid upon marble beams, resting upon the lateral walls and the architraves of the two rows of Ionic columns,—those covering the side aisles being 22 feet in length, and those covering the central aisles 17 feet, with a proportional breadth and thickness. Enormous masses like these, raised to the roof of a building, standing upon a steep hill, and covered with a ceiling which all the resources of art had been employed to beautify, might well overcome the reserve of a matter-of-fact topographer like Pausanias, and at once account for and justify the unusual warmth of his language when he is speaking of the roof of the Propylæa (i. 22). Of the five doors at the extremity of the vestibule, the width of the central and largest was equal to the space between the two central columns of the Doric portico in front, and the same also as that between the two rows of Ionic columns in the vestibule; but the doors on either side of the principal one were of diminished height and breadth, and the two beyond these again were still smaller in both dimensions. These five gates or doors led from the vestibule into a back portico 18 feet in depth, which was fronted with a Doric colonnade and pediment of the same dimensions as those of the western or outer portico, but placed on a higher level, there being five steps of ascent from the western to the level of the eastern portico. From the latter or inner portico there was a descent of one step into the adjacent part of the platform of the Acropolis.

The wings of the Propylæa were nearly symmetrical in front, each presenting on this side a wall adorned only with a frieze of triglyphs, and with antæ at the extremities. The inner or southernmost column of each wing stood in a line with the great Doric columns of the Megaron; and as both these columns and those of the wings were upon the same level, the three porticoes were all connected together, and the four steps which ascended to the Megaron were continued also along the porticoes of the two wings. But here the symmetry of the building ended; for, in regard to interior size and distribution of parts, the wings were exceedingly dissimilar. In the northern or left wing, a porch of 12 feet in depth conducted by three doors into a chamber of 34 feet by 26, the porch and chamber thus occupying the entire space behind the western wall of that wing; whereas the southern or right wing consisted only of a porch or gallery of 26 feet by 16, which, on the S. and E. sides, was formed by a wall connected with and of the same thickness as the lateral wall of the Megaron, and, on the W. side, had its roof supported by a narrow pilaster, standing between the N.W. column of the wing and an anta, which terminated its southern wall. In front of the southern or right wing of the

[1] An important inscription in the British Museum gives a survey of the works as they stood in that year, drawn up by a commission appointed for the purpose. See *Greek Inscriptions in the British Museum*, vol. i. No. 35.

Propylæa there stood, so late as the year 1676, the small Ionic temple dedicated to Athena Nike, and commonly known by the ancients as the temple of the Wingless Victory (Νίκη ἄπτερος), which has already been mentioned as probably one of the buildings of Cimon. Perhaps before the 18th century this building was pulled down by the Turks, and the only remains of it—parts of the frieze built into a wall—which were known in his day were carried off by Lord Elgin, and are now in the British Museum. In 1835 careful excavations were made under the directions of Professor Ross, when not only were the remains of the Propylæa opened up far more clearly than before, but also nearly all the fragments of this little temple of Victory were discovered; they had been used for building a Turkish battery, and so preserved. Thus the temple was at once restored by a reconstruction of the original fragments. Few quarters of ancient Athens have received more advantage from judicious excavation in recent years than this western end of the Acropolis.

From the disastrous termination of the Peloponnesian war to the yet more fatal defeat at Chæroneia, the architectural history of Athens is a blank, only interrupted by the restoration of the Long Walls and the rebuilding of the fortifications of Piræeus by Conon, both of which had been destroyed by Lysander. The financial genius of the orator Lycurgus, whose administration lasted from 338 to 325 B.C., replenished to some extent the exhausted resources of his country. He reorganised her finance, he catalogued and rearranged the sacred and national treasuries, and brought order and efficiency into every department of state. This new impulse made itself felt in building activity. The Dionysiac theatre was now first completed; and though, as we have already seen, many of the sculptures and other marbles recently uncovered on its site are the restorations of a very much later age, yet we may confidently assume that in all material points the theatre as we are now able to view it represents the condition of the building as it stood in the time of Lycurgus. Another remarkable work which signalised his administration was the Panathenaic Stadium. On the southern side of the Ilissus, at right angles to the stream, a hollow space was scooped out of the soil, some 680 feet in length and 130 in breadth. It is possible that the site had been used for gymnastic contests before the orator's time; it was he, however, who first undertook to level it properly and lay it out. But it was reserved for the munificence of Herodes Atticus finally to complete it. He furnished the place with magnificent seats of Pentelic marble, tier upon tier, capable of accommodating, at the very least, 40,000 spectators. An attempt was recently made to excavate the Stadium, but it was found that every trace of antiquity had been destroyed, the marble having been used as a quarry for building purposes.

The administration of Lycurgus is an important era in Athenian architecture; for after his time we never seem to hear of any more buildings having been reared by the Athenian Government. The best-known extant edifices of the period immediately following were the work of wealthy private persons. Round the eastern end of the Acropolis, starting from the eastern entrance of the Dionysiac theatre, then leaving the Odeium of Pericles to the left, and thence sweeping westward to the Agora, there ran a street which formed a favourite promenade in ancient Athens, commonly known as the "Street of Tripods." It gained this name from the small votive shrines which adorned it, supporting upon their summit the bronze tripods which had been obtained as prizes in the choragic contests. The tripods thus mounted often themselves served as a frame to some masterpiece of sculpture, such, for example, as the famous satyr of Praxiteles. It had early become the custom to dedicate the prize tripods within the sacred precincts of the theatre; but when this space was filled, they gradually extended all along this street, and their erection was made more and more a matter of private display. One of these shrines still stands, and is well known as the monument of Lysicrates. It bears the following inscription upon its architrave:—"Lysicrates, son of Lysitheides, of the deme Cicynna, was choragus; the tribe Acamantis gained the prize with a chorus of boys; Theon accompanied them upon the flute; Lysiades of Athens taught them; Euænetus was archon." In other words, the date of this monument was 335 B.C. Fifteen years after that a somewhat similar shrine was reared at the topmost summit of the back of the great theatre, where an ancient grotto was by Thrasyllus converted into a choragic monument. The Byzantine Christians transformed the building into a chapel of the Virgin, under the title of Panaghia Spiliotissa, or Our Lady of the Grotto. Early travellers describe this little shrine as consisting of three pilasters engaged in a plain wall, surmounted by an inscribed architrave; above was supported a figure of Dionysus, now preserved, but in a much injured state, in the British Museum. On the top of the statue originally rested the tripod that formed the prize of Thrasyllus.

Monument of Thrasyllus.

Macedonian period.

The Macedonian period again marks a new epoch in the history of Athenian topography. Henceforward almost every embellishment Athens received was at the hands of the various foreign princes, whose tastes inclined them to patronise a city so rich in historical associations, and so ready to reward each new admirer with an equal tribute of servile adulation. But whatever decoration the city might owe to royal vanity or munificence, her connection with these foreign potentates brought her far more of injury than advantage. She became entangled in their wars, and usually found herself upon the losing side.

Upon the death of Alexander, the Athenians claimed their liberty, but they at once had to submit to Antipater (322 B.C.), who placed a garrison in Munychia. It perhaps was he who defaced the ancient Pnyx; at all events, from this time forward the political oratory of Athens became silent for ever. In 318 B.C. Demetrius the Phalerean was made governor of Athens by Cassander, and received every kind of homage from his servile subjects. But as soon as the other Demetrius, surnamed Poliorcetes, appeared in the Piræeus, the Athenians welcomed him with open arms. For restoring to them the forms of democracy he was extolled with abject adulation, and had assigned to him a residence in the Opisthodomus of the Parthenon itself, where he profaned the sanctuary of the virgin goddess with unbridled sensuality. Upon the defeat of Antigonus at Ipsus (301 B.C.), Demetrius fled from Athens, and under Lachares, the leading demagogue of the time, the city enjoyed the shadow of independence. But the demagogue soon developed into a tyrant, and when Demetrius reappeared in 296 B.C. and besieged the city, Lachares had to fly from the indignation of the citizens, taking with him the golden shields that adorned the eastern front of the Acropolis, and having rifled the chryselephantine statue itself. Again, in 268 B.C., Athens endured a long siege from Antigonus Gonatas, who laid waste the surrounding country. Still more disastrous was the ineffectual siege by Philip V. in 200 B.C., who, pitching his camp at Cynosarges, destroyed everything that lay around—the temple of Heracles, the gymnasium there, and the Lyceium as well. At length, in 146 B.C., Greece became a Roman province, and Athens succumbed peacefully to the Roman yoke.

During the inglorious period of Athenian history wh has just been sketched, several new buildings were reared the munificence of foreign princes. Ptolemy Philadelp

gave his name to a large gymnasium—the Ptolemæum—built by him near the Theseium. Attalus I., king of Pergamus, erected a stoa on the north-east of the Agora, and laid out a garden in the Academy. His successor, Eumenes II. (197–159 B.C.), built another stoa near the great theatre. Antiochus Epiphanes designed the completion of the Olympium, a work which was interrupted by his death.

Under the rule of the Romans Athens enjoyed the privileges of a *libera civitas*, *i.e.*, no garrison was introduced into the town, no tribute was levied upon it, and the constitution was nominally left unaltered. The Areopagus, indeed, under Roman influence, recovered some of its ancient power, and was made to take precedence of the more democratic assemblies of the Boule and Ecclesia. The revision also of the laws by Hadrian would, of course, introduce some changes. Yet it may surely be maintained that Athens under the Roman dominion was in a far better position than in the days before the taking of Corinth by Mummius, when she had been at the mercy of each successive Macedonian pretender. The Romans appear to have shown a remarkable respect for the feelings of the Athenian people. It would be superfluous here to recall the warm expressions of admiration which fall from Cicero and Horace when speaking of Athens. A visit to Athens was regarded by the educated Roman as a kind of pilgrimage.[1] One great disaster Athens did indeed undergo at the hands of Rome; this was the siege and plunder of the city by Sulla in the Mithridatic War. Yielding to the threats of the king and the representations of the villainous Aristion, the Athenians had joined the cause of the king of Pontus, and Sulla deliberately resolved to gratify his revenge (Athenæus, v. 47, *foll.;* Plut., *Sulla*, 12). After a protracted siege, in which the inhabitants suffered the extreme of famine, mocked at once by the insolence of Aristion within, and pressed by a remorseless foe without, Athens at length was taken on March 1, 86 B.C. Many of the public buildings (happily not the most important) were overthrown, much of the sacred treasure was rifled by the soldiers, and many works of art, together with the library of Apellicon, containing the collections of Aristotle and Theophrastus, were carried off by the cultivated Sulla. The loss of life was also great: large numbers were butchered by the soldiery, and the Agora of Cerameicus flowed with blood. We are told that Sulla was wont to take credit for having "spared Athens." He did not indeed destroy it, but his conduct on this occasion alone would suffice to fix an indelible stain upon his memory. With this disastrous exception, Athens prospered under the Roman rule, and students from all parts of the Græco-Roman world flocked thither to attend the lectures of the philosophers and rhetoricians, or to view the countless works of art that adorned the city. Athenian society grew more and more academic. The current tone of educated circles was antiquarian even to pedantry.[2] The inscriptions relating to the Roman period clearly reveal to us the chief interests of contemporary Athenian life. Epitaphs in abundance testify to the δεισιδαιμονία which delighted in proper names derived from deities and religious ceremonies,[3] and the pride of genealogical pedantry. Honorary decrees abound to justify the charge of adulation which was the reproach of the later Athenians. But the commonest class of monuments are the gymnastic inscriptions, which give us lists of the students from all quarters who, while pursuing their studies at Athens, enrolled themselves at a gymnasium, and there had the advantage of a social life and regular discipline, which reminds one somewhat of the college system in the English universities.[4]

But enough has now been said of the condition of Athenian society under the Roman rule; it is time to enumerate the embellishments which the city received during this period. It is uncertain at what exact date the Horologium of Andronicus of Cyrrhus was erected, which is generally known as the Tower of the Winds. It is first mentioned by Varro (*De Re Rust.*, iii. 5, 17), and is therefore older than 35 B.C., though certainly not earlier than the Roman conquest. This monument, so familiar to every scholar, is described by Vitruvius (i. 6, 4) as an octagonal tower of marble. It stands at what anciently formed the eastern extremity of the Roman Agora, presently to be described. On each face, beneath the cornice, is sculptured the figure of the wind which blew from the corresponding quarter; on the top of the roof was a pedestal supporting a bronze triton (now destroyed), which was constructed to turn with the wind, and to point out the wind's quarter with a wand which he held in his hand. The sculptured figures of the winds are in good preservation, though of a declining period of art. They represent the four cardinal points and the intermediate quarters between these. Each has his emblems: Boreas, the north wind, blows his noisy conch: Notus, the rainy south wind, bears his water-jar; Zephyrus, the west wind, has his lap full of flowers, and so on Under each figure are the remains of a sun-dial; and besides all these external features, the interior was constructed to form a water-clock, supplied with water from the spring at the Acropolis called Clepsydra. Thus in cloudy weather a substitute was provided for the dial and the sun. Horologium of Andronicus.

The Agora in Cerameicus has already been described, and it was there noticed that the name Cerameicus often appears to be employed alone to denote the Agora. This may be easily accounted for. By the munificence of Julius Cæsar and of Augustus, a propylæum of four Doric columns, which still exist, was reared at the N.E. extremity of the Cerameicus Agora. The space between the central columns is about 12 feet, between the side columns not quite 5 feet. Over the pediment is a pedestal, with an inscription in honour of Lucius Cæsar, the grandson of Augustus, whose equestrian statue it appears to have supported. This propylæum has by some archæologists been regarded as a portico of a temple to Athena Archegetis, to whom we learn, from an inscription on the architrave, that the building was dedicated out of the moneys given by Julius and Augustus. But there can be no reasonable doubt that these columns formed the entrance into a new Agora, dedicated to Athena Archegetis, just as it was customary with the Romans to dedicate a forum to some deity, and intended chiefly, it would seem, for the sale of the olive oil which formed so large and characteristic an export from Athens. This appears to be proved by the lengthy inscription (see Böckh, *Corp. Inscr. Græc.*, No. 355) which exists immediately within the entrance, and contains an edict of the Emperor Hadrian regulating the sale of oil and the duties payable upon it. It is easy to understand how, after the erection of the Roman Agora, the old market would be styled ἡ ἀγορὰ ἐν Κεραμεικῷ or simply Cerameicus, while the new oil-market would be distinguished as the New or Roman Agora.

[1] The beautiful elegy of Propertius, beginning "Magnum iter ad doctas proficisci cogor Athenas" (iv. 21), is worth referring to.

[2] See note in No. 81 of *Greek Inscriptions in the British Museum*, also No. 93.

[3] *Cf. ibid.*, No. 47; and Cumanudes, Ἐπιγραφαὶ Ἀττικῆς ἐπιτύμβιοι, *passim.*

[4] See *Greek Inscriptions in the British Museum*, No. 39, and *foll.* The best account of the condition of Athens under the Romans may be found in a dissertation by H. L. Ahrens, *De Athenarum statu politico*, &c., and another by Professor Dittenberger, *De Ephebia Attica.*

Agora.[1] The "Tower of the Winds," which had previously been erected, formed, with its useful timepieces, an appropriate embellishment at the north-eastern extremity. The market was enclosed by a wall, and it was reserved for Hadrian to complete its decoration by building a magnificent stoa on its northern side. Augustus himself received the honour of a small circular shrine upon the Acropolis, dedicated to Augustus and Roma. His son-in-law Agrippa was honoured by an equestrian statue in front of the Propylæa, the pedestal of which still exists. The Agrippeium was a theatre erected by Agrippa in the Cerameicus. It is possible, moreover, that the Diogeneium—the only gymnasium mentioned in the Ephebic inscriptions of the imperial period—was built about this time. Its site has recently been thought to have been discovered about 200 yards east of the Tower of the Winds. Whatever licentiousness and misgovernment might mark the reign of succeeding emperors, they at all events refrained from doing injury to Athens. It had been proposed to finish the great temple of Zeus Olympius in honour of Augustus, but the design fell through, and it was reserved for Hadrian to finally complete the building of this magnificent temple, some six centuries from the time when the first stone was laid.

rian at ens.

The reign of Hadrian made literally a new era in the history of Athens.[2] For Greece, and especially for Athens, this emperor entertained a passionate admiration. He condescended to hold the office of archon eponymus; in his honour a thirteenth tribe, Hadrianis, was instituted; and the emperor shared with Zeus the title of Olympius, and the honours of the newly-finished temple. While, however, many portions of the city bore witness to his munificence, it was in the south-eastern quarter that most of his new buildings arose, in the neighbourhood of the Olympium. This suburb was accordingly styled Hadrianopolis, or New Athens, to distinguish it from the old city of Theseus and of Themistocles. The arch of Hadrian still stands in a fairly perfect state, and marks the boundary between the ancient town and the new suburb embellished by Hadrian. On the north-western front of the architrave is the inscription αἵδ' εἴσ' Ἀθῆναι Θησέως ἡ πρὶν πόλις; on the other front, αἵδ' εἴσ' Ἀδριανοῦ καὶ οὐχὶ Θησέως πόλις. At the same time many of the older buildings underwent restoration at his command. Nor was his bounty shown in works of building alone. He ceded to the Athenians the island of Cephallenia, and bestowed upon them large presents of money, and an annual largess of corn.

The immediate successors of Hadrian were guided by his example. Antoninus Pius completed an aqueduct which Hadrian had commenced for bringing water into the town from the Cephisus. Marcus Aurelius visited Athens for the purpose of initiation at the Eleusinian mysteries.

odes cus.

The list of distinguished persons who made themselves famous as benefactors of Athens may be said to close with the name of Herodes Atticus the rhetorician. Herodes had counted Marcus Aurelius amongst his pupils, and was sure of a distinguished career at Rome; but, like the friend of Cicero, he preferred the more peaceful atmosphere of Greece and took the surname of Atticus. His ambition was to excel as a sophist, but he owed his fame yet more to the enormous wealth he inherited from his father, which he spent in works of public munificence. Various towns of Greece and even of Italy were enriched by his bounty, but Athens most of all. In addition to his many other benefactions, two architectural works in particular immortalised his name. One was the Stadium, which he adorned with magnificent marble seats. The other was the Odeium (see Pausan., vii. 20), the ruins of which are still to be seen under the south-west of the Acropolis. An odeium resembled a theatre in its general plan and the purposes it served: it differed apparently in being roofed in. The ancient theatres were open to the sky; but the most remarkable feature of this odeium, built by Herodes in honour of his deceased wife Regilla, was its roof of cedar, fragments of which were actually discovered in the excavations made upon this site in 1857.

Tour of Pausanias.

It is a fortunate circumstance that the best and only extant account of ancient Athens came from the pen of a traveller who visited the city just at the time when the munificence of Hadrian and of Herodes had left nothing more to be added to its embellishment. The Odeium of Regilla, indeed, had not been commenced when Pausanias visited Athens, and he describes it later on in his seventh book. We may place his tour through Athens about the year 170 A.D. His manner of description is as methodical as a modern guide-book, and his very knowledge and appreciation of the endless masterpieces of Grecian art prevent him from covering his pages, like some modern tourists, with rapturous word-painting and expressions of delight. He begins his account of Athens (bk. i. ch. i.–ii. § 1) with a description of the Piræeus and the harbours, and his first tour is along the road from Phalerum to the city, where he enters by the Itonian gate, within which he finds a monument to the Amazon Antiope. In his next tour (ch. ii. § 2–ch. v.) he supposes us to start again from Piræeus, and approach the city along the remains of the Long Walls. Thus entering the city by the Piræan gate,[3] he conducts us along the southern side of the old Agora (which he styles the Cerameicus), describing all the buildings that occur upon the way, from the Stoa Basileius and another stoa near it, adorned with a statue of Zeus Eleutherius, in an eastward direction past the temple of Apollo Patrous, the Metroum, the Bouleuterium, and Tholus, and other buildings, which lay at the northern and north-eastern foot of the Areopagus. This walk ends with the mention of the temple Eucleia and the Eleusinium. It is not easy to see why Pausanias here introduces an account of the fountain Enneacrunus and the temple of Demeter and Core, which every archæologist hitherto has placed near the Ilissus, in the south-eastern extremity of the city.[4] In his next walk (ch. xiv. § 5–xviii. § 3), having already described the south side of the Cerameicus Agora, he starts again from the Stoa Basileius, describes the buildings on the west and north of the Agora, and then enters the new or Roman Agora. In this tour he mentions the altar of Mercy, the gymnasium of Ptolemy, the Theseium, the temple of Aglaurus, and the Prytaneium. In his next walk he starts from the Prytaneium, and proceeding eastward (ch. xviii. § 4, xix.), he mentions the temples of Sarapis and of Ileithuia, until, leaving the eastern end of the Acropolis at some distance on his right hand, he passes through the arch of Hadrian, and describes the Olympium and the other buildings of that emperor. This tour included the temple of Aphrodite ἐν Κήποις, the Cynosarges, the Stadium, and other buildings on both sides of the Ilissus. For his next walk he returns again to the Prytaneium (ch. xx.–xxviii. § 3), and enters the Street of Tripods, which leads him to the temple and theatre of Dionysus, which he describes. Thus he at length reaches the western extremity

[1] The name Cerameicus is never used by writers of pre-Roman times for the old market; they always speak of "the Agora." Pausanias uses both words in their more modern meanings respectively.

[2] Many inscribed documents are found, dated "from Hadrian's first visit." See Dittenberger in the *Hermes*, 1872, p. 213.

[3] Curtius and others are probably mistaken in supposing the Dipylum to be the gate intended by Pausanias.

[4] Dr Dyer, in his recent work on Athens, Appendix i., endeavours to explain this difficulty by assuming the existence of two fountains called Callirrhoe, one of which (Enneacrunus) he places on the north-west of the Acropolis.

of the Acropolis, and entering through the Propylæa, he describes in order each object which adorned the summit, with an accuracy fully borne out by recent excavations. His last walk in Athens (ch. xxviii. § 4, xxix. § 1) conducts us through the various buildings at the western base of the Acropolis. From the temple of the Semnæ he passes to the court of the Areopagus, and the mention of this leads him to speak of the other judicial courts of Athens. The rest of his first book is occupied with an account of the suburbs of Athens—the Academy, the sacred way to Eleusis, &c., and the topography of Attica in general.

Subsequent history of Athens.

A few words may suffice to describe the ultimate fate of Athens. In the reign of Valerian the northern barbarians first appeared in the north of Greece, where they laid siege to Thessalonica. This extraordinary apparition having alarmed all Greece, the Athenians restored their city wall, which Sulla had dismantled, and otherwise placed the town in a state of defence sufficient to secure it against a *coup-de-main*. But under Gallienus, the next emperor, Athens was besieged, and the archonship abolished, upon which the strategos or general, who had previously acted as inspector of the Agora, became the chief magistrate. Under Claudius the city was taken, but recovered soon afterwards. Constantine the Great gloried in the title of General of Athens, which had been conferred upon him, and expressed high satisfaction on obtaining from the people the honour of a statue with an inscription,—a distinction which he acknowledged by sending to the city a yearly gratuity of grain. He also conferred on the governor of Attica and Athens the title of Μέγας Δοῦξ, or Grand Duke, which soon became hereditary; and his son Constans bestowed several islands on the city, in order to supply it with corn. In the time of Theodosius I., that is, towards the end of the 4th century, the Goths laid waste Thessaly and Epirus; but Theodorus, general of the Greeks, acted with so much prudence, that he saved the Greek cities from pillage and the inhabitants from captivity, a service which was most gratefully acknowledged. But this deliverance proved only temporary. The fatal period was now fast approaching, and, in a real barbarian, Athens was doomed to experience a conqueror yet more remorseless than Sulla. This was Alaric, king of the Goths, who, under the Emperors Arcadius and Honorius, overran both Italy and Greece, sacking, pillaging, and destroying. Never, indeed, did the fury even of barbarian conquest discharge itself in a fiercer or more desolating tempest. The Peloponnesian cities were overturned; Arcadia and Lacedæmon were both laid waste; the gulfs of Lepanto and Ægina were illuminated with the flames of Corinth; and the Athenian matrons were dragged in chains to satisfy the brutal desires of the barbarians. The invaluable treasures of antiquity were removed; stately and magnificent structures were reduced to heaps of ruin; and Athens, stripped of the monuments of her ancient splendour, was compared by Synesius, a writer of that age, to a victim of which the body had been consumed, and the skin only remained.

After this dreadful visitation Athens sank into insignificance, and became as obscure as it had once been illustrious. We are indeed informed that the cities of Hellas were put in a state of defence by Justinian, who repaired the walls of Corinth, which had been overturned by an earthquake, and those of Athens, which had fallen into decay through age. But from the time of this emperor a chasm of nearly seven centuries ensues in its history; except that, about the year 1130, it furnished Roger, the first king of Sicily, with a number of artificers, who there introduced the culture of silk, which afterwards passed into Italy. The worms, it seems, had been brought from India to Constantinople in the reign of Justinian.

Doomed, apparently, to become the prey of every spoiler, Athens again emerges from oblivion in the 13th century, under Baldwin and his crusaders, at a time when it was besieged by a general of Theodorus Lascaris, the Greek emperor. In 1427 it was taken by Sultan Amurath II.; but some time afterwards it was recovered from the infidels by another body of crusaders under the marquis of Montferrat, a powerful baron of the West, who bestowed it, along with Thebes, on Otho de la Roche, one of his principal followers. For a considerable time both cities were governed by Otho and his descendants, with the title of dukes; but being unable to maintain themselves in their Greek principality, they were at length succeeded by Walter of Brienne, who, soon after his succession, was expelled by his new subjects, aided by the Spaniards of Catalonia. The next rulers of Athens were the Acciajuoli, an opulent family of Florence, in whose possession it remained until 1455, when it was taken by Omar, a general of Mahomet II., and thus fell a second time into the hands of the barbarians. The victorious sultan settled a Mahometan colony in his new conquest, which he incorporated with the Ottoman empire; and Athens, as well as Greece, continued to form an integral part of the Turkish dominions, until the treaty of Adrianople in 1829, following up the provisions and stipulations of the treaty of London, 7th July 1827, established within certain limits the new state of Greece, of which Athens is now the capital.

Modern sieges.

From the period of the Ottoman conquest to the commencement of the insurrection in 1821, Athens was only known in history by two attempts, on the part of the Venetians, to expel the Turks and make themselves masters of the city. The first of these took place in 1464, only nine years after its capture by the Osmanlis, and proved an entire failure. But the second, which was undertaken in 1687, more than two centuries later, was crowned with a temporary and fatal success. In the month of September of that year, Count Königsmark, a Swede in the service of Venice, having disembarked at the Piræeus a force of 8000 foot and 870 horse, forming part of the armament under Francesco Morosini, afterwards doge, marched to Athens, and having summoned the citadel without effect, he erected a battery of heavy ordnance on the hill of the Pnyx, and placing two mortars near the Latin convent at the western foot of the Acropolis, bombarded it for several days. The fire of the cannon was chiefly directed against the Propylæa, and the modern defences below that edifice, whilst the mortars continued, without intermission, to throw shells into the citadel. The consequence was, that the beautiful little temple of Nike Apteros, the frieze of which is now in the British Museum, was completely destroyed by the breaching battery; and the Parthenon, besides being greatly injured by the bursting of the shells, was, towards the close of the attack, almost rent in pieces by the explosion of a powder magazine, which reduced the middle of the temple to a heap of ruins, threw down the whole of the wall at the eastern extremity, and precipitated to the ground every statue on the eastern pediment. The western extremity was fortunately less injured, and a part of the Opisthodomos was still left standing, together with some of the lateral columns of the peristyle adjoining to the cell. But the shock was nevertheless abundantly disastrous; and when the Turks afterwards regained possession of the citadel (from which, on this occasion, they were expelled), they did all in their power to complete the destruction which the Venetians had so vigorously begun, by defacing, mutilating, or burning for lime every fragment of the edifice within their reach.

In the course of the revolutionary war Athens sustained three sieges. The first was laid by the Greeks in 1822. Having carried the town by storm, and driven

the Turks into the citadel, they established a strict blockade of the fortress, which was continued until the advance of the Pasha at the head of 4000 men induced them to abandon their enterprise, and fly, with the Athenians, to Salamis and Ægina. Two months afterwards, the Pasha having left Athens to the defence of 1500 men, the Greeks again ventured to attack the town, and succeeded in obliging the Turks to seek refuge in the citadel, which they forthwith determined to besiege; but, from ignorance and want of means, no progress whatever was made in the operation until they obtained possession of the well which supplied the garrison with water, when the Turks agreed to capitulate upon condition of being immediately embarked with their families and sent to Asia Minor. On various pretences, however, embarkation was delayed from time to time; and when intelligence at length arrived that a large Turkish force was advancing upon Athens, the Palicari, instead of manning the walls and preparing for a vigorous defence, rushed in a body to the houses where the prisoners were confined, and commenced an indiscriminate massacre. For this atrocity it is no palliation to remember that the Greek character had morally suffered from centuries of servitude, and that they had terrible arrears of vengeance to exact. The third siege was laid by the Turks in 1826. The Greeks had left a strong garrison in the Acropolis, with provisions for several months; and a spring of water having been discovered in the cave of Pan, and enclosed by Odysseus within the defences of the citadel, there was no danger of its being starved into a surrender. But the Turks having established batteries near the Pnyx and on the hill of the Museium, and having drawn a line of trenches round the citadel, with the view of intercepting all communication between the besieged and the Greek army, the garrison was hard pressed; and although Colonel Fabvier succeeded in forcing his way through the Turkish lines with 500 men and a supply of ammunition, and thus affording immediate relief, yet the total defeat of the Greek army under General Church at the battle of Athens, fought in the hope of raising the siege, led soon afterwards to the surrender of the Acropolis, which remained in the hands of the Turks until the termination of the revolutionary war.

Present condition.

In 1812 Athens could boast of a population of 12,000 souls, but during the war the greater part of the city was laid in ruins, and most of the inhabitants were dispersed. In 1834 it was declared the capital of the new kingdom of Greece. Great exertions have been made since then to restore the city; streets have been opened, levelled, widened; the ancient sewers have been cleared and repaired, and the marshes of Cephisus drained. Excavations of ancient sites and buildings have been carried out,—chiefly through the efforts of the Archæological Society of Athens, but the antiquaries and scholars of all Europe have anxiously watched their endeavours, and France and Prussia have vied with Great Britain in the prosecution of Athenian discovery. The Theseium has become a treasury of ancient sculpture, and a new archæological museum has been also erected to contain the ever-increasing stores of ancient inscriptions and sculptures. The royal palace is a large building of Pentelic marble, situated in the eastern quarter of the city, on the highest part of the gentle eminence which rises from the level of the Ilissus and Cephisus towards Lycabettus. The University (πανεπιστήμιον) was founded in 1837, and numbers over 1200 students, while its staff of 52 professors includes the names of some of the most learned Greek archæologists in Europe. In fact, the schools and other educational institutions of Athens are very numerous, and thoroughly efficient. The archæological journals of Athens are full of information concerning the progress of excavations, and publish the texts of newly-discovered inscriptions. The population in 1871 was over 48,000, exclusive of the population of the Piræeus, which would bring the total up to about 60,000. The harbour is visited by ships of all nations. A railway connects the Piræeus with the city, and enters the ancient town about half-way between the site of the Dipylum and Piræan gates. The terminus stands in the midst of what once was the Agora in Cerameicus. The principal street is Hermes Street, running from west to east, a little north of the terminus, until it reaches the royal palace. Two other good streets, Athena Street and Æolus Street, traverse this at right angles. The other streets, with the exception of Stadium Street on the N.E., between the chamber of deputies and the University, are generally narrow and winding. Altogether, Athens, like the rest of Greece, is in a condition of increasing prosperity, and reaps the blessings of freedom. It is true that in our own country the ardent philhellenism of forty years ago has cooled down, and Greece is no longer an object of popular and sentimental admiration. Yet never did the scholars of Europe turn with keener zest to the study of her ancient monuments; and if Attica were cleared for ever of brigands, and furnished with satisfactory roads, then in numbers tenfold greater than now would reverent travellers from the west of Europe delight to make their pilgrimage to the birthplace of philosophy, literature, and art.

The following are some of the most important works on the subject:—Leake's *Topography of Athens;* Wordsworth's *Athens and Attica;* Bursian's *Geographie von Griechenland*, and article "Athenæ" in Pauly's *Real-Encyclopädie*, 2d ed.; E. Curtius's *Attische Studien;* Dyer's *Ancient Athens;* Wachsmuth's *Die Stadt Athen in Alterthum.* (E. L. H.)

ATHENS, the name of several towns in the United States of America, the chief of which are the following:—(1.) The capital of a county of the same name in the S.E. of the state of Ohio, finely situated on the Hocking River. It is the seat of the Ohio university, which was founded in 1804. Population of county, 23,768. (2.) The capital of Clarke county, Georgia, on the W. bank of the Oconee River. It is the seat of the Georgia university, which was founded in 1801, and the central town of a large cotton-growing district. Population in 1870, 4251, of whom 1967 were coloured.

ATHERTON, or CHOWBENT, a township in the parish of Leigh and hundred of West Derby, in Lancashire, 200 miles from London. It is one of those places which have grown to wealth and populousness through the extension of the cotton trade. Besides its factories, it has collieries and ironworks. Population in 1871, 7531.

ATHIAS, JOSEPH, a celebrated rabbi and printer at Amsterdam, whose editions of the Hebrew Bible are noted for the general correctness of the text. Although he was a learned Hebraist, there are occasional errors in the points, especially in the edition of 1661, but many of these were corrected in that of 1667. He also printed several editions of the Bible in the corrupted Hebrew spoken by the Jews of Spain, Germany, Poland, and England. He died in 1700.

ATHLETÆ (ἀθληταί), among the Greeks and Romans, was the designation of persons who contended for prizes (ἆθλα) in the public games, exclusive of musical and other contests, where bodily strength was not called into play, though here also the word was sometimes applied, and it was even extended to horses which had won a race, and again metaphorically, *e.g.*, to persons who had exerted themselves in good deeds (ἀθλητὰς τῶν καλῶν ἔργων). On the other

hand, the term was restricted so as to exclude those who, for mere exercise, without the incentive of a prize, practised in the daily gymnastic competitions. For such the name was ἀγωνισταί, and this distinction was the more necessary in the later period of Greek history, when trained athletes became a professional class (400–300 B.C.). Yet it was not the value of the prizes themselves which led men to devote their lives to athletic exercises. That was at most very insignificant. But from the heroic legends of competitions for prizes, such as those at the obsequies of Patroclus (*Iliad*, xxiii. 257, *foll.*), from the great antiquity of the four national games of Greece (the Olympian, Pythian, Nemean, and Isthmian, with the local Panathenæa at Athens), and from the high social position of the competitors in early times, there gradually became attached to victory in one of these games so much glory, that the townsmen of a victor were ready to, and frequently did, erect a statue to him, receive him in triumph, and care for him for the rest of his life. Against specially trained athletes the better class of citizens refused to compete, and the lists of the public games being thus left practically open only to professionals, training became more a matter of system and study, particularly in regard to diet, which was rigorously prescribed for the athletes by a public functionary, styled the Aleiptes, who also had to salve their bodies when practising. At one time their principal food consisted of fresh cheese, dried figs, and wheaten bread. Afterwards meat was introduced, generally beef or pork; but the bread and meat were taken separately, the former at breakfast (ἄριστον), the latter at dinner (δεῖπνον). Except in wine, the quantity was unlimited, and the capacity of some of the heavy weights (βαρεῖς ἀθληταί) must have been, if such stories as those about Milo are true, enormous. Cases of death from apoplexy are not unknown among them. The Tarentine Iccus was an example of the strictest abstinence. Their instruction consisted, besides the ordinary gymnastic exercises of the palæstra, in carrying heavy loads, lifting weights, bending iron rods, striking at a suspended leather sack (κώρυκος) filled with sand or flour, taming bulls, &c. Boxers had to practise delving the ground, to strengthen their upper limbs. The competitions open to athletes were in running, leaping, throwing the discus, wrestling, boxing, and the Pancratium, or combination of boxing and wrestling. Victory in this last was the highest achievement of an athlete, and was reserved only for men of extraordinary strength. The competitors were naked, having their bodies salved with oil. Boxers wore the *cæstus, i.e.*, straps of leather, round the wrists and forearms, with a piece of metal in the fist, which was sometimes employed with great barbarity. An athlete could begin his career as a boy in the contests set apart for boys. He could appear again as a youth against his equals, and though always unsuccessful, could go on competing till the age of 35, when he was debarred, it being assumed that after this period of life he could not improve. It sometimes happened that an athlete would agree to allow his rival to win; but for that and other cases of dishonesty a fine was imposed, and the money expended in erecting statues, called Ζάνες, with warning inscriptions. The most celebrated of the Greek athletes whose names have been handed down are Milo, Hipposthenes, Polydamas, Promachus, and Glaucus. Cyrene, famous in the time of Pindar for its athletes, appears to have still maintained its reputation to at least the time of Alexander the Great; for in the British Museum are to be seen six prize vases carried off from the games at Athens by natives of that district. These vases, found in the tombs, probably, of the winners, are made of clay, and painted on one side with a representation of the contest in which they were won, and on the other side with a figure of Pallas Athena, with an inscription telling where they were gained, and in some cases adding the name of the eponymous magistrate of Athens, from which the exact year can be determined. Among the Romans, fond as they were of exhibitions of physical skill and strength, the profession of athletes was entirely an exotic, and was even under the empire with difficulty transplanted from Greece. The system and the athletes themselves were always purely Greek. (A. S. M.)

ATHLETIC SPORTS. Although this term is undoubtedly derived from the ancient ἀθληταί, the derivation does not exactly indicate its present meaning, inasmuch as our modern athletes are distinctly defined to be amateurs, in contradistinction to professionals. In fact, the former pursue the agonistic art, and should be styled "agonistics," if we may be allowed to invent such a word, rather than athletes. How the pastime came to be thus named in Britain some fifteen years ago it is hard to say. Till about 1860, all exercises wherein the feet played the principal part were rightly styled "pedestrianism." Up to that period all prizes, whether contended for by amateurs or professionals, were invariably in money. As the practice of the pastime, however, rapidly spread amongst the former, it was naturally found they were loth to compete on the same terms with, and for similar trophies as, the latter. Hence arose the modern definition of an amateur athlete, viz., "Any person who has never competed in an open competition, or for public money, or for admission money, or with professionals for a prize, public money, or admission money; nor has ever at any period of his life, taught, or assisted in the pursuit of athletic exercises as a means of livelihood; nor is a mechanic, artisan, or labourer." The moment this definition was brought into force a wide barrier arose between the two classes, and amateurs ceased to compete for money prizes amongst themselves, or against professionals, on any terms, unless they were willing to forfeit their status. A generic term was required for the new pastime, and in lieu of a better it was entitled "athletic sports," and its votaries "athletes." Hence the haphazard origin of the name. The birthplace of the modern pastime was undoubtedly the great universities and the military and public schools. Cricket has always been justly considered the national game of Great Britain during the summer months, and football fills the same position in the winter. For a month or six weeks in spring and autumn the weather and condition of the ground are in a transition state, and fit for neither of these pastimes, and athletic sports step in and appropriately fill the vacuum. About the year 1812 the Royal Military College at Sandhurst inaugurated modern athletic sports; but the example was not followed till about 1840, when Rugby School, Eton College, Harrow School, Shrewsbury Royal School, and the Royal Military Academy, Woolwich, came to the front. Fifteen years later college meetings had become pretty general both at Oxford and Cambridge. Kensington Grammar School had founded the first annual series of gatherings held in London, whilst Cheltenham College led the van amongst English public schools. After a few months' negotiations the first Oxford *v.* Cambridge annual meeting was held in 1864, and is justly considered the premier *réunion* of the whole year, the interest shown and the attendance of spectators being little, if anything, less than at the annual boat race between the same two seats of learning. Two years later the annual amateur championship meeting was founded in London, when the Oxford and Cambridge victors meet representatives from all parts of the United Kingdom, and contend for the "blue ribands" of the various events. The principal athletic society at present in existence is undoubtedly the "London Athletic Club," which takes the lead in all matters pertaining to athletics throughout the United Kingdom. In

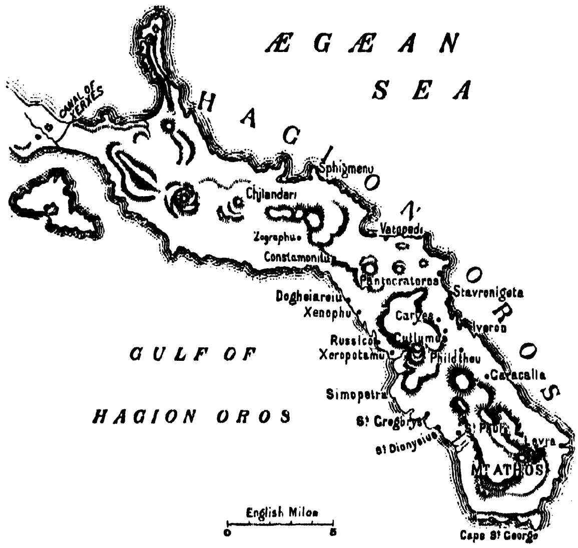
England, moreover, there is now scarcely a country town, sea-side watering-place, cricket, rowing, or football club of importance, and probably not a single university or school, which does not hold its annual gathering for athletic purposes. Across the border the professional still far eclipses the amateur element, and there is no meeting of amateurs which can by any means be compared with the autumn Highland gatherings at Braemar and elsewhere. Until recently the two classes contended indiscriminately together, and the prowess displayed by such amateurs as the late Professor Wilson affords ample testimony that gentlemen were quite capable of holding their own against professionals. The number of annual amateur gatherings held in Scotland is, however, extremely limited, and scarcely extends beyond the universities and chief schools connected with Edinburgh, St Andrews, Glasgow, and Aberdeen. In Ireland the origin of the pastime is again attributable to the leading university, viz., Trinity College, Dublin, where the decision of isolated events, from about the year 1845, has given rise to the meetings now annually held in the picturesque College Park at Dublin. The Irish civil service meeting was inaugurated in 1867, since which time the pastime has made marvellous strides in the island, as is testified by important meetings now held annually in Belfast, Cork, and Galway; whilst the recently formed Irish Champion Athletic Club takes the lead, and stands in the same relation to Ireland as the London Athletic Club does to the whole of Great Britain. Athletic sports are also now extending on the Continent, at many great watering-places where Englishmen are in the habit of congregating. Our great colonies of India, Australia, New Zealand, and Canada, too, as well as the United States of America, Buenos Ayres, China, and even Japan, are not without their annual gatherings for competitors of the Anglo-Saxon race. The contests now classified under the name "athletic sports" are, walking, running, leaping, throwing the hammer, and putting the weight. Leaping and running are respectively identical with the ἅλμα and δρόμος of the ancient pentathlon; whereas throwing the hammer and putting the weight bear some resemblance to throwing the δίσκος. Spear-hurling, ἀκόντιον, is never practised but by a few gymnastic societies; and wrestling, πάλη, between amateurs is rarely witnessed. Running and leaping, however, are nearly always combined on every occasion in two descriptions of contests, viz., steeplechasing and hurdle-racing. Race-walking finds most votaries in London, the northern counties of England, and in Ireland, all distances, from 1 mile to 7, being in vogue amongst amateurs. Running comprises all distances from 100 yards up to 4 miles. Leaping may be divided into three principal heads, viz., running high-leaping, running wide-leaping, and running pole-leaping, which are found to be included in nearly every athletic programme. Adjuncts to these are the running hop-step-and-jump, standing high-leaping, and standing wide-leaping, all of which are favourite pastimes in the northern and midland counties of England. Vaulting, too, is sometimes practised, but belongs rather to the gymnasium than outdoor athletic arena. Steeplechasing proper can only be practised over natural courses across country. Its home is to be found at Rugby School, and amongst members of hare-and-hounds' clubs, who keep themselves in exercise thereby during the winter months. Artificial steeplechase courses are often made on athletic grounds; but the leaps are generally far too sensational, and constructed rather to afford merriment to the spectators than a fair test of the competitors' leaping powers. A prettier sight than a well-contested hurdle race can scarcely be imagined; but few first-class hurdle racers are met with outside the universities and public schools. Scotland is undoubtedly the birthplace both of hammer throwing and putting the weight, yet they are now practised at nearly every English and Irish meeting. 16 ℔ is the usual weight of the missile except in Ireland, where a 42-℔, and sometimes a 56-℔ weight are put, though in a very unsatisfactory fashion. Athletic sports may be practised in a well-rolled grass field, but the best arena is an enclosure, with a regularly laid down running track, the foundation made of clinkers and rubble, and the surface of well-rolled fine cinder ashes. (H. F. W.)

ATHLONE, a market-town and parliamentary borough of Ireland, lying partly in West Meath and partly in Roscommon, 76 miles W. of Dublin. The River Shannon divides the town into two portions, which are connected by a handsome new bridge, opened in 1844. The rapids of the Shannon at this point are obviated by means of a canal about a mile long, which renders the navigation of the river practicable for 71 miles above the town. In the war of 1688 the possession of Athlone was considered of the greatest importance, and it consequently sustained two sieges, the first by William III. in person, which failed, and the second by General Ginkell, who, in the face of the Irish, forded the river and took possession of the town, with the loss of only fifty men. At the time of the last war with France it was strongly fortified on the Roscommon side, the works covering 15 acres and containing two magazines, an ordnance store, an armoury with 15,000 stand of arms, and barracks for 1500 men. There are two parish churches, two Roman Catholic parochial chapels, a Franciscan and Augustinian chapel, Presbyterian, Baptist, and Methodist meeting-houses, a court-house, bridewell, a union work-house, and two branch banks. It has a woollen factory, as well as other industries, and an active trade is carried on with Shannon harbour and Limerick by steamers, and with Dublin by the Grand and Royal Canals and several railway lines, while the importance of its fairs and markets is increasing. There is also a valuable fishery in the river. Market-days, Tuesday and Saturday. The borough returns one member to parliament. Population in 1871, 6566; constituency in 1873, 336.—Thom's *Irish Almanac* for 1875.

ATHOR, ATHYR, HATHOR, the name of the Egyptian divinity corresponding to Aphrodite or Venus. Her name meant "the abode of Hor" or Horus, and she was the mother of that deity in some of his types, and as such a form of Isis, of whom she was a higher or celestial manifestation. Her name occurs as early as the 4th dynasty, when she is styled the mistress of the tree, or sycamore, *neha*, or the tree of the south. Besides the local titles of the different cities over which she presided, she was entitled regent of the gods, living mistress of the upper and lower world, mistress of the heaven and regent of the West, and pupil or eye of Ra, or the Sun, with whom she was connected. In her celestial character she is represented as an Egyptian female holding a sceptre, her head surmounted by the sun's disk, horns, and uræus, and her flesh coloured blue, the colour of the heaven, or yellow, that of gold and beauty (according to Egyptian notions), a term also applied to Aphrodite in Greek mythology. In her terrestrial character she was the goddess who presided over sports and dancing, music and pleasure, like the Greek Aphrodite, the goddess of love; but her particularly special type was the white or spotted cow, the supposed mother of the sun. The solar deities Shu and Tefnut were her children. In certain legends she is mentioned as the seven cows of Athor, which appear in the Ritual or Book of the Dead. These cows, like the *Moiræ*, or fates of Greek mythology, appeared at the births of legendary persons, and predicted the course and events of their lives. It is in this capacity that Athor is connected with Ptah, or the Egyptian Hephæstus, and is allied to Sekhet or Bast, called the wife

or mistress of Ptah, the seven cows being the mystical companions of the Apis, the second life or incarnation of the god of Memphis. She was also represented under the attributes and with the titles of the goddess Nut, or the Egyptian Rhea. The cow of Athor wore on its head the solar disk, and hawk feather plumes, like Amen Ra; and in this character as the great cow she has on some monuments her human head replaced by that of a cow wearing a disk, or the disk and plumes. This emblem also appears in her type at a later period, when her head is represented with long tresses curled into a spiral at the end, and she has the ears of a cow instead of human ears. Her head is then surmounted by a doorway or its cornice, emblem of the abode of the sun, which she represented. This is sometimes surmounted by the disk and horns. The handle of the sistrum, a musical instrument with bars, was generally made in shape of this head and cornice, as were also the capitals of the columns of Abusimbel, Denderah, and other temples, and the ægis and prows of certain arks. As the goddess of beauty and youth, many of the queens of Egypt assumed her type and attributes, and young females after death, at the Ptolemaic and subsequent periods, had their names preceded by that of the goddess, as both sexes had "Osiris" from the period of the 19th dynasty, that of Athor being a later substitute, and for females only. The third month of the Egyptian year was named Athor after her, and the fish *aten* or latus, a kind of carp, was sacred to her. The names and titles of Athor were very numerous, and she is named in the inscriptions the lady or mistress of Silsilis, Abusimbul, Pselcis, Ombos, Hermonthis, Apollonopolis Magna, and Heliopolis; but the chief site of her worship was Denderah, or Tentyris, where she is mentioned under many names, and all the different festivals held in her honour are recorded in the calendar of the temple. Athor is one of the oldest of the Egyptian deities, and her worship continued till the fall of Pantheism and substitution of Christianity. Her worship passed from Egypt to the neighbouring isles, cow-headed figures of the goddess having been discovered in Cyprus. Her figures and representation are common. Jablonski, *Panth.*; Wilkinson, *Manners and Customs*, iv. 387; Birch, *Gall. Antiq.*, p. 25; Duemichen, *Baurkunde der Dendera*, Leip. 1865. (S. B.)

ATHOS is, strictly speaking, the terminal peak of the most eastern of the three peninsular promontories which stretch south from the coast of Turkey (*Macedonia*), like the prongs of a trident, into the Archipelago. The name is, however, frequently extended to the whole peninsula which was formerly known as Acte. The peak rises like a pyramid, with a steep summit of white marble, to a height of 6780 feet, and can be seen at sunset from the plain of Troy on the one hand, and on the other from the slopes of Olympus. The whole peninsula is remarkable for the beauty of its scenery, with rocky heights and richly wooded flanks, ravines "embowered from the light," and glimpses or free outlook over the surrounding sea. The climate is for the most part healthy and pleasant, though the western side is perhaps too much exposed to the heats of summer; and Lucian assures us that in ancient times the inhabitants were famous for longevity. Several towns, such as Sane, Dium, Olophyxus, Cleonæ, are mentioned by Greek and Latin writers as existing in the Peninsula; but none of them seem to have attained any great importance, and the most remarkable event in the ancient history of Athos is the construction by Xerxes of a ship-canal across the isthmus between the outer sea and the Singitic gulf. Traces of this canal, which was regarded by Juvenal as a Greek myth, have been found almost right across the neck of land, and leave no doubt of the truth of the story. In more modern times the district of Athos has been famous for the number of hermits and monks that have found shelter in its retreats. No fewer than 935 churches, chapels, and oratories are said to exist, and many of the communities possess considerable wealth. It is believed that, with the exception of the dwellings of Pompeii, some buildings in



Sketch-Map of Athos.

Athos are the oldest specimens of domestic architecture in Europe; the shrines are in many cases richly decorated with goldsmith's work of great antiquity; the wealth of the monastic libraries in illuminated manuscripts has long been celebrated; and nowhere, according to Mr Tozer, can the Byzantine school of painting be studied with equal advantage. The date of the oldest religious foundation in the peninsula is not clearly ascertained, and the traditional chronology of the monks themselves can hardly be trusted. A bull of Romanus Lecapenus speaks of the restoration of the monastery of Xeropotamu in 924, and as early as 885 a rescript of Basil the Macedonian forbids the molestation of the "holy hermits." Lavra, on Mount Athos proper, was founded by St Athanasius in 960; the village of Caryes, or "The Hazels," was appointed as the seat of government about the same time; and shortly afterwards there followed the establishments Iveron (τῶν Ἰβήρων), Vatopedi (βατοπέδιον), and Sphigmenu (τοῦ Ἐσφιγμένου). The family of the Comneni (1056-1204) bestowed great privileges on the existing monasteries, and added to their number. In the reign of Alexius the first purely Slavonic monastery (that of Chilandari) was founded by the Servian prince Stephen Nemenja. The taking of Constantinople by the Latins in 1204 brought persecution and pillage on the monks; this reminded them of earlier Saracenic invasions, and led them to appeal for protection to Pope Innocent III., who gave them a favourable reply. Under the Palæologi they recovered their prosperity, and were enriched by gifts from various sources. In the 14th century the peninsula became the chosen retreat of several of the emperors, and the monasteries were thrown into commotion by the famous dispute about the mystical Hesychasts. Their numbers were gradually increased by the foundation of St Dionysius, Simopetra, Constamonitu, Russico, St Paul. In the 15th century the monks made terms with the Turkish conqueror Amurath, and have since been molested by none of the sultans, except Soliman the Magnificent, who laid waste some parts of the peninsula. In 1545 Stavroniceta, the last monastery, was added to the list. The hospodars of Wallachia, who were recognised as the protectors of Athos, enriched the communities with lands; but a process of secularisation was commenced by

Baffin
Bay
Canary

Capodistrias, who confiscated their holdings in Greece; and more recently they have been stripped of their possessions in the Danubian principalities. They still retain some property in parts of the Archipelago. A Turkish official resides at Caryes, and collects the taxes, which amount to about ten shillings a head; but for the most part the peninsula is autonomous, being governed by an administrative body of four presidents (ἐπιστάται), one of whom bears the title of "First Man of Athos," and a representative body called the Holy Synod, which consists of twenty members, one from each of the monasteries proper. These twenty communities are partly Cœnobitic, with a common stock and a warden, and partly Idiorrhythmic, with a kind of republican government and great individual liberty. Besides these regular monasteries, there are a number of ἀσκητήρια, or sketes, which consist of several small associations gathered round a central church, and numerous little communities known as καθίσματα, or retreats, as well as genuine hermitages. Harmony is not always maintained between the different establishments, as was shown by a bitter dispute about a water-course between Cutlumusi and Pantocratoros, which led to the interference of the British consuls of Salonica and Cavalla, in answer to an appeal from some Ionian monks who were British subjects (1853). For the most part, however, the inhabitants of Athos are quiet and moderately industrious. They are said to number about 3000, all men; for no female, even of the lower animals, is permitted to desecrate the precincts of the Holy Mountain.

ATHY, a market-town of Ireland, county of Kildare, 34 miles S.W. of Dublin. It is a station on the Great Southern and Western Railway, and is intersected by the river Barrow, which is here crossed by a bridge of five arches. It has a church, a Roman Catholic chapel, a Presbyterian and a Methodist meeting-house, court-house, jail, two banks, hospital, dispensary, barracks, &c. Adjoining the town is a small chapel, an ancient cemetery, and a small Dominican monastery. Previous to the Union it returned two members to the Irish parliament. The principal trade is in corn, which is ground at the neighbouring mills. Population in 1871, 4510.

ATINA, a town of Naples, province of Terra di Lavoro, near the Melfa, and 12 miles S.E. of Sora. It has a cathedral, convent, and hospital, with about 5000 inhabitants; but it is chiefly remarkable for its ancient remains, consisting of portions of its walls, the ruins of an extensive aqueduct, and numerous other structures, besides monuments and inscriptions. The city is of great antiquity, and was a place of importance down to the days of the Roman empire. It is remarkable now, as of old, for the exceptional coolness of its situation.

ATITLAN, a lake in the department of Solola, in Guatemala, 20 miles long, with an average breadth of 9 miles. It seems to occupy the crater of an extinct volcano, and its depth is reported to be very great. The scenery in the neighbourhood is striking and picturesque, the volcano of Atitlan rearing its head 12,500 feet above the level of the sea. A little Indian town, Santiago de Atitlan, nestles at the foot of the mountain.

ATLANTA, the capital of Georgia, one of the United States of North America, is situated about 7 miles to the S.E. of the Chattahoochee River, at an elevation of 1100 feet above the sea. Laid out in 1845, and incorporated as a city in 1847, it has since rapidly increased. It is the centre of a large trade in grain and cotton, and has extensive railway communication in all directions. Engineering work of various kinds is carried on, as well as the manufacture of cast-iron, flour, and tobacco. There are two national and two savings banks. Educational institutions are numerous, and comprise the North Georgia Female College, Oglethorpe College, a medical college, a university for men of colour, and a variety of schools. The state library contains upwards of 16,000 volumes. There are about thirty churches of different denominations, the Methodists being most largely represented, and one of their churches ranking among the finest buildings in the city. During the war Atlanta was the centre of important military operations, and suffered greatly in consequence (1864). It was strongly fortified by the Confederates, and defended, first by General Joseph E. Johnston, and then by General Hood, against the attack of General Sherman. Hood was compelled to evacuate the city, and Sherman afterwards retired to Chattanooga,—movements which occasioned the destruction by fire of the greater part of the buildings, both public and private. Population—(1860), 9554; (1870), 21,789.

ATLANTIC OCEAN

Plate I.

THE designation Atlantic Ocean, originally given to the sea that lies beyond the great range of Atlas in North-western Africa, has come to be applied, with the extension of geographical knowledge, to the whole of that vast ocean which occupies the wide and deep trough that separates the New from the Old World. Its limits are variously defined; some geographers regarding it as extending from pole to pole, whilst others consider it as bounded at its northern and southern extremities by the Arctic and Antarctic circles respectively. As the peculiarity of the physical conditions of the Polar Seas renders it on every account more appropriate to describe them under a separate head (Polar Regions), the Atlantic will be here treated as bounded at the north by the Arctic circle, which nearly corresponds with the natural closing-in of its basin by the approach of the coasts of Norway and Greenland with Iceland lying between them; while at the south, where the basin is at its widest, its only boundary is the Antarctic circle. The line which separates its southern extension from the Indian Ocean may be considered to be the meridian of Cape Agulhas, the southernmost point of the African continent; whilst the boundary between the South Atlantic and South Pacific would be formed in like manner by the meridian of Cape Horn. Although the Baltic and the Mediterranean are commonly regarded as appendages to the Atlantic, yet their physical conditions are so peculiar as to require separate treatment. (See Baltic and Mediterranean.)

Every physical geographer who has written upon the Atlantic has noticed the curious parallelism between its eastern and its western borders,—their salient and retiring angles corresponding very closely to each other. Thus, beginning at the north we see that the projection formed by the British Islands (which extends much further westwards at 100 fathoms below the surface than it does above the sea-level), answers to the wide entrance to Baffin's Bay;

whilst, on the other hand, the projection of the American coast at Newfoundland answers to the Bay of Biscay. Further south, the great rounded prominence of Northern Africa corresponds with the vast bay that stretches from Nova Scotia to St Thomas; whilst the angular projection of South America towards the east corresponds with that receding portion of the mid-African coast-line which is known as the Gulf of Guinea.

This correspondence suggested to Humboldt the idea that the Atlantic basin was originally excavated by a very violent rush of water from the south, which, being repulsed by the mountain ranges of Brazil, was directed by them towards the coast of Africa, and formed the Gulf of Guinea; being there checked and turned to the west by the mountains of Upper Guinea, the stream excavated the Caribbean Sea and the Gulf of Mexico; and issuing thence, it ran between the mountains of North America and Western Europe, until it gradually diminished in velocity and force, and at length subsided. Another writer speaks of the basin of the Atlantic as an immense rift, made by some terrible force, which rent the surface-land asunder, but left the edges of the ravine to show by their form that they had once been connected. For neither of these speculations, however, is there the smallest foundation in fact. What has to be accounted for, indeed, in regard to either of the great areas at present covered by water, is not so much the excavation of its sea-bed, as its segregation from an ocean originally universal by the boundaries that now enclose it; in other words, not so much the depression of the bottom of its basin as the elevation of its sides. Not only is the proportion of the land-surface of the globe to its water-surface scarcely more than one-third (being as 1 to 2·78), but the entire mass of the land which thus covers little more than one-fourth of the surface of the globe is quite insignificant in comparison with that of the water which covers the remaining three-fourths. For whilst the average elevation of the whole land is certainly less than one-fifth of a mile, giving from 9 to 10 millions of cubic miles as the total mass of land that rises above the sea-level, the average depth of the sea (so far as at present known) may be taken at about 2 miles, giving a total of nearly 290 millions of cubic miles of water, which is therefore about *thirty times* the mass of the land. From the computation of Keith Johnston, it appears that, "if we conceive an equalising line, which, passing around the globe, would leave a mass of the earth's crust above it, just sufficient to fill up the hollow which would be left below it, this line would then fall nearly a mile below the present level of the sea." This is tantamount to saying that, if the solid crust of the earth could be conceived to be smoothed down to one uniform level, its entire surface would be covered with water to the depth of about a mile. Hence it is obvious that as the elevation of that crust into land over certain areas must be accompanied by a corresponding depression of the sea-bed over other areas, such depression, augmenting in those areas the previous depth of the aqueous covering of the globe, would be quite sufficient to account for the existence of the great oceanic basins, without any excavating action. And a confirmation of this view is found in the fact, ascertained by recent soundings, that the deepest local depressions of the sea-bed are met with in the neighbourhood of islands that have been raised by volcanic agency. Further, as the quantity of solid matter that must have been removed (on Humboldt's hypothesis) in the excavation of the Atlantic valley must have been nearly four times as great as that which forms the whole known land of the globe, and as it is impossible to conceive of any mode in which such a mass can have been disposed of, we may dismiss that hypothesis as not only untenable in regard to the Atlantic basin, but as equally inapplicable to any other valley of similar width and depth.[1]

The general direction of geological opinion, indeed, has of late been, on physical grounds, towards the high antiquity of the great oceanic basins, not exactly as at present bounded, but as areas of depression having the same relation as they have now to the areas of elevation which form the great continents. Thus Sir Charles Lyell was strongly impressed by the fact that the mean depth of the sea is not improbably fifteen times as great as the mean height of the land; and that depressions of the sea-bottom to a depth of three miles or more extend over wide areas, whilst elevations of the land to similar height are confined to a few peaks and narrow ridges. Hence, he remarked, "while the effect of vertical movements equalling 1000 feet in both directions, upward and downward, is to cause a vast transposition of land and sea in those areas which are now continental, and adjoining to which there is much sea not exceeding 1000 feet in depth, movements of equal amount would have no tendency to produce a sensible alteration in the Atlantic or Pacific Oceans, or to cause the oceanic and continental areas to change places. Depressions of 1000 feet would submerge large areas of the existing land; but fifteen times as much movement would be required to convert such land into an ocean of average depth, or to cause an ocean three miles deep to replace any one of the existing continents."[2] And Professor Dana, who, more than any other geologist, has studied the structure of the existing continents and the succession of changes concerned in their elevation, has been led, by the consideration of the probable direction of the forces by which that elevation was effected, to conclude that the defining of the present continental and oceanic areas began with the commencement of the solidification of the earth's crust. "The continental areas are the areas of least contraction, and the oceanic basins those of the greatest, the former having earliest had a solid crust. After the continental part was thus stiffened, and rendered comparatively unyielding, the oceanic part went on cooling, solidifying, and contracting throughout; consequently, it became depressed, with the sides of the depression somewhat abrupt. The formation of the oceanic basins and continental areas was thus due to 'unequal radial contraction.'" In the opinion of Professor Dana, there has never been any essential change in the relations of these great features. "It is hardly possible," he says, "to conceive of any conditions of the contracting forces that should have allowed of the continents and oceans in after time changing places, or of oceans, as deep nearly as existing oceans, being made where are now the continental areas; although it is a necessary incident to the system of things that the continental plateaus should have varied greatly in their outline and outer limits, and perhaps thousands of feet in the depths of some portions of the overlying seas, and also that the oceans should have varied in the extent of their lands." . . . "The early defining, even in Archæan times, of the final features of North America, and the conformity to one system visibly marked out in every event through the whole history—in the positions of its outlines and the formations of its rocks, in the character of its oscillations, and the courses of the mountains from time to time raised—sustain the statement that the American continent is a regular growth. The same facts also make it evident that the oceanic areas between which the continent

[1] The case of such a shallow trough as that of the English Channel, of the former continuity of whose sides there is ample evidence, whilst its bottom is nowhere 500 feet beneath the surface, is obviously altogether different. The extraordinary depth of the Mediterranean basin, on the other hand, affords strong reason for regarding it as, like the Atlantic, a portion of the original area of depression, circumscribed by the elevation of its borders.

[2] *Principles of Geology*, 11th ed. vol. i. p. 269.

lies have been chief among the regions of the earth's crust that have used the pent-up force in the contracting sphere to carry forward the continental developments. If this was true of the North American continent, the same in principle was law for all continents."[1]

Dimensions of the Atlantic.—The length of the Atlantic basin, considered as extending from the Arctic to the Antarctic circle, is nearly 8000 geographical miles. The nearest approach of its boundaries is between Greenland and Norway, whose coasts are only about 800 miles apart. They thence recede from each other towards the south, as far as the parallel of 30° N. lat., where, between the peninsula of Florida and the western coast of Marocco, there is an interval of 70° of longitude, or about 3600 geographical miles. The channel then rapidly narrows as it passes southward, so that between Cape St Roque in Brazil (5° S. lat.) and the coast of Sierra Leone (between 5° and 8° N. lat.) the African and American continents approach within 1500 miles of each other. The sudden eastward recession of the African coast as it approaches the equator, and the westward trend of the South American coast-line between Cape St Roque and Cape Horn, widen out the South Atlantic basin to the same breadth as that of the North Atlantic in the parallel of 30° N.,—the interval between the Cape of Good Hope and the estuary of La Plata, in the parallel of 35° S., being no less than 73½° of longitude, or about 3600 geographical miles.

The depth of the North Atlantic has been more carefully and systematically examined than that of any other oceanic basin; and the general contours of its undulating sea-bed may now be regarded as pretty well determined. Putting aside the older soundings as utterly untrustworthy, and accepting only those taken by the modern methods, whose reliability has been amply tested by the accordance of diversified experiences, we can now assert with confidence that scarcely any portion of its floor has a depth exceeding 3000 fathoms, or about 3·4 miles, the greatest depth determined by the recent "Challenger" soundings, which was that of a limited depression about a hundred miles to the north of St Thomas, having been 3875 fathoms, or about 4·4 miles. Except in the neighbourhood of its coast-lines, and in certain shallower areas to be presently specified, the floor of the basin at its widest part seems to lie at a depth of from 2000 to 3000 fathoms, its slopes being extremely gradual. The central portion of the principal basin of the North Atlantic, however, is occupied by a plateau of irregular shape, of which a considerable part lies at a less depth than 2000 fathoms. Of this plateau the Azores may be regarded as the culmination; and that group being taken as its centre, it may be said to extend to the north as far as lat. 50°, and to the south-west as far as the tropic of Cancer. The northern extension of this plateau narrows out into a sort of isthmus, which connects it with the plateau that occupies a great part of the Atlantic basin to the north of 50° N. lat.; and it is across this isthmus, and along the bottom of the deep narrow valley on either side of it, that the telegraph cables are laid between Ireland and Newfoundland. Whether its south-western prolongation, known as the "Dolphin Rise" (fig. 1, *infra*), extends to the equator, so as to become continuous with the elevated area which culminates in St Paul's rocks, and by a further southward extension becomes continuous either with the volcanic elevation of St Helena and Ascension Island, or with the elevation in the middle of the South Atlantic which culminates in the island of Tristan da Cunha (fig. 2), has not yet been ascertained. According to the view already suggested as to the formation of the Atlantic basin, the plateau might be regarded as representing the original sea-bed (from which the Azores have been lifted up by volcanic action), whilst the deep valleys on either side of it are "areas of subsidence" answering to the "areas of elevation" of the land that borders them.

Generally speaking, the depths of these valleys increase pretty rapidly with the distance from the shore-line, so that the contour-lines of one and two miles follow the shore-lines pretty closely. But there are two localities in which shallow water extends to a much greater distance from land than it appears to do elsewhere. One of these lies in the neighbourhood of the British Isles. For a distance of about 230 miles to the westward of Ireland there is a slope of only about 6 feet in a mile; but in the next 20 miles there is a fall of 9000 feet, after which there is little change of level for 1200 miles. Hence as the depth of the sea immediately surrounding the British Isles is nowhere 100 fathoms (so that an elevation of their whole area to that amount would unite these islands not only to each other but also to the continent of Europe), it is obvious that the platform on which they rest is really, although now submerged, a part of the land-mass of Europe. Another of these extensive shallows is that of which the Banks of Newfoundland form the highest part; and of the existence of this a probable explanation may be found in the accumulation of the rock-masses that are brought down by icebergs every summer from the coasts of Greenland and Labrador. For it is now generally admitted that these icebergs are really parts of glaciers, that were originally formed on the mountain-slopes of Greenland and Labrador, and then descended valleys which open out on their coasts, so as, on arriving at the mouths of these valleys, to detach themselves and float away, being borne southwards by the Polar Current to be presently described. Most Arctic icebergs of which a near view can be obtained are observed to have upon them a considerable number of pieces of rock, sometimes of a very considerable size; and these are of course deposited on the sea-bed when the icebergs melt (which they usually do on the borders of the Gulf Stream), thus forming a vast conglomerate bed, to which parallels are not improbably to be found in various geological epochs.

Geological Age of the Atlantic Basin.—Guided by the principle that great oceanic basins are to be considered rather as original marine areas that have been limited by the elevation of their boundaries, than as having been formed by the excavation of terrestrial areas, we have to inquire what evidence there is that the basin of the Atlantic has undergone any considerable change within a comparatively recent period.

As has been pointed out by Prof. Wyville Thomson (*Depths of the Sea*, p. 473), it is difficult to show that any oscillations have occurred in the north of Europe since the termination of the Secondary period, to a greater extent than from 4000 to 5000 feet,—this being the extreme vertical depth between the base of the Tertiaries and the highest point at which Tertiary or post-Tertiary shells are found on the slopes and ridges of mountains. Such oscillations, while considerably modifying the boundaries of the Atlantic, would not seriously affect the condition of the deeper parts of its sea-bed; and hence it may be concluded that the two deep valleys, one on the European side of the modern volcanic platform of the Azores, and the other on the American, each having a width of 600 or 700 miles, and an average depth of 15,000 feet, could neither have been formed by such oscillations, nor could, when once formed, have been converted into dry land. It will be presently shown that this idea of the existence of an Atlantic basin corresponding generally to that now existing, as far back as the later Secondary period, is strongly supported by the evidence

[1] "On some Results of the Earth's Contraction from Cooling," in *Amer. Journ. of Science*, June 1873.

recently obtained of the continuity of animal life on the Atlantic sea-bed from the Cretaceous epoch to the present time.

Important information as to the changes which the sea-bed of the Atlantic has undergone within the later geological periods, may be gathered from the structure of the islands which lift themselves above its surface. Along its eastern border, at no considerable distance from the coast of North Africa, there are three principal groups,—the Madeiras, Canaries, and Cape Verd,—all of which have an evidently volcanic origin, and rise up from the eastern slope of the basin, where it is progressively shallowing towards its continental shore-line. Further out, in mid-ocean, lies the group of the Azores, which also is volcanic, and rises from the plateau already spoken of; but between this area and the slope from which the Madeiras and Canaries are based is a very deep channel, ranging downwards to at least 15,000 feet; and a like depth is also found between the Azores and the coast of Portugal. The structure of all these groups of islands gives obvious indications of their formation by separate igneous eruptions in a sea of great depth; and the earliest of these eruptions seems to have taken place in the later Miocene period. As soon as the first solid lavas raised their heads above water, and were thus exposed to the action of the waves, fragments were detached and rounded on the shore; and these being swept off, with the *débris* resulting from their attrition, formed deposits of various kinds upon the slope of the cone, in which corals, shells, &c., were embedded. These fossiliferous deposits have been subsequently elevated to heights of from 1500 to 2000 feet above the level of the sea, showing a rise of the base of the craters; progressive additions have been made to their upper part by the piling up of basaltic and trachytic lavas.[1] That this state of activity still continues is proved by the fact that in 1811 a new island was temporarily formed in the Azores group, off St Michael, by the throwing-up of ashes, and the formation of a cone about 300 feet high, with a crater in the centre. This island, to which the name Sabrina was given, was soon washed away by the waves. And only a few years since, another submarine eruption in this neighbourhood was indicated by earthquakes, jets of steam and columns of smoke, and floating masses of scoriæ. All these considerations concur (as Sir Charles Lyell, *loc. cit.*, justly urges) to negative on geological grounds the hypothesis which has been advocated by some eminent naturalists, that the Azores, Madeiras, and Canaries are the last remaining fragments of a continuous area of land which once connected them with the west of Europe and North Africa.

Proceeding to the south of the equator, we meet with similar evidence of volcanic activity in the structure of the only two islands, Ascension and St Helena, which lie near the line stretching from the Cape Verd group to the Cape of Good Hope; and these also arise from a plateau of considerably less depth than the circumjacent area whose eastern slope gradually shallows to the coast of South Africa. This plateau stretches in a north-westerly direction towards the equator, so as to meet it in from 20° to 22° W. long.; and here indications of volcanic activity—earthquakes, troubled water, floating scoriæ, and columns of smoke—have been several times observed since the middle of the last century, betokening the probable formation of an island or an archipelago in that locality.

Nearly midway between the southern prolongations of the African and American continents, the solitary peak of Tristan da Cunha (fig. 2) lifts itself above the ocean; this also is volcanic, and seems to rise from a broad base of general elevation, resembling the plateau of the North Atlantic.

[1] See Sir C. Lyell's account of them in his *Principles of Geology*, 11th ed. p. 407, *sqq*.

The entire chain of the Greater and Lesser Antilles, which stretches from the delta of the Orinoco to the peninsula of Florida, and forms the eastern boundary of the Caribbean Sea, seems to have been in like manner elevated by volcanic action. That this elevation, like that of the groups of islands on the eastern side of the Atlantic, took place for the most part during the later Tertiary period, is shown by the occurrence of shells, corals, &c., of upper Miocene age, in the upraised sedimentary beds of several of the islands; while the presence of "fringing reefs" of coral around the shores of many of the West India islands is an indication that they lie in an area in which elevation is still proceeding. The channels by which they are separated are so deep as to render it very unlikely that there was ever a continuity of land between them; and the occasional recurrence of earthquakes and volcanic eruptions at different points of this "line of fire," shows that the plutonic action by which the islands were raised is still going on beneath.

The case is very different, however, in regard to the Bermuda group, which constitutes a singular exception to the general fact of the absence in the Atlantic of those coral islands that are so numerous in the Pacific. This group consists of about 300 islands, of which, however, only five are of any considerable size; and these rise from a shoal or platform of about 23 miles long by 13 miles broad, the channels between the islands being very shallow, while at a small distance from the edge of the shoal, the bottom rapidly deepens to 15,000 feet. The islands are entirely composed of upraised beds of coral, shells, &c. (the highest elevation being only about 180 feet above the sea-level); and the shoal itself appears to have the like structure throughout, no traces of any other rock than a limestone formed by the metamorphoses of coral being anywhere met with. Hence, as this insular platform proves to be the summit of a submarine column of 15,000 feet high, rising from a very small base, and as nothing we know of the structure of mountains—volcanic or other—would justify us in supposing that a column of such a height could be formed in any other way than by coral growth, the structure of the Bermuda group would seem to indicate a progressive subsidence of the bed of this part of the Atlantic during its formation, corresponding to that which (according to the well-known views of Mr Darwin) is at present in progress over a large area of the Pacific. It is probable that this coral growth was determined in the first instance by the existence of a submarine mountain, of which the summit lay near the surface, or lifted itself above it; that as soon as this came to be submerged, the coral formation commenced; and that by its continued growth at the summit, at a rate equal to that of the subsidence of its base, the platform has been kept up to the sea-level. The slight elevation which has raised its highest portion above that level may not improbably have taken place in connection with the much larger recent elevations already referred to.

Thus, then, we have evidence of considerable recent local modifications in the level of the Atlantic sea-bed, without any such change as would affect its general character as an ocean basin; while all geological probability seems in favour of the remoteness of the principal depression of the Atlantic area, even if we do not regard it as dating back to the period when the surface of the globe was first undergoing solidification.

Currents of the Atlantic.—By the term "current" will be here meant that *sensible* movement of ocean water in particular directions which can be generally traced, directly or indirectly, to the action of wind upon its surface. A

current thus directly impelled by wind is termed a "drift-current," whilst a current whose onward movement is sustained by the *vis a tergo* of a drift-current is called a "stream-current." But there is another source of current-movement, which has been overlooked by most writers on this subject, namely, the indraught which necessarily takes place to keep up the level of any area from which the surface-water is constantly being drifted away. Such currents, which may be designated as "indraught" or "supply currents," complete the "horizontal circulation" that must necessarily take place in any oceanic area of which one part is subjected to the action of a wind almost constantly blowing in the same direction. Of such a circulation we have a very characteristic example in the South Atlantic, the principal currents of which we shall see to be very easily accounted for.

The initial movement of the current-system, alike of the North and of the South Atlantic, is given by the trade-winds, which are continually driving the water of the inter-tropical region from the African towards the American side of the basin, so as to produce what is known as the *Equatorial Current*. The position of the northern and southern boundaries of this current shifts, like the area of the trade-winds, in accordance with the northward and southward declination of the sun;—a steady westward drift being generally met with to the north of the tropic of Cancer in the summer of the northern hemisphere, and to the south of the tropic of Capricorn in the summer of the southern, whilst in the winter of each hemisphere the border of the drift lies within the tropic of that hemisphere. But as the *thermal* equator lies from two to three degrees to the north of the *geographical* equator, the entire zone of the trade-winds, and of the Equatorial Current propelled by them, is wider on the northern than on the southern side of the latter; and while the northerly trade often reaches 30° N. in July, and rarely extends south in January within 2° or 3° of the geographical equator, the southerly trade does not extend farther than 25° S. in January, and generally crosses the equator in July, even extending occasionally as far as 5° N. As between the northerly and southerly trades there is a region of "equatorial calms," so there is a corresponding interval between the northern and southern divisions of the Equatorial Current; and in this interval there is a counter-current (resembling the "back-water" often to be noticed in a stream that is flowing rapidly past some obstacle, such as a vessel at anchor, or a projecting angle of a river-bank), that runs eastwards, sometimes with considerable velocity, towards the Bight of Biafra, which may be considered the "head-water" of the Equatorial Current. From the recent observations of Capt. Nares in the "Challenger," it appears that the Equatorial Current, like other drift-currents, is very shallow, its depth being not much greater than 50 fathoms. He estimates its rate at the surface to be about 0·75 miles per hour, or 18 miles per day, whilst at 50 fathoms it only moves at about half that rate.[1] Its surface temperature generally ranges between 75° and 80°; but the thermometer falls to 60° at a depth of little more than 100 fathoms,—the temperature of this belt of water, as will be hereafter shown, being kept down by the continual rising of polar water from below.

The Equatorial Current passes directly across the Atlantic towards the chain of the Antilles and the coast of South America; and as not only the whole of the northern division, but a considerable part of the southern, strikes the American coast-line to the north of the salient angle of Cape St Roque (about 5° S. lat.), the portion of the current which is deflected into the northern hemisphere is much greater than that which is turned to the southward. It is a general fact, that where a current encounters any partial obstruction,—such as a coast-line meeting it obliquely, a narrowing of its channel, the lateral pressure of another current, or even that of a mass of stationary water,—its velocity increases; and so the portion of the Equatorial Current that is pressed to the northward by the coast-line between Cape St Roque and the mouth of the Orinoco (known in the first part of its course as the *Cape St Roque Current*, and afterwards as the *Guiana Current*) acquires a greatly augmented rate, running ordinarily at the rate of from 30 to 50 miles, and occasionally at a rate of 80 miles, in the 24 hours. Entering the Caribbean Sea, it is reinforced by the portion of the Equatorial Current which flows in between the Lesser Antilles; and it then passes westwards along the northern coast of South America, until it is deflected northwards by the coast-line of Central America, and driven between the peninsula of Yucatan and the western extremity of Cuba into the Gulf of Mexico, at the rate of from 30 to 60 miles per day. A portion of it passes direct to the N.E. along the northern shore of Cuba; but by far the larger part sweeps round the gulf, following the course of its coast-line, and approaches the coast of Cuba from the N.W. as a broad deep stream of no great velocity, seldom running at more than 30 miles per day. The reunited current, being met by the Equatorial Current from the outside, which is pressing to the west along the north coast of Cuba and between the Bahama isles, is deflected northwards through the passage termed the Florida Channel, which is bounded on the one side by the southern extremity of the peninsula of Florida, and on the other by the coast of Cuba and the Bahamas. The rate of movement of the powerful current that flows through this channel, henceforth known as the *Gulf Stream*, is considerably augmented in its narrowest part, which is also its shallowest; but although its velocity sometimes reaches 4 (nautical) miles per hour, or even more, its *average* rate through the whole year may be confidently stated at not more than 2 miles per hour, or 48 miles per day.[2]

The Gulf Stream current, however, does not by any means occupy the whole of the sectional area of the Florida Channel; for it is separated from the American coast by a band of cold water, which occupies about three-eighths of its total breadth of 40 miles, and which also dips under the outflowing current. The movement of the cold superficial band is perceptibly inwards, and that of the cold under-stratum is presumably so; and it is the opinion of the American surveyors that the depth of the warm outward current is not more than one-third of that of the channel through which it flows. It is probable that the rate of movement decreases from the surface downwards; but upon this point we have as yet no certain information. The meaning of the cold inflow will hereafter become apparent.

The course taken by the Gulf Stream in the first instance is nearly parallel to the line of the United States coast, from which it is everywhere separated by a band of cold water,—the boundary line between the two being so distinct as to be known as the "cold wall." It does not show for some time any great disposition to spread itself out laterally, though a division into alternate bands of warmer and colder water, the cause of which seems to lie in the contour of the bottom of the Florida Channel, becomes perceptible before it reaches Charleston, and is very marked off Cape Hatteras. The Stream there presents the form of a fan, its three warm bands spreading out over the Atlantic surface to an aggregate breadth of 167 miles,

[1] Mr Laughton, however, states the average velocity to be between 20 and 30 miles per day.

[2] This statement, which is much lower than that adopted by most writers on the Gulf Stream, is based on the entire aggregate of observations collected by the Meteorological Department, which further show that, for six months of the year, the monthly mean averages only 1·4 miles per hour, or 34 miles per day, whilst for the other six months it only averages 2½ miles an hour, or 60 miles per day.

whilst two cold bands of an aggregate breadth of 52 miles are interposed between them. The innermost warm band is the one which exhibits the highest temperature and greatest rate of flow, its velocity being greatest where it is pressed on laterally by the Arctic Current, so that a rate of 4 miles per hour is occasionally observed. Capt. Nares estimates the depth of the Stream in this part of its course at about 100 fathoms, and its rate of flow in the line of most rapid movement at 3 miles per hour. The outermost band, on the other hand, graduates insensibly, both as to temperature and rate of movement, into the general surface-water of the Atlantic. It is when passing Sandy Hook that the Gulf Stream takes its decided turn eastwards,—this change in its direction being partly due to the eastward bend of the United States coast-line, and partly to the *excess of easterly momentum* which it brings from the lower latitude in which it issued from the Florida Channel. Its general rate of flow past Nantucket seems not to exceed 1 mile per hour, and to be frequently less; but several degrees to the eastward of this, the current has been found occasionally running at the rate of 4 miles an hour,—this acceleration being probably due to the lateral pressure of the *Arctic Current*, which, during the early months of the year, is driven southwards at the rate of 10 or 12 miles per day by the N. and N.W. winds then prevailing along the coast of Labrador, and which, turning westwards round the south of Newfoundland, keeps close to the coast of the United States (being left behind in the rotation of the earth, in consequence of its *deficiency* of easterly momentum), and follows it southwards, everywhere separating it from the Gulf Stream.

By the gradual thinning-out and expansion of the Gulf Stream after passing the Banks of Newfoundland, by the progressive reduction of its rate of movement, and by the loss of that excess of temperature which previously distinguished it, as well as of its peculiar blue colour (which probably depends on its holding in suspension the finest particles of the river-silt brought down by the Mississippi), this remarkable current so far loses all its special attributes, as to be no longer recognisable to the east of the meridian of 30° W. long.,—there degenerating into the general easterly drift of that region of the Atlantic which is kept up by the prevalence of westerly winds, sometimes called "anti-trades." Where the Florida Current or true Gulf Stream can last be distinctly recognised, it forms a stratum not more than 50 fathoms in thickness; and it is there flowing *almost due east*, at a rate which would require about 100 days to bring it to the Land's End. The only valid evidence of the extension of any part of it to the western shores of Europe (the amelioration of their temperature being otherwise accounted for, while the transport of trunks of trees, drift-timber, fruits, shells, &c., to the Western Hebrides, the Orkney, Shetland, and Faroe islands, and the coast of Norway, may be fairly set down to the surface-drift sustained by the prevalence of S.W. winds) is afforded by the variable current known as *Rennell's*, which, flowing eastwards into the southern part of the Bay of Biscay, is deflected in a N.W. direction by the trend of its coast-line, so as to cross the British Channel towards the Scilly Islands, whence it passes to the S.W. coast of Ireland, its strength mainly depending on the continued prevalence of the westerly anti-trades. (See Plate I.)

Of the whole mass of water, on the other hand, that is brought into the mid-Atlantic by the Gulf Stream, it may be stated with confidence that the larger proportion turns southward to the east of the Azores, and helps to form the *North African Current*; the other tributary of which may be considered as originating as far north as Cape Finisterre, under the influence of the northerly winds which prevail along the coast of Portugal. As this current flows past the entrance to the Strait of Gibraltar, a part of it, forming what is known as the *Gibraltar Current*, is drawn in to keep up the level of the Mediterranean, which would otherwise be reduced by the excess of evaporation from its surface; but the greater part keeps its course southwards along the Marocco coast, reinforcing the south-flowing extension of the Gulf Stream. On arriving at the border of the northerly trade, the North African Current divides into two parts,—the western division being at once carried into the course of the equatorial drift, whilst the eastern, which may be considered as essentially an indraught or supply current, follows the African coast-line, and turns eastward into the Gulf of Guinea, forming the *Guinea Current*, which, coalescing with the eastward "back-water" already mentioned, flows pretty constantly, sometimes with considerable rapidity, towards the Bight of Biafra. There it meets the *South African Current*, which forms the other great feeder of the Equatorial Current; and the circulation thus completed may be considered as recommencing from this "head-water." The large area of comparatively still water which lies in the interior of this North Atlantic circulation is called the *Sargasso Sea*,—a corruption of the name (Mar de Sargaço) which it received from Columbus and the early Spanish navigators, on account of the quantity of sea-weed that floats on its surface. The boundaries of this area, which is of an irregularly elliptical shape, and nearly equals that of Continental Europe, are somewhat variable; but it may be considered to lie between the parallels of 20° and 35° N., and between the meridians of 30° and 60° W. Into it is collected a large proportion of the drift or wreck which floats about the North Atlantic.

Proceeding now to the South Atlantic, we meet with a circulation of the same kind, uncomplicated by any embaying of the Equatorial Current. The smaller division of this current which strikes the coast of South America to the south of Cape St Roque flows along the coast of Brazil at the rate of from 12 to 20 miles a day, forming the *Brazil Current*, which, however, is separated from the land by an intervening band of lower temperature, that has, during the winter months, a distinct flow towards the equator. The Brazil Current can be traced southwards, by its temperature rather than by its movement, as far as the estuary of the La Plata, before reaching which, however, a great part of it takes an easterly direction, and crosses the Atlantic towards the Cape of Good Hope, forming what is known as the *Southern Connecting Current*. The easterly movement of this current seems to be partly due to the westerly anti-trades, and partly to the excess of easterly momentum which is retained by the Brazil Current in its southward course from Cape St Roque; whilst it partly depends also on the junction of an Antarctic current that flows N.E. from Cape Horn, meeting the Brazil Current off the estuary of La Plata, just as the Arctic Current meets the Gulf Stream off Newfoundland,—dense fogs being produced, in the one case as in the other, through the precipitation of the vapour overlying the Equatorial Current, by the colder air that overlies the Polar. On meeting the coast of South Africa, the Southern Connecting Current turns northwards, and runs towards the Bight of Biafra, forming the *South African Current*, the movement of which is partly sustained by the southerly winds which prevail along that coast, but is partly attributable to the indraught set up to supply the efflux of the Equatorial Current. In its passage thither, however, the part of it most distant from the land is draughted westwards by the southern trade, forming the most southerly portion of the equatorial drift. Between this and the Southern Connecting Current is a central space, lying between the

parallels of 20° and 30° S., and the meridians of 0° and 25° W., over which there are no regular currents; and to this the name Sargasso Sea is sometimes applied by analogy, although its surface has no covering of sea-weed. (See Plate I.)

Temperature of the Atlantic.—The distribution of surface temperature over the area of the Atlantic has now been made out with considerable accuracy; and it corresponds closely with what has been already stated as the course of the surface currents. There is, of course, a seasonal change, alike in its northern and in its southern division, this change being more and more marked as we recede from the equator. Following the course of the mean annual isotherms, however, we find that they cross the South Atlantic at nearly regular intervals, in an east and west direction, the principal departure from that direction being shown at their western end in the bend they take towards the south under the influence of the warm Brazil Current, and at their eastern in the still stronger bend they take towards the north under the influence of the cold South African Current, which reduces to about 75° the temperature of the southern equatorial that flows alongside the Guinea Current, whose temperature is 82°. In the North Atlantic, however, the influence of the movement of oceanic water on the surface-temperature is very much more marked. The annual isotherms, which cross the Sargasso Sea with nearly regular parallelism, and on the African side tend somewhat to the south, where they meet the colder water of the North African Current, show a strong northward bend on the American side, along the early course of the Gulf Stream; but as its excess of temperature above that of the Atlantic generally diminishes as we trace it towards the Banks of Newfoundland, this northward deflection progressively becomes less. The marked contrast in temperature which is often there exhibited between two contiguous bands of water,—a thermometer hanging from a ship's bow showing a temperature of 70°, whilst another hanging from the stern shows only 40°,—is due not so much to the elevation produced by the Gulf Stream as to the depression produced by the Arctic Current. This depression manifests itself in the southward bend given, on the American side, alike to the summer and the winter isotherms (see Plate), beyond the summer isotherm of 70° and the winter isotherm of 60°, which may be considered as having nearly their normal position; whilst the northward tendency of these same isotherms on the European side not less conspicuously indicates a flow of warm water towards the western coasts of the British Isles, Norway, and even Iceland and Spitzbergen. It has been customary to regard this flow as an extension of the Gulf Stream; but if that term be limited (as it ought) to the current that issues from the Gulf of Mexico through the Florida Channel, the hypothesis is found to be untenable so soon as the thermal phenomena of that current are carefully examined. For, in the first place, the popular idea that the Gulf Stream retains its high temperature with little diminution during its passage first northwards and then eastwards is clearly disproved by observation, as is shown by the following table of average temperatures taken at different seasons in the warmest of its bands:—

	Latitude.	Winter.	Spring.	Summer.	Autumn.
Florida Channel	25° N.	77°	78°	83°	82°
Off Charlestown	33 N.	75	77	82	81
Off Cape Hatteras	35 N.	72	73	80	76
S.E. of Nantucket Shoals	35 N.	67	68	80	72
S. of Nova Scotia	35 N.	62	67	78	69

From this it appears that, while the high surface-temperature with which the Gulf Stream leaves the Florida Channel is retained in summer with only 5° reduction as far as Nova Scotia, there is a reduction of 5° in winter during its northward passage to Cape Hatteras, and a further reduction of no less than 10° during its eastward passage from Cape Hatteras to Nova Scotia, making a total reduction of 15°. In spring, again, there is a total reduction of 11°, and in autumn of 13°; and in both cases the reduction during the *eastward* flow under the parallel of 35° N. is greater than the reduction in the *northward* flow from 25° N. to 35° N. The explanation of this is plainly to be found in the fact that in the early part of the course of the Gulf Stream its superheated stratum is a thick one, so that when its superficial film is cooled down by a superincumbent atmosphere of lower temperature, it is replaced by the uprising of a deeper stratum having nearly its original temperature. But as the stream spreads out superficially, its superheated stratum becomes proportionally thinner, and will consequently be more and more rapidly cooled down by the superincumbent atmosphere. Even supposing, therefore, that it were not subjected to any special cooling influence, it appears certain that, as the rate of the current slackens and its depth diminishes, the cooling process must continue at an increased rate, so as to bring down the surface-temperature of the stream to the normal isotherm of the locality, long before it could reach the shores of Europe. But it has been shown that when it passes Newfoundland the Gulf Stream *is* subjected to a special cooling influence—that of the Labrador Current with its fleet of icebergs, which melt away when borne into it; and this produces such an immediate reduction of its surface-temperature, that it thenceforth shows very little excess, although its sub-surface stratum still appears to be warmer than that of the ocean through which it flows.

But, further, the Gulf Stream, where it is last recognisable as a current, is flowing due east, and its southern portion turns first south-east and then south; whilst, on the other hand, the course of the isothermal lines (see Plate) clearly shows that the flow of warm water which carries them northward spreads across the whole breadth of the Atlantic, from the British Isles to Labrador, even extending up to the west of north into Buffin's Bay. When we contrast this immense body of north-moving water with the thinned-out film of what is by comparison a mere rivulet, it becomes obvious (1) that its northward flow cannot be attributable to the *vis a tergo* of the Florida Current, whilst (2) its convection of heat to the Arctic Sea cannot be accounted for by any amount of excess of temperature that is limited to a small depth, since the temperature of such a stratum, moving north-east at a rate of (at most) 4 or 5 miles per day, must soon be brought down to that of the atmosphere above it.

Influenced by these considerations, several eminent hydrographers, both British and American, have been disposed to deny, not only that the temperature of the North Atlantic is modified in any considerable degree by the true Gulf Stream, but that any other agency than that of warm S.W. winds is concerned in producing the climatic amelioration popularly attributed to it. They maintained, in fact, that the surface-temperature of the North Atlantic and Arctic Seas *follows* that of the superincumbent air,—the atmospheric temperature not being in any degree raised by that of warmer water beneath. This doctrine, however, is found to be inconsistent with the results of careful comparisons recently instituted between marine and atmospheric temperatures along the western coasts of Scotland, the Orkney, Shetland, and Faroe Islands, and especially with those obtained along the western coast of Norway. For it is found that during the winter months there is a constant *excess* of sea-temperature above that of the air, averaging

6°·2 Fahr. along the western coast of Scotland and its islands, and rising to 14°·5 at Fruholm near the North Cape. And it is also a very significant fact (ascertained by the careful inquiries of Mr Buchan), that while the *summer* isotherms cross the British Islands nearly east and west (the temperature diminishing pretty regularly from south to north), the *winter* isotherms traverse them nearly north and south (the temperature diminishing from west to east); whilst in Ireland the isotherms seem to envelop the islands in their folds, which increase in warmth from the centre of the island to its sea-board. So in Norway the isothermal lines run parallel to the coast-line, and this alike in summer and in winter,—the temperature falling in winter, and rising in summer, with the increase of distance from the sea. Nothing could prove more conclusively than such facts as these (taken in connection with the absence of ice in the harbours of Norway, even as far north as Hammerfest, through the whole winter) the dependence of the mild winter climate of the north-western coasts of Europe upon the proximity of a sea which is warmer than the superincumbent atmosphere; and we have now to inquire how this great N.E. movement of a stratum of warm water sufficiently thick to retain a surface-temperature considerably higher than that of the air above it is to be accounted for.

The solution of the problem seems to be afforded by the doctrine of a *General Oceanic Circulation*, sustained by opposition of temperature only, which was first distinctly propounded in 1845 by Professor Lenz of St Petersburg, on the basis of observations made by him during the second voyage of Kotzebue (1825-1828). Others had been previously led to surmise that "Polar Currents" flow along the floors of the great oceans, even as far as the equator, balancing the superficial counter-currents which are observable in the opposite direction. But Lenz was led to conclude that the whole of the deeper portion of the great ocean-basins in communication with the polar areas is occupied by polar water, which is constantly, though slowly, flowing towards the equator; whilst conversely the whole upper stratum of equatorial water is as constantly, though slowly, flowing towards one or both of the poles. And he particularly dwelt on the existence of a belt of water under the equator, colder than that which lies either north or south of it, as an evidence that polar water is there continually rising from beneath towards the surface,—a phenomenon which, he considered, admits of no other explanation. He further adduced the low salinity of equatorial water (previously noticed by Humboldt, and confirmed by his own observations), compared with that of tropical water, as evidence that the equatorial water of the surface is derived from the polar underflow. And he attributed the maintenance of this circulation to the continually renewed disturbance of equilibrium between the polar and equatorial columns,—the greater lateral (because downward) pressure of the former[1] causing a *bottom outflow* of polar water in the direction of the latter, whilst the reduction of level thus occasioned will produce a *surface indraught* from the warmer towards the colder areas.

The doctrine of Lenz, so far from meeting with the general acceptance to which it had a fair claim,—alike on theoretical grounds and from its accordance with the facts ascertained by careful observation,—seems to have been put aside and forgotten, a preference being given to the doctrine of the prevalence of a uniform deep-sea temperature of 39° which was supposed to be established by the thermometric observations made in the voyages of D'Urville and Sir James Ross. No such precaution was taken, however, in these observations as that to which Lenz had recourse, to obviate the effects of the tremendous pressure (1 ton per square inch for every 800 fathoms of depth) to which deep-sea thermometers are exposed; and it is now certain that the temperatures at great depths recorded by D'Urville and Ross were several degrees too high.

It was in entire ignorance of the doctrine of Lenz, and under the influence of that of D'Urville and Ross, which had been stamped with the great weight of Sir John Herschel's weight of authority,[2] that Dr Carpenter commenced in 1868 (in concert with Professor Wyville Thomson) a course of inquiry into the thermal condition of the deep sea, which at once convinced him of the fallacy of the uniform 39° doctrine, and led him to conclusions essentially accordant with those of Lenz. For in the channel of from 500 to 600 fathoms' depth between the north of Scotland and the Faroe Islands, they found the deeper half to be occupied by a stratum of glacial water, whose temperature ranged downwards from 32° to 29°·5; whilst the upper half was occupied by a stratum warmer than the normal temperature of the latitudes. This phenomenon was interpreted by Carpenter as indicating a deep glacial flow from N.E. to S.W., and a warm upper flow from S.W. to N.E.; and finding that to the west of this channel, on the border of the deep Atlantic basin, the excess of warmth extended to a depth of more than 500 fathoms, he came to the conclusion that the north-moving stratum which brought it could not be an extension of the true Gulf Stream, but must be urged on by some much more general force. A series of temperature-soundings taken along the west of Ireland, the Bay of Biscay, and the coast of Portugal, confirmed him in this view, by showing that the division between an upper warm stratum and a cold under-stratum exists in the North Atlantic at a depth of from 700 to 900 fathoms, the whole mass of water below this having either flowed into the basin from the polar area, or having had its temperature brought down to from 39° to 36°·5 by mixture with the polar inflow. And this conclusion was confirmed by the result of temperature-soundings taken at corresponding depths and under the same parallels of latitude in the Mediterranean; for as they showed a uniform temperature of from 54° to 56°, from beneath the stratum of 100 fathoms that was superheated by direct insolation, to the very bottom, it became clear that depth *per se* could have no effect in reducing the bottom-temperature; and that the cause of the excess of temperature in the mass of water occupying the Mediterranean basin above that of Atlantic water at the same depths, lies in the seclusion of the former from the polar underflow which brings down the deep temperature of the latter. This conclusion having received marked confirmation from temperature-soundings taken in the Eastern seas, was put forward by Carpenter as justifying the doctrine of a *vertical* oceanic circulation sustained by opposition of temperature only, quite independent of and distinct from the *horizontal* circulation produced by wind,—which doctrine he expressed in terms closely corresponding with those that had been used by Lenz. And the collection of data for the establishment or confutation of this doctrine was one of the objects of the "Challenger" expedition, which has already made, in the determination of the thermal stratification of the Atlantic between 38° N. lat. and 38° S. lat., what may be fairly characterised as the grandest single contribution ever yet made to terrestrial physics.

The following are the most important of the facts thus

[1] It must be borne in mind that sea water does not expand like fresh water in cooling below 39°·2, but continues to contract down to its freezing point, which lies between 27° and 25° Fahr., according as it is still or agitated.

[2] See his *Physical Geography of the Globe*, originally published in the eighth edition of this *Encyclopædia*.

established:—Of the water which fills the deep trough of the North Atlantic (fig. 1) between Teneriffe (lat. 28½° N.) and St Thomas (lat. 18½° N.), divided by the "Dolphin rise" into an eastern and western basin, by far the larger

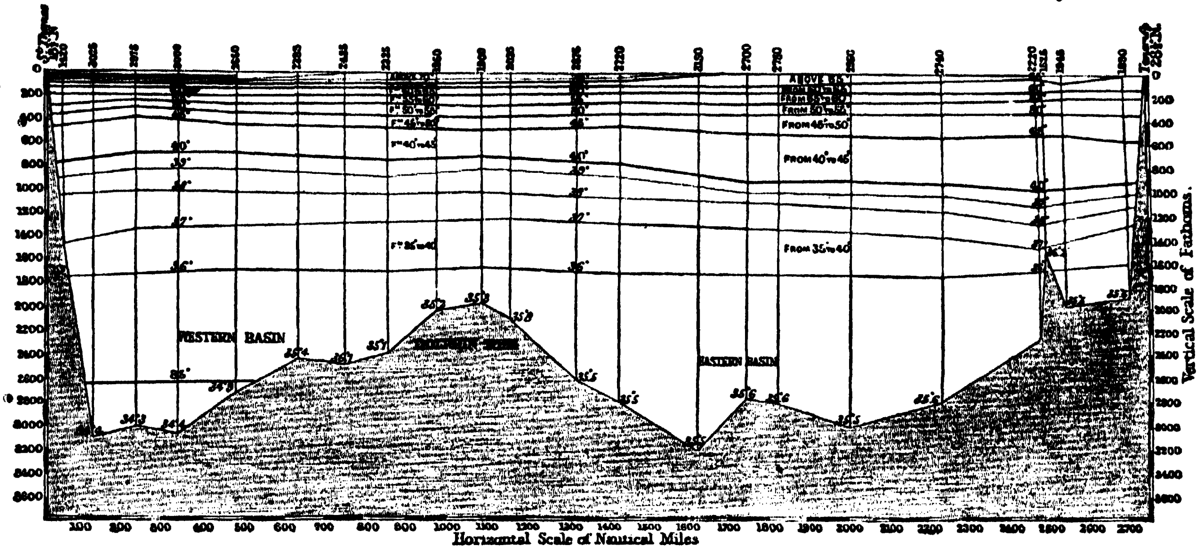

FIG. 1.—Section of North Atlantic Ocean between St Thomas and Teneriffe.

ıass has a temperature ranging from 40° downwards, in ıe eastern basin, to a bottom-temperature of 35½°, whilst ı the western basin—apparently under the influence of ıe Antarctic underflow—the bottom-temperature sinks to 4°·4. A tolerably regular descent is shown in this sec-on, from a surface-temperature rising near St Thomas to 5°, to the bathymetrical isotherm of 45°, which lies be-veen 400 and 600 fathoms' depth; there is then a stratum ɜtween 45° and 40°, of which the thickness varies from ɔout 250 to 450 fathoms, the isotherm of 40° lying at ɜtween 750 and 1000 fathoms' depth, while below this, ɔwn to the bottom at between 2000 and 3000 fathoms, ıe further reduction to 34°·4 is very gradual.

The same general condition prevails in the South tlantic (fig. 2), between Abrolhos Island (lat. 18° S.) on .e coast of Brazil, and the Cape of Good Hope (lat. 34½° S.), this trough also being divided into two basins by the elevation of the bottom which culminates in the island of Tristan da Cunha. The temperature of the water that occupies it, however, is lower through its whole vertical range than that of the North Atlantic. The stratification is nearly uniform from the surface downwards to the isotherm of 40°, which lies at from 300 to 450 fathoms' depth, the isotherms of 39° and 38° also lying within about 500 fathoms; there is then a slower reduction down to the isotherm of 35°, which lies between 1400 and 1800 fathoms; while the whole sea-bed is covered by a stratum of about 600 fathoms' thickness, whose temperature ranges downwards from 35° to 33°. The whole of this deepest stratum is colder than any water that is found in the corresponding portion of the North Atlantic, except near St Thomas.

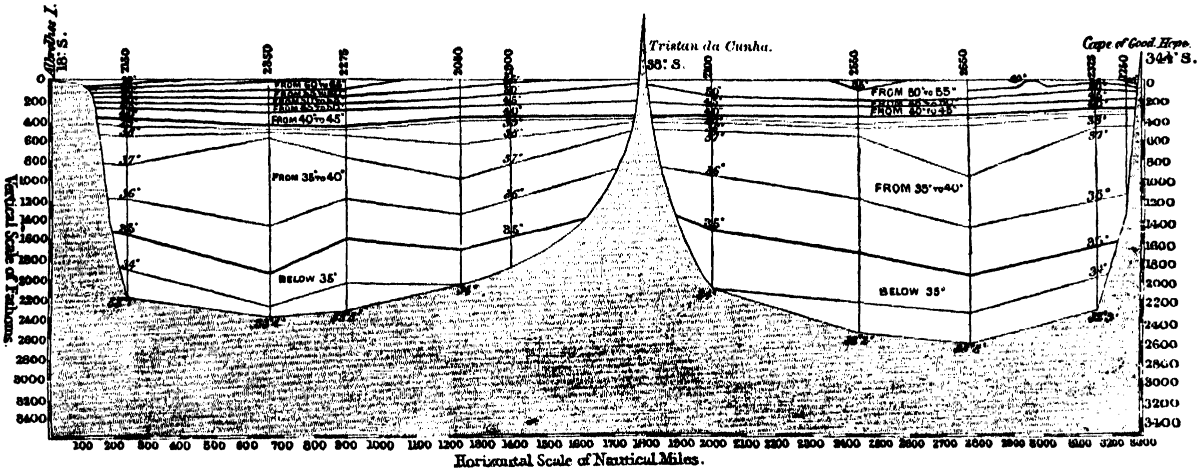

FIG. 2.—Section of South Atlantic.

[t is not a little remarkable that the sub-surface stratum water, having a temperature above 40°, is thinner under ı equator than it is in any other part of the Atlantic m the Faroe Islands to the Cape of Good Hope. Not-ɦhstanding the rise of the surface-temperature to 76°–80°, : thermometer descends in the first 300 fathoms more ɪidly than anywhere else; so that polar water is met ɦh, as shown in fig. 3, at a much less depth than in the North Atlantic (fig. 1), and 100 fathoms nearer to the surface than even in the colder South Atlantic (fig. 2); whilst the temperature of the bottom is but little above 32°. Thus the influence of the polar underflow is more pronounced under the equator than it is elsewhere; as is distinctly seen in the section shown in fig. 4, which is taken in a north and south direction so as to exhibit the relation of the thermal stratification of the North to that

of the South Atlantic, and of both to that of the equatorial

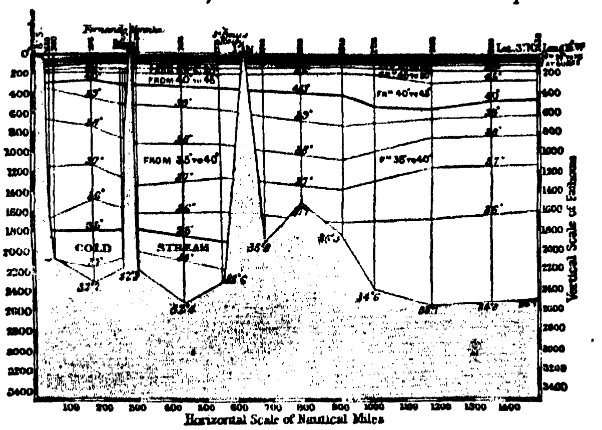

FIG. 3.—Section of Equatorial Atlantic.

belt. The isotherm of 40°, which in lat. 22° N. lies at a depth of about 700 fathoms, gradually rises as the equator is approached; and it is between the equator and 7° S., where the surface-temperature rises to nearly 80°, that cold water is soonest reached,—the isotherm of 40° rising to within 300 fathoms of the surface, while that of 55°, which in lat. 38° N. lies at nearly 400 fathoms' depth, and in lat. 22° N. at about 250 fathoms, actually comes up under the equator within 100 fathoms of the surface. At the same time, while the bottom-temperature under the equator is the lowest anywhere met with, namely, 32°·4,[1] the thickness of the stratum beneath the isotherm of 35° is not less than 600 fathoms. In passing southwards, the superficial isotherms are observed to separate again from each other, partly by the reduction of the surface-temperature, and partly by the descent of the isotherm of 40° to a depth of something less than 400 fathoms, which it keeps with little reduction as far south as the Cape of Good Hope. The significance of these facts becomes more remarkable, when we consider that if a portion of the oceanic area under the equator were to be secluded, like the Mediterranean or the

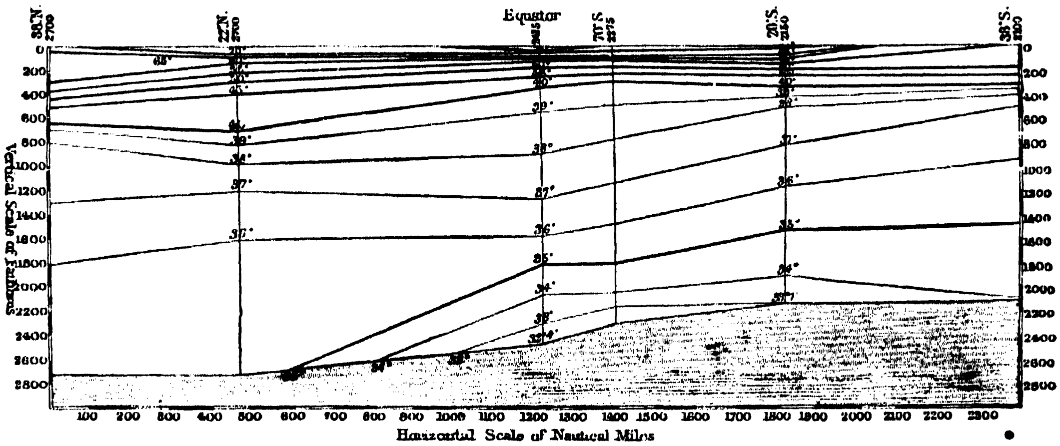

FIG. 4.—Section of Mid-Atlantic, taken nearly north and south.

Red Sea, from all but local influences, the temperature of its water from the sub-surface stratum downwards to the bottom—whatever its depth—would be its *isocheimal* or mean winter-temperature, which, in the equatorial zone, would be certainly not below 75°.

Nothing, Dr Carpenter contends, could more conclusively support the general doctrine of a *Vertical Oceanic Circulation* sustained by opposition of temperature, than the precise conformity of the facts thus determined by observation to the predictions which his confidence in the theory had led him to put forth. These predictions were essentially as follows:—

"1. That instead of the local depressions of bottom-temperature imputed by previous writers to polar currents, the temperature of every part of the deep sea-bed in communication with either of the polar areas would be not many degrees above that of the polar areas themselves.

"2. That this general depression of bottom-temperature would be found to depend, not upon such a shallow glacial stream as might be maintained to be a return from the polar areas of water propelled towards them by wind-currents, but upon a creeping flow of the whole under-stratum, having a thickness of from 1000 to 2000 fathoms.

"3. That as the depression of bottom-temperature in any part of the general oceanic basin would be proportional to the freedom of communication between its deeper portion and that of one or other of the polar areas, the bottom-temperature of the South Atlantic would probably range downwards to 32°, while that of the North Atlantic would not be below 35°, except where it first receives the Arctic flow, or comes under the influence of the Antarctic underflow, which would very probably extend itself to the north of the equator.

"4. That as the Arctic and Antarctic underflows must meet at or near the equator, whilst the surface-stratum is there continually being draughted off thence towards either pole, there would be a continual ascent of glacial water under the line, showing itself by a nearer approach of cold water to the surface in the *inter*-tropical than in the *extra*-tropical zone."

It was further pointed out by Lenz, and more recently (in ignorance of his doctrine) by Carpenter, that additional evidence of such ascent is furnished by the low salinity of the surface-water of the equatorial belt corresponding with that of polar water. For, as was originally observed by Humboldt, then by Lenz himself, and subsequently by many other voyagers, the specific gravity of the surface-water of the Atlantic gradually increases as either tropic is approached from the polar side of its own hemisphere, reaches its maximum a little nearer the equator, and then rapidly diminishes, coming down under the equator to the standard of polar water. Thus a mean of eight observations taken in the "Challenger" expedition between Bermuda (32° N.) and St Thomas (18½° N.) gave 1027·2 as the sp. gr. of *surface-water*, whilst a mean of seventeen observations between the Cape Verd Islands (16½° N.) and Bahia (13° S.) gave a sp. gr. of only 1026·3. Now, since between St Thomas and Bermuda the eight "Challenger" observations of *bottom* (polar) water gave a mean sp. gr. of 1026·3, whilst between Cape Verd and Bahia the mean sp. gr. of the bottom-water was even slightly lower (the results being

[1] That the bottom-temperature beneath the equator was lower than any that was met with in the South Atlantic, is attributable to the circumstance that, in consequence of unfavourable weather, the temperature-soundings were taken at intervals too wide to detect the deep channel through which the *coldest* Antarctic water doubtless flowed towards the equator.

in all cases expressed according to a common standard of temperature), such a close conformity subsists between the salinity of the equatorial water of the surface and that of the polar waters of the bottom, as can scarcely be accounted for in any other way than by the continual and tolerably rapid ascent of the latter.

Another indication of this ascent is given by the moderation of the surface-temperature of oceanic water, even under the equator. If there were no ascent of colder water from beneath, there seems no reason why the constant powerful insolation to which equatorial water is subjected should not raise the temperature of its surface to the highest possible elevation. The limit to that elevation, which is obviously set by the cooling influence of evaporation, is probably that which is met with in the Red Sea, where the monthly average for August rises to 86½°, and for September to 88°, whilst the maxima rise much higher, temperatures of 100°, 106°, 100°, and 96° having been noted on four consecutive days. Moreover, along the Guinea Coast, and especially in the Bight of Biafra, the surface-temperature is stated to range as high as 90°. But in these cases there is no reduction of surface-temperature by the upward movement of polar water; for this is altogether excluded from the Red Sea by the shallowness of the Strait of Babelmandeb, whilst the depth of the bottom along the Guinea Coast is too small to allow of its being overflowed by the glacial stratum. Now, over the deeper parts of the equatorial Atlantic the surface-temperature usually ranges between 75° and 80°; and this is its ordinary range in the Mediterranean during the months of August and September. That the temperature of an equatorial ocean should be thus kept down to that of a sea of which the greater part lies between the parallels of 40° and 35°, can scarcely be accounted for in any other way than by the continual uprising of polar waters from beneath.

The same principle, once admitted, fully accounts for that amelioration of the cold of north-western Europe, which (as already shown) cannot be fairly attributed to the Florida Current or true Gulf Stream. For it is obvious that a continual efflux of the lower stratum from the polar areas towards the equatorial must involve a continual indraught of the upper stratum towards the polar areas; and this indraught will be much more marked in the Northern than in the Southern Atlantic, on account of the progressive narrowing of the former, whilst the latter progressively widens out. Of such a slow northerly set of a stratum of water, extending downwards to a depth of at least 600 fathoms, we have evidence in a comparison of the temperature-soundings taken in the "Porcupine" expedi-

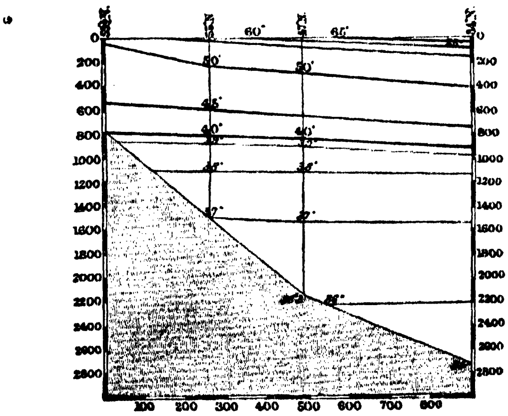

FIG. 5.—Section of North Atlantic, taken nearly north and south.

tions of 1869 and 1870, between the coast of Portugal (34° N.) and the Faroe Islands (59½° N.), from which the section fig. 5 has been worked out. For it is there seen that, although the surface-temperature is reduced by the thinning-out of the superficial stratum, there is but a slight change in the position of the bathymetrical isotherms of 45° and 40°; so that there is an obvious continuity of a stratum of many hundred fathoms' thickness between these two points, notwithstanding their separation by 25½° of latitude. The contrast between the position of the isotherm of 40° at 800 fathoms' depth off the Faroes, and its position at less than 300 fathoms' depth under the equator, is most remarkable. We have seen that the isocheimal in the latter area would not be below 75°, and yet we find water colder than 40° lying at within 300 fathoms of the surface; whilst, on the other hand, the normal isocheimal at 59½° N. would certainly be below 40° (probably no more than 35°), and yet we find water above 43° extending downwards to 600 fathoms, and water above 40° to 800 fathoms. Thus the vertical oceanic circulation carries a vast mass of water which is *below* the normal off the coast of Portugal, into a region where it is *above* the normal, with very little loss of heat by the way, except in its surface-film; and a little consideration will show that such a movement must be much more effectual as a *heater* than a corresponding movement of a thin stratum of much warmer water. For the latter, when it passes beneath an atmosphere much colder than itself, will soon be brought down to a like standard, not having warmer water from below to take its place when it has been cooled down; whilst in the former, each surface-layer, when cooled below the temperature of the warmer stratum beneath, will sink and be replaced by it. Now since the true Gulf Stream, when we last know it, has been so thinned out that it could not long retain any excess of temperature, it seems inconceivable that it should exert any decided effect on the temperature of the Faroes and the coast of Norway, unless (as supposed by Dr Petermann and Professor Wyville Thomson) its thickness undergoes an increase from less than 100 fathoms to 600. But since the course of Dr Petermann's isotherms shows that the northward flow extends across the whole breadth of the Atlantic between Newfoundland and the British Isles—a distance of about 2000 miles—we are required to believe that a rivulet (for such it is by comparison) of 60 miles' breadth and 100 fathoms' depth (see section, fig. 5), of which the greater part turns southwards round the Azores, and of which the remainder is flowing due east when we last recognise it, is able to impart a northerly movement to a stratum of 2000 miles in breadth, and at least 600 fathoms' depth. On the other hand, the eastward set of this stratum, considered as a northward *indraught* into the polar area, is readily accounted for by the excess of easterly momentum which it derives from the earth's rotation, this being only half as rapid in lat. 60° as it is under the equator; and since there is a still more rapid reduction in the rate of this rotation in yet higher latitudes, the continually increasing excess of easterly momentum will give to the northward flow a progressively stronger eastward set.

On the other hand, the deficiency of easterly momentum in the cold underflow coming from the pole towards the equator will tend to produce a lagging-behind, or *westward* set of that underflow; and this has been shown by the "Challenger" temperature-soundings to be the case,—the cold deep strata of the Western Atlantic surging upwards along the slope of the North American coast-line, as is shown in fig. 6, where we see not only the bathymetrical isotherms of 60°, 55°, and 50°, but the yet deeper isotherms of 45° and 40°, successively rising to the surface as we approach the land; while at a depth of only 83 fathoms, a temperature of 35° was encountered, which, at no great distance to the south, would only be found at a depth of 2000 fathoms. That the cold water should thus run

uphill is quite conformable to what we see in other cases, in which a heavier under-stratum has a definite set towards a slope; and whilst the existence of such a westerly set is, *ex hypothesi*, a necessary consequence of the southerly movement of the Arctic underflow, no other explanation of it has been suggested. We now see that the cold Labrador Current overlies a band of water as cold as itself; and the southward extension of this cold band, far beyond that of any definite current-movement, and its entrance into the Gulf of Mexico, through the Florida Channel, at the side of and beneath the outflowing Gulf Stream, are thus accounted for.

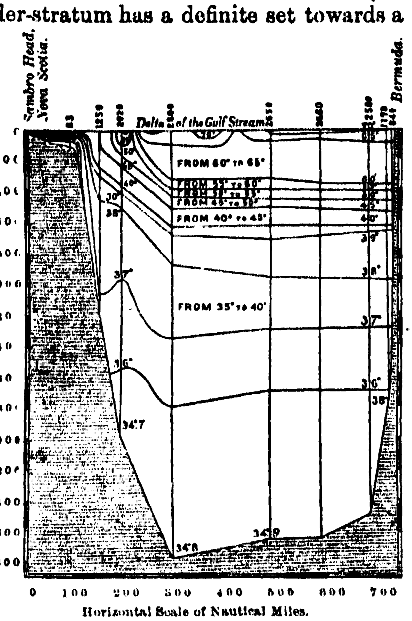

FIG. 6.—Section from Bermuda to Halifax.

The remarkable accordance of so many facts of actual observation, in the Atlantic area, with the probabilities deducible from a theory whose soundness can scarcely be disputed, seems now to justify the admission of the general (vertical) oceanic circulation sustained by opposition of temperature as an accepted doctrine of terrestrial physics.

Distribution of Organic Life.—All that will be attempted under this head will be to indicate the general conditions that seem, from recent researches, to have the greatest influence on the distribution of plants and animals through this great oceanic basin.

The distribution of marine plants seems mainly determined by light, temperature, and depth,—a further influence being exerted by the character of the shores. The diminution of light in its passage through sea-water is so rapid, that the quantity which penetrates to a depth of 250 or 300 fathoms may be regarded as almost infinitesimal; and in conformity with this we find a very rapid diminution of Algal life below the depth of 100 fathoms. The upper stratum is occupied for the most part by the larger and coarser forms of the *Fucaceæ*, or olive-green sea-weeds, whilst the more delicate *Ceramiaceæ*, or red sea-weeds, frequent deeper waters; and, as it appears from experiments made in aquaria that the latter do not flourish in full light, but grow well in shadow, it may be concluded that their preference for a moderate depth is rather for reduced light and stillness than for depth *per se*. At a depth of 150 fathoms very few ordinary sea-weeds maintain their ground; and below this we seldom find any Algæ, save the Corallines and Nullipores consolidated by calcareous deposit. The distribution of particular types over different parts of the Atlantic area appears to be mainly regulated by temperature; and this would seem to be remarkably the case with the floating *Diatomaceæ*, which, though they form green bands in the surface-water of polar seas, have not been encountered in like abundance in the Atlantic, and do not contribute largely, by the subsidence of their siliceous *loricæ*, to the composition of its bottom-deposit. Although it is the habit of the larger Algæ to grow from a base of attachment (their roots serving no other purpose, however, than that of anchorage), the enormous mass of Gulf-weed found in the Sargasso Sea seems quite independent of any such attachment. It was at one time supposed that this originally grew on the Bahama and Florida shores, and was torn thence by the powerful current of the Gulf Stream; but it seems certain that if such was its original source, the "Gulf-weed" now lives and propagates whilst freely floating on the ocean-surface, having become adapted by various modifications to its present mode of existence.

The distribution of the animals that habitually live in that upper stratum of the ocean whose degree of warmth varies with the latitude, seems mainly determined by temperature. Thus the "right whale" of Arctic seas, and its representative in the Antarctic, seems never to enter the inter-tropical area, generally keeping away from even the temperate seas, whilst, on the other hand, the sperm-whale ranges through the parts of the ocean where the "right whales" are never seen.

The distribution of fishes seems generally to follow the same rule; as does also that of floating molluscs. Thus the little *Clio* (a Pteropod mollusc), which is a principal article of the food of the "right whales" in polar seas, is rarely met with in the Atlantic, where, however, other pteropods, as *Hyalæa*, present themselves in abundance. On the other hand, the warmer parts of its area swarm with Salpa-chains, which are not frequent in higher latitudes; and the few representatives of the Nautiloid Cephalopods, that were so abundant in Cretaceous seas, are now restricted to tropical or sub-tropical areas. And the distribution of the molluscs, echinoderms, and corals, which habitually live on the bottom, seems to be determined, within certain limits at least, by temperature rather than by depth.

The bathymetrical range to which animal life of any higher type than the Rhizopodal might extend, was until recently quite unknown; but the researches initiated by Prof. Wyville Thomson and Dr Carpenter in 1868, and since prosecuted by the "Challenger" expedition, have fully established the existence of a varied and abundant fauna in ocean-depths ranging downwards to 2000 fathoms. And these researches have further established that the distribution of this fauna is mainly determined by the temperature of the sea-bed; so that whilst in the channel between the north of Scotland and the Faroes there were found at the same depths, and within a few miles of each other, two faunæ almost entirely distinct—one a boreal and the other a warmer-temperate—on sea-beds having respectively the temperatures of 30° and 43°, various types to which a low temperature is congenial are traceable continuously along the whole abyssal sea-bed that intervenes between those northern and southern polar areas within which they present themselves at or near the surface. And hence it becomes clear that, since glacial types are even now being embedded in the strata which are in process of formation beneath the equator, no inferences as to terrestrial climate can be drawn from the character of marine deposits.

One very remarkable feature which presents itself over a large proportion of the Atlantic basin is the abundance of the minute *Globigerinæ* and other Foraminifera, the accumulation of whose shells, and of their disintegrated remains, is giving rise to a calcareous deposit of unknown thickness, that corresponds in all essential particulars to Chalk. This deposit, in some parts of the North Atlantic, is replaced by an Arctic drift of fine sand, whilst in other parts there is a mixture of arenaceous and of calcareous components, such as is found in certain beds of the Cretaceous formation. Now on the surface of this deposit there have been found so many living types, especially belonging to the groups of Echinoderms, Corals, Siliceous Sponges, and Foraminifera, which closely correspond with types hitherto regarded as characteristic of the Cretaceous epoch, that the question naturally suggests itself whether

the existing are not the lineal descendants of the fossil types,—the differences they present being not greater than may be fairly attributed to the prolonged action of differences of temperature, food, pressure, &c. And when these facts are taken in connection with those previously stated as to the probable remoteness of the period when (if ever) the present sea-bed of the Atlantic was dry land, the doctrine first put forth by Prof. Wyville Thomson, that there has been a continuous formation of Globigerina-mud on the bottom of the Atlantic from the Cretaceous epoch to the present time—or, in other words, that the formation of chalk on the sea-bed of the Atlantic did not cease with the elevation of the European area, but has been going on through the whole Tertiary period,—must be admitted as (to say the least) a not improbable hypothesis. That some considerable change took place at the conclusion of the Cretaceous epoch, by which the temperature of the upper stratum was lowered, so as to be no longer compatible with the existence of the fishes and chambered cephalopods characteristic of the Cretaceous fauna, may be fairly assumed from their disappearance; but this would not so much affect the deeper part of the basin, in which those lower types that seem more capable of adapting themselves to changes in external conditions would continue to hold their ground. That the like conditions had prevailed also through long previous geological periods, may be surmised from the persistence, over various parts of the Atlantic sea-bed, of the *Apiocrinite* type, which carries us back to the Oolitic formation, and of the *Pentacrinus* type, which has come down with very little alteration from the Liassic; whilst many existing *Terebratulidæ* do not differ more from Oolitic types than the latter differ among each other. Going back still further, we find in the persistence of certain Foraminiferal types from the Carboniferous limestone to the present time, and in the character of its deep-sea beds, a strong indication that they originated in a Foraminiferal deposit, representing in all essential particulars that which is now going on; while the persistence of the *Lingula* from the early Silurian strata to the present time suggests the question whether certain oceanic areas may not have remained in the condition of deep sea throughout the whole subsequent succession of geological changes.

Bibliography.—In addition to the ordinary sources of information, the following publications may be specially referred to for recent information in regard to the physical geography of the Atlantic:—"Reports of the Deep-Sea Explorations carried on in H.M. Steam-vessels 'Lightning,' 'Porcupine,' and 'Shearwater,'" in *Proceedings of the Royal Society* for 1868, 1869, 1870, and 1872; "On the Gibraltar Current, the Gulf Stream, and the General Oceanic Circulation," in the *Journal of the Royal Geographical Society* for 1871; and "Further Inquiries on Oceanic Circulation" (containing a summary of the "Challenger" Temperature Survey of the Atlantic), in the same journal for 1874; *Currents and Surface-Temperature of the North and South Atlantic*, published by the Meteorological Committee; and *The Depths of the Sea*, by Prof. Wyville Thomson. (W.B.C.)

ATLANTIS, Atalantis, or Atlantica, an island mentioned by Plato and other classical writers, concerning the real existence of which many disputes have been raised. In the *Timæus*, Critias relates how his grandfather Critias had been told by Solon some remarkable events in early Athenian history which he had learned from the Egyptian priests at Sais, whose records went much further back than the native accounts. "The most famous of all the Athenian exploits," Solon had been told, "was the overthrow of the island Atlantis. This was a continent lying over against the pillars of Hercules, in extent greater than Libya and Asia put together, and was the passage to other islands and to another continent, of which the Mediterranean Sea was only the harbour; and within the pillars the empire of Atlantis reached to Egypt and Tyrrhenia. This mighty power was arrayed against Egypt and Hellas and all the countries bordering on the Mediterranean. Then did your city bravely, and won renown over the whole earth. For at the peril of her own existence, and when the other Hellenes had deserted her, she repelled the invader, and of her own accord gave liberty to all the nations within the pillars. A little while afterwards there was a great earthquake, and your warrior race all sank into the earth; and the great island of Atlantis also disappeared in the sea. This is the explanation of the shallows which are found in that part of the Atlantic ocean."—(Jowett's *Introduction to the Timæus*.) Such is the main substance of the principal account of the island furnished by the ancients,—an account which, if not entirely fictitious, belongs to the most nebulous region of history. The story may embody some popular legend, and the legend may have rested on certain historical circumstances; but what these were it is (as the numerous theories advanced on the subject may be held as proving) impossible now to determine.

ATLAS (Ἄτλας), in *Greek Mythology*, called sometimes a son of Japetus and the nymph Asia, or of Uranus and Gaia, and at other times traced to a different parentage, but always known as the being who supported on his shoulders the pillars on which the sky rested. He knew the depths of the sea (*Odyssey*, vii. 245), and in the first instance seems to have been a marine creation. The pillars which he supported were thought to rest in the sea, immediately beyond the most western horizon. But by the time of Herodotus (iv. 184), a mountain is suggested as best suited to hold up the heavens, and the name of Atlas is transferred to a hill in the N.W. of Africa. Then the name is traced to a king of that district, rich in flocks and herds, and owning the garden of the Hesperides. Finally, Atlas was explained as the name of a primitive astronomer. He was the father of the Pleiades and Hyades. Perseus encountered him when he searched for Medusa. Heracles took the burden of the sky from his shoulders, but cleverly contrived to replace it. Atlas bearing up the heavens is mentioned as being represented on early works of art, *e.g.*, on the chest of Cypselus (Pausan., v. 18, 1), and on the throne of Apollo at Amyclæ (Pausan., iii. 18, 7); and this subject occurs on several existing works of art.

ATLAS, a mountain-chain of Northern Africa, between the great desert of the Sahara and the Mediterranean. The range has been but partially explored, and geographers differ as to its extent, some considering it to reach from Cape Ghir on the Atlantic to Cape Bon, the north-east point of Tunis, while others include under the name the whole mountain system between Cape Nun and the greater Syrtis. In this latter sense it forms the mountain-land of the countries of Marocco, Algeria, Tunis, and Tripoli. It is composed of ranges and groups of mountains, enclosing well-watered and fertile valleys and plains, and having a general direction from W. to E. The highest peaks are supposed to attain an elevation of nearly 15,000 feet; and although none of them reach the height of perpetual snow, some of their loftiest summits are covered with snow during the greater part of the year. Mount Miltsin, 27 miles S.E. of the city of Marocco, was ascertained by Captain Washington to be 11,400 feet high. The greatest heights are in Marocco, from which point they appear to diminish in

elevation as they extend towards the E. These mountains, except the loftier summits, are, for the most part, covered with thick forests of pine, oak, cork, white poplar, wild olive, and other trees. The inferior ranges seem to be principally composed of Secondary limestone, which, at a greater elevation, is succeeded by micaceous schist and quartz-rock; and the higher chains are said to consist of granite, gneiss, mica-slate, and clay-slate. The Secondary and Tertiary formations are frequently disturbed and upraised by trap-rocks of comparatively modern date. Lead, iron, copper, antimony, sulphur, and rock-salt occur frequently; and in the Marocco portion of the range gold and silver are said to exist. In the Algerian division are mines of copper, lead, silver, and antimony. The lion, hyena, boar, and bear are common throughout the mountains. None of the rivers which take their rise in the system are of any great importance. The Tafilet is absorbed in the sands; the Tensift and Draa flowinto the Atlantic; and about five or six find their way to the Mediterranean. Dr Hooker has explored the botany of many parts of the range, and the travels of Rohlfs have added largely to our general knowledge of it.

ATMOSPHERE

ATMOSPHERE is the name applied to the invisible elastic envelope which surrounds the earth, the gaseous matter of which it is composed being usually distinguished by the name of air. Storms and weather generally, solar and terrestrial radiation, the disintegration of rocks, animal and vegetable life, twilight, and the propagation of sound, are some of the more striking phenomena which are either to a large extent or altogether dependent on the atmosphere. That air possesses weight may be shown by the simple experiment of taking a hollow globe filled with air and weighing it; then removing the contained air by means of an air-pump, and again weighing the globe, when it will be found to weigh less than at first. The difference of the two results is the weight of the air which has been removed. From Regnault's experiments, 100 cubic inches of dry air, or air containing no aqueous vapour, under a pressure of 30 English inches of mercury, and at a temperature of 60° Fahr., weigh 31·03529 grains; and since 100 cubic inches of distilled water at the same pressure and temperature weigh 25,252½ grains, it follows that air is 813·67 times lighter than water.

Air as an elastic fluid exerts pressure upon the earth or any substance on which it rests, the action of a boy's sucker and of a water-pump being familiar instances showing the pressure of the atmosphere. When air is removed from a water-pump, the water rises in the pump only to a certain height; for as soon as the water has risen to such a height that the weight of the column of water in the pump above the level of the surface of the water in the well just balances the pressure exerted by the atmosphere on the surface of the well, it ceases to rise. If the pressure of the atmosphere be increased, the water will rise higher in the pump; but if diminished, the level of the water will sink. The height to which the water rises within the pump thus varies with the pressure of the atmosphere, the height being generally about 34 feet. Since a given volume of mercury weighed *in vacuo* at a temperature of 62° Fahr. is 13·569 times heavier than the same volume of water, it follows that a column of mercury will rise *in vacuo* to a height 13·569 times less than a column of water, or about 30 inches. If we suppose, then, the height of the mercurial column to be 30 inches, which is probably near the average height of the barometer at sea-level, and its base equal to a square inch, it will contain 30 cubic inches of mercury; and since one cubic inch of mercury contains 3426·7 grains, the weight of 30 cubic inches will be nearly 14·7304 lb avoirdupois. Thus the pressure of the atmosphere is generally, at least in these latitudes, at sea-level equal to 14·7304 lb on each square inch of the earth's surface. Sir John Herschel has calculated that the total weight of an atmosphere averaging 30 inches of pressure is about 11⅝ trillions of pounds; and that, making allowance for the space occupied by the land above the sea, the mass of such an atmosphere is about $\frac{1}{1200000}$ part of that of the earth itself. This enormous pressure is exerted on the human frame in common with all objects on the earth's surface, and it is calculated that a man of the ordinary size sustains a pressure of about 14 tons; but as the pressure is exerted equally in all directions, and permeates the whole body, no inconvenience arises in consequence of it.

A pressure agreeing approximately with the average atmospheric pressure at sea-level is often used as a unit of pressure. This unit is called *an atmosphere*, and is employed in measuring pressures in steam-engines and boilers. The value of this unit which has been adopted, in the metrical system, is the pressure of 760 millimètres (29·922 Eng. inches) of the mercurial column at 0° C. (32° Fahr.) at Paris, which amounts in that latitude to 1·033 kilogrammes on the square centimètre. In the English system, *an atmosphere* is the pressure due to 29·905 inches of the mercurial column at 32° Fahr. at London, amounting there to nearly 14¾ lb weight on the square inch. The latter atmosphere is thus 0·99968 of that of the metrical system.

As regards the distribution of atmospheric pressure over the globe, there was little beyond conjecture, drawn from theoretical considerations, and for the most part erroneous, till the publication in 1868 of Buchan's memoir "On the Mean Pressure of the Atmosphere and the Prevailing Winds over the Globe."[1] By the monthly isobaric charts and copious tables which accompanied the memoir, this important physical problem was first approximately solved. Since then the British Admiralty has published charts showing the mean pressure of the atmosphere over the ocean.[2] The more important general conclusions regarding the geographical distribution of atmospheric pressure are the following:—

There are two regions of high pressure, the one north and the other south of the equator, passing completely round the globe as broad belts of high pressure. They enclose between them the low pressure of tropical regions, through the centre of which runs a narrower belt of still lower pressure, towards which the north and south trades blow. The southern belt of high pressure lies nearly parallel to the equator, and is of nearly uniform breadth throughout; but the belt north of the equator has a very irregular outline, and great differences in its breadth and in its inclination to the equator,—these irregularities being due to the unequal distribution of land and water in the northern hemisphere. Taking a broad view of the subject, there are only three regions of low pressure,—one round each pole, bounded by or contained within the belts of high pressure just referred to, and the equatorial belt of low pressure. The most remarkable of these, in so far as yet known, is the region of low pressure surrounding the south pole, which appears to remain pretty constant

[1] *Trans. Roy. Soc. Edin.*, vol. xxv. p. 575.

[2] *Physical Charts of the Pacific, Atlantic, and Indian Oceans*, Lond. 1872.

during the whole year. The depression round the north pole is divided into two distinct centres, at each of which there is a diminution of pressure greatly lower than the average north polar depression. These two centres lie in the north of the Atlantic and Pacific Oceans respectively. The distribution of pressure in the different months of the year differs widely from the annual average, particularly in January and July, the two extreme months. In January the highest pressures are over the continents of the northern hemisphere,—and the larger the continental mass the greater the pressure,—and the lowest pressures are over the northern portions of the Atlantic and Pacific, South America and South Africa, and the Antarctic Ocean. In the centre of Asia the mean pressure of the atmosphere in this month is fully 30·400 inches, whereas in the North Atlantic, round Iceland, it is only 29·340 inches, or upwards of an inch lower than in Central Asia. The area of high barometer is continued westwards through Central and Southern Europe, the North Atlantic between 5° and 45° N. lat., North America, except the north and north-west, and the Pacific for some distance on either side of 15° N. lat. It is thus an exaggerated form of the high belt of annual mean pressure, spreading, however, over a much greater breadth in North America, and a still greater breadth in Asia.

In July, on the other hand, the mean pressure of Central Asia is only 29·468 inches, or nearly an inch lower than during January; or, putting this striking result in other words, about a thirtieth of the pressure of the atmosphere is removed from this region during the hottest months of the year as compared with the winter season. The lowest pressures of the northern hemisphere are now distributed over the continents, and the larger the continental mass the greater is the depression. At the same time, the highest are over the ocean between 50° N. and 50° S. lat., particularly over the North Atlantic and the North Pacific between 25° and 40° N. lat., and in the southern hemisphere over the belt of high mean annual pressure, which in this month reaches its maximum height. Pressure is high in South Africa and in Australia, just as in the winter of the northern hemisphere pressures are high over the continents.

Over the ocean, if we except the higher latitudes, atmospheric pressure is more regular throughout the year than over the land. In the ocean to westwards of each of the continents there occurs at all seasons an area of high pressure, from 0·10 inch to 0·30 inch higher than what prevails on the coast westward of which it lies. The distance of these spaces of high pressure is generally about 30° of longitude; and their longitudinal axes lie, roughly speaking, about the zones of the tropics. The maximum is reached during the winter months, and these areas of high pressure are most prominently marked west of those continents which have the greatest breadth in 30° lat.; and the steepest barometric gradients are on their eastern sides. It is scarcely possible to over-estimate the importance of these regions of high and low mean pressures, from their intimate bearing on atmospheric physics, but more particularly from their vital connection with prevailing winds and the general circulation of the atmosphere. This relation will be apprehended when it is considered that winds are simply the flowing away of the air from regions where there is a surplus (regions of high pressure) to where there is a deficiency of air (regions of low pressure). Everywhere over the globe this transference takes place in strict accordance with Buys-Ballot's "Law of the Winds," which may be thus expressed:—The wind neither blows round the space of lowest pressure in circles returning on themselves, nor does it blow directly toward that space; but it takes a direction intermediate, approaching, however, more nearly to the direction and course of circular curves than of radii to a centre. More exactly, the angle is not a right angle, but from 45° to 80°. Keeping this relation between wind and the distribution of pressure in mind, the isobaric lines give the proximate causes of the prevailing winds over the globe, and through these the prominent features of climates. As regards the ocean, the prevailing winds indicate the direction of the drift-currents and other surface-currents, and thereby the anomalous distribution of the temperature of the sea as seen in the Chili, Guinea, and other ocean currents, and the peculiarly marked climates of the coasts past which these currents flow, are explained; for observations have now proved that the prevailing winds and surface-currents of all oceans are all but absolutely coincident.

As regards the annual march of pressure through the months of the year, curves representing it for the different regions of the earth differ from each other in every conceivable way. It is only when the results are set down in their proper places on charts of the globe that the subject can be well understood. When thus dealt with, many of the results are characterised by great beauty and simplicity. Thus, of all influences which determine the barometric fluctuation through the months, the most important are the temperature, and through the temperature the humidity. Comparing, then, the average pressure in January with that in July, which two months give the greatest possible contrasts of temperature, the following is the broad result:—

The January exceeds the July pressure over the whole of Asia except Kamtchatka and the extreme north-east, the greatest excess being near the centre of the continent; over Europe to south and east of a line drawn from the White Sea south-westward to the Naze, thence southward to the mouth of the Weser, then to Tours, Bordeaux, and after passing through the north of Spain, out to sea at Coruña; over North America, except the north-east and north-west. On the other hand, the July exceeds the January pressure generally over the whole of the southern hemisphere, over the northern part of the North Atlantic and regions immediately adjoining (the excess amounting in Iceland to 0·397 inch), and over the northern part of the North Pacific and surrounding regions. Thus the pressure which is so largely removed from the Old and New Continents of the northern hemisphere in July is transferred, partly to the southern hemisphere, and partly to the northern portions of the Atlantic and Pacific Oceans.

Atmospheric pressure is more uniformly distributed over the globe in April and October than in any of the other months. In May and November, being the months immediately following, occur the great annual rise and fall of temperature; and since these rapid changes take place at very different rates, according to the relative distribution of land and water in each region, a comparison of the geographical distribution of May with that for the year brings out in strong relief the more prominent causes which influence climate, and some of the more striking results of these causes. This comparison shows a diminution of pressure in May over tropical and sub-tropical regions, including nearly the whole of Asia, the southern half of Europe, and the United States. An excess prevails over North America to the north of the Lakes, over Arctic America, Greenland, the British Isles, and to the north of a line passing through the English Channel in a north-easterly direction to the Arctic Sea. The excess in the southern hemisphere includes the southern half of South America and of Africa, the whole of Australia, and adjacent parts of the ocean. The influence of the land of the southern hemisphere, which in this month is colder than the surrounding seas, brings about an excess of pressure; on the other hand, the influence of land over those regions

which are more immediately under the sun brings about a lower pressure, interesting examples of which occur in India, the Malayan Archipelago, and the Mediterranean, Black, and Caspian Seas. In many cases the lines of pressure follow more or less closely the contours of the coasts. Thus the diminution is greater over Italy and Turkey than over the Adriatic and Black Seas. The greatest diminution occurs in Central Asia, where it exceeds 0·200 inch, and the greatest excess round Iceland, where it exceeds 0·200 inch. It is to the position of Great Britain, with reference to the deficiency of pressure on the one hand and the excess on the other, that the general prevalence of east winds at this season is due. These easterly winds prevail over the whole of Northern Europe, as far south as a line drawn from Madrid, and passing in a north-easterly direction through Geneva, Munich, &c. To the south of this line the diminution of pressure is less, and over this region the winds which are in excess are not easterly, but southerly. Crossing the Mediterranean, and advancing on Africa, we approach another region of lower pressure, towards which easterly and north-easterly winds again acquire the ascendency, as at Malta, Algeria, &c.

This, in many cases great, variation of the pressure in the different months of the year must be kept carefully in view in deducing heights of places from observations made by travellers of the pressure of atmosphere, by the barometer or the temperature of boiling water. In reducing the observations, it is necessary to assume a sea-level pressure if the place is at a considerable distance from any meteorological observatory. Previous to the publication of Buchan's *Mean Pressure of the Atmosphere*, it appears that a mean sea-level pressure of 29·92 or 30·00 inches was in such cases universally assumed. The mean pressure at Barnaul, Siberia, being 29·536 inches in July, 30·293 inches in January, and 29·954 inches for the year, it follows that, by the former method of calculating the heights, observations made in January to ascertain the height of Lake Balkash would make the lake 350 feet too high, and observations made in July would make it 330 feet too low,—the difference of the two observations, each set being supposed to be made under the most favourable circumstances, and with the greatest accuracy, being 680 feet. This illustration will serve to account for many of the discrepancies met with in books regarding the heights of mountains and plateaus.

Of the periodical variations of atmospheric pressure, the most marked is the daily variation, which in tropical and sub-tropical regions is one of the most regular of recurring phenomena. In higher latitudes the diurnal oscillation is masked by the frequent fluctuations to which the pressure is subjected. If, however, hourly observations be regularly made for some time, the hourly oscillation will become apparent. The results show two maxima occurring from 9 to 11 A.M. and 9 to 11 P.M., and two minima occurring from 3 to 6 A.M. and 3 to 6 P.M. The following are the extreme variations for January, April, July, and October from the daily mean pressure at Calcutta, deduced from the observations made during six years, viz., 1857–62:—

	A.M.				P.M.			
	Min.	Hour.	Max.	Hour.	Min.	Hour.	Max.	Hour.
	Inch.		Inch.		Inch.		Inch.	
January......	− ·023	3	+ ·079	10	− ·053	4	+ ·010	10
April.........	− ·020	3	+ ·070	9	− ·071	4	+ ·016	10
July	− ·019	3	+ ·040	10	− ·051	4	+ ·029	10
October......	− ·026	3	+ ·064	9	− ·047	4	+ ·018	10

Similarly the maxima and minima at Vienna, with the hour of their occurrence, are as follows:—

	A.M.				P.M.			
	Min.	Hour.	Max.	Hour.	Min.	Hour.	Max.	Hour.
	Inch.		Inch.		Inch.		Inch.	
January......	− ·008	6	+ ·018	10	− ·020	3	+ ·012	10
April......	− ·003	5	+ ·021	10	− ·027	5	+ ·014	11
July	+ ·003	3	+ ·022	9	− ·028	5	+ ·009	11
October......	− ·010	6	+ ·020	10	− ·015	4	+ ·008	10

These two illustrations may be regarded as typical, to a large extent, of the diurnal barometric oscillations in tropical and temperate regions. At Calcutta the amounts are large, and the dates of the occurrence of the maxima and minima very regular from 3 to 4 and 9 to 10 A.M. and P.M. respectively. On the other hand, the oscillations at Vienna are much smaller and more variable in amount, and the dates of occurrence of the critical phases take place through a wider interval, viz., from 3 to 6 and 9 to 11 A.M. and P.M. respectively.

Though the diurnal barometric oscillations are among the best-marked of meteorological phenomena, at least in tropical and sub-tropical regions, yet none of these phenomena, except perhaps the electrical, could be named respecting whose geographical distribution so little is really known, whether as regards the amount of variation, the hour of occurrence of the critical phases, or, particularly, the physical causes on which the observed differences depend. This arises chiefly from the want of a sufficient number of ascertained facts; and to remedy this deficiency, observations have, in the preparation of this present article, been collected and calculated from upwards of 250 places in different parts of the globe, and the data set down on charts. The chief results of this inquiry are the following, attention being entirely confined to the chief oscillation, viz., that occurring from the A.M. maximum to the P.M. minimum.

The A.M. *Maximum.*—In January this occurs from 9 to 10 in tropical and temperate regions as far as 50° N. lat.; in higher latitudes the time of occurrence varies from 8 A.M. to noon. In July it occurs from 9 to 10 everywhere only as far as about 40° N. lat.; the time at Tiflis (41° 42′ N. lat.) being between 7 and 8 A.M. In higher latitudes the time varies from 8 to 11 A.M., the last hour being general in north-western Europe.

The P.M. *Minimum.*—In January this occurs from 3 to 4 P.M. nearly everywhere over the globe, a few exceptions occurring in north-western Europe, the extremes being 2 P.M. at Utrecht and 6 P.M. at St Petersburg. It is quite different in July, when the time from 3 to 4 P.M. is regularly kept as far north as about 40° N. lat. In higher latitudes the hour is very generally 5, but at some places it is as early as 4 P.M., and at others as late as 6 P.M.

In the northern hemisphere, in summer, the afternoon minimum falls to a greater extent below the mean of the day than the forenoon maximum rises above it, at 82 per cent. of the stations; but in winter the percentage is only 61. In the southern hemisphere the same relation is observed in the summer and winter months, thus showing that in the summer of both hemispheres the influence of the sun tends to lower the minimum at 3 to 4 P.M. to a greater extent than to raise the 9 to 10 A.M. maximum.

Decrease between Morning Maximum and Afternoon Minimum.—Of the four daily oscillations, this is the most important. When the amounts at different places are entered on charts of the globe, it is seen that the amplitude of this fluctuation is, speaking generally, greatest in the tropics, diminishing as we advance into higher latitudes; greater over the land than over the sea, increasing greatly on proceeding inland; nearly always greater with a dry than with a moist atmosphere; and generally, but by no means always, it is greatest in the month of highest

temperature and greatest dryness combined. The regions of largest amplitude include the East India Islands, Eastern Peninsula, India, Arabia, tropical Africa, and tropical South and Central America, where it either closely approaches or exceeds 0·100 inch. At Silchar, in Assam, it is 0·133 inch. In the tropical parts of the ocean the oscillation is from 0·020 to 0·030 inch less than on land. The influence of the Mediterranean Sea in lessening the amount over all regions bordering it is very strongly marked. The line showing an oscillation of 0·050 inch crosses North America about lat. 44°, curves southward at some distance from the east coast to lat. 23°, then north-eastward along the coast of Africa, passes eastwards near the north coast of that continent, thence strikes northwards, cutting the eastern part of the Black Sea, and eastward across the Caspian to a point to northward of Peking, and then bends southward to the Loo Choo Islands. The line of 0·020 inch cuts the N.W. of Spain and N.W. of France, and runs northward through Great Britain as far as the Tweed, thence to Christiania, then southwards to Copenhagen and to Cracow, the latitude of which it follows eastward through Asia.

The more marked seasonal changes are these:—In India the oscillations during the dry and wet seasons, or in January and July, respectively, are—Bombay, 0·120 and 0·067 inch; Poonah, 0·133 and 0·059 inch; and Calcutta, 0·132 and 0·091 inch. At Madras, where the rain-bringing characters of the monsoons are reversed, the numbers are 0·114 and 0·115 inch, and at Roorkee, where rain falls all the year round, 0·088 and 0·079. Again, at Aden, in Arabia, where the weather of July is peculiarly hot and dry, the oscillation in December is 0·106, but in July it rises to 0·137 inch. The point to be insisted on here is, that, whatever be the cause or causes to which the daily barometric oscillation is due, the absolute amount is largely dependent on comparatively local influences.

While illustrations similar to the above may be adduced from many other parts of the globe, showing the influence in the same direction of prevailing dry or wet, hot or cold seasons on the amplitude of the oscillation, the North Atlantic and regions adjoining present an apparent exception to the law which seems to be indicated by these results. The whole of the North Atlantic, particularly north of lat. 20°, and the sea-boards which bound it, to which the Mediterranean and its immediate sea-board may be added, are strikingly characterised by a small summer oscillation; and this diminution is most strongly marked along the eastern part of the ocean. Thus, in July, at Ponta Delgada, in the Azores, the oscillation is only 0·06 inch; at Angra do Heroisma, also in the Azores, 0·010 inch; at Funchal, Madeira, 0·011 inch; at Oporto, 0·018; Lisbon, 0·030; and Lagos, 0·021; at Naples and Palermo, 0·008; and at Malta, 0·020 inch. Now, with reference to this extensive region, it is to be noted that the rainfall of July is either zero or very small; and yet with this dry state of the atmosphere and high temperature (the annual maximum occurring at the time), this oscillation is extraordinarily diminished, being exactly the reverse of what takes place during the dry and wet seasons in India. The diminution on the western half of the Atlantic, though not so great, is also striking, the January and July oscillations being 0·056 and 0·036 inch in Barbadoes, 0·080 and 0·056 at Jamaica, 0·082 and 0·054 at Havanna, 0·053 and 0·024 in the Bahamas, and 0·054 and 0·022 in Bermuda. Over the whole of the region here indicated the rainfall of July is largely in excess of that of January. The apparently exceptional character of this region is probably due to the circumstance, that at this time of the year the sun's rays fall perpendicularly over a more diversified surface of the earth, that is, on a greater extent of land, than at any other season. At this time the Mediterranean, which is completely shut in by land, and the Atlantic, which is bounded by two great continents, show a much smaller oscillation than prevails over the land adjoining them, and the lines of equal oscillation now attain their annual maximum. On the other hand, in January, when the sun's rays fall perpendicularly over the most uniform surface, or over the maximum extent of ocean, the lines are almost everywhere parallel with the parallels of latitude.

Again, on advancing inland from the Atlantic, the effects of comparatively local influences are very striking, as the following mean July oscillations, from places situated in lines running in different directions, show:—Dublin, 0·012; Oxford, 0·022; Ostend, 0·009; Brussels, 0·019; Vienna, 0·049; Odessa, 0·024; and Tiflis, 0·077: Limerick, 0·010; Helston, 0·007; Paris, 0·020; Geneva, 0·045; Turin, 0·052; Rome, 0·036; Palermo, 0·008; and Malta, 0·020. But the most remarkable illustration is the following, the places being all situated between 38° and 42° N. lat.: San Francisco, 0·068; Fort Churchhill, 0·091; Washington, 0·063; Angra do Heroisma, 0·006; Lisbon, 0·030; Campo Maior, 0·054; Palermo, 0·008; Tiflis, 0·077; and Peking, 0·060.

It follows from what has been stated that much which has been written regarding these fluctuations, and in explanation of them, does not rest on facts; and nearly everything yet requires to be done in the way of collecting data towards the representation and explanation of the daily oscillations of atmospheric pressure which are, as regards two-thirds of the globe, perhaps, as already stated, the most regular of recurring phenomena, and an explanation of which cannot but throw much light on many of the more important and difficult problems of the atmosphere. The data chiefly required are—barometric data from which the amplitude of the four daily oscillations can be represented in their distribution and times of occurrence for each of the months; temperature data, comparable *inter se*, from which the diurnal march of temperature for each month can be ascertained; hygrometric data for hourly values; rain data also for the hours; wind observations conducted on a satisfactory and uniform plan; together with magnetic and electrical observations. It is singularly unfortunate that the disposition of meteorologists of recent years has been to recommend as hours of observations for places which observe only twice or thrice daily, hours which do not correspond with the times when the great barometric and thermometric daily phases occur; hence these phases cannot be noted except at the great observatories, which are too few and far apart to give sufficient data for the proper discussion of many of those questions.

Since the two maxima of daily pressure occur when the temperature is about the mean of the day, and the two minima when it is at its highest and lowest respectively, there is thus suggested a connection between the daily barometric oscillations and the daily march of temperature; and similarly a connection with the daily march of the amount of vapour and humidity of the air. The view entertained by many of the causes of the daily oscillations may be thus stated:—The *forenoon maximum* is conceived to be due to the rapidly increasing temperature, and the rapid evaporation owing to the great dryness of the air at this time of the day, and to the increased elasticity of the lowermost stratum of air which results therefrom, until a steady ascending current has set in. As the day advances, the vapour becomes more equally diffused upwards through the air, an ascending current, more or less strong and steady, is set in motion, a diminution of elasticity follows, and the pressure falls to the *afternoon minimum*. From this point the temperature declines, a system of descending currents set in, and the air of the lowermost stratum

approaches more nearly the point of saturation, and from the increased elasticity, the pressure rises to the *evening maximum*. As the deposition of dew proceeds, and the fall of temperature and consequent downward movement of the air are arrested, the elasticity is again diminished, and pressure falls to the *morning minimum*. Since the view propounded some years ago, that if the elastic force of vapour be subtracted from the whole pressure, what remains will show only one daily maximum and minimum, has not been confirmed by observation, it follows that the above explanation is quite insufficient to account for the phenomena; indeed, the view can be regarded in no other light than simply as a tentative hypothesis.

Singularly enough, Lamont and Broun, a few years ago, were led, independently of each other, to form an opinion that the daily barometric oscillations were due to the magneto-electric influence of the sun. It admits of no doubt, looking at the facts of the case so far as they have been disclosed, that the daily barometric oscillations originate with the sun, and that more than the sun's influence as exerted on the diurnal march of the temperature and humidity of the atmosphere is concerned in bringing them about. But from the facts adduced, it is equally certain that, be the originating cause what it may, its effects are enormously modified by the distribution of land and water over the globe, by the wind, and by the absolute and relative humidity of the atmosphere. The smallness of the amount of the summer oscillation from the forenoon maximum to the afternoon minimum over the North Atlantic as far south as lat. 30°, and its diminished amount, as far south at least as the equator, will no doubt play an important part in the unravelling of this difficulty. One of the most important steps that could be taken would be an extensive series of observations from such countries as India, which offers such splendid contrasts of climate at all seasons, has a surface covered at one place with the richest vegetation, and at others with vast stretches of sandy deserts, and presents extensive plateaus and sharp ascending peaks—all which conditions are indispensable in collecting the data required for the solution of this vital problem of atmospheric physics.

The ancients thought that air was one of the four elements from which all things originated, and this doctrine continued to prevail till 1774, when Priestley discovered oxygen gas, and showed it to be a constituent part of air. Nitrogen, the other constituent of air, first called *azote*, was discovered soon after, and the marked differences between these two gases could not fail to strike the most careless observer. It is remarkable that Scheele independently discovered both oxygen and nitrogen, and was the first to enunciate the opinion that air consists essentially of a mixture of these two gases. From experiments made by him to ascertain their relative volumes he concluded that the proportions are 27 volumes of oxygen and 73 volumes of nitrogen. It was left to Cavendish to show from 500 analyses that the relative proportions were practically constant, and that the proportion is 20·833 per cent. of oxygen. The results obtained by Cavendish, though not attended to for many years after they were published, have been shown by recent and more refined analyses to be wonderfully exact. The most recent analyses of specimens of air collected under circumstances which ensure that it is of average purity, give as a mean result the following:—

	Volume.	
Oxygen	20·96	per cent.
Nitrogen	79·00	„
Carbonic acid	0·04	„
	100·00	

The circumstances under which these proportions vary, and the other gases and substances which are found in the air, will be afterwards adverted to.

Besides these three constituents of air, there is a fourth, viz., the vapour of water, from which no air, even at the lowest temperatures yet observed, is wholly free, so that absolutely dry air does not exist in the free atmosphere. The dry air of the atmosphere—oxygen (inclusive of ozone), nitrogen, and carbonic acid—is always a gas, and its quantity is constant from year to year; but the vapour of water does not always remain in the gaseous state, and the quantity present in the atmosphere is, by the processes of evaporation and condensation, varying every instant. Water evaporates at all temperatures, even the lowest, and rises into the air in the form of an invisible elastic gas called aqueous vapour. The elasticity of vapour varies with the temperature. At 0° Fahr. it is capable of sustaining a pressure equal to 0·044 inch of the mercurial barometer, as calculated from Regnault's experiments; at 32° (freezing), 0·181 inch; at 60°, 0·518 inch; at 80°, 1·023 inch; and at 100°, 1·918 inch, being nearly $\frac{1}{15}$ the average pressure of the atmosphere.

In investigating the hygrometry of the atmosphere, the chief points to be ascertained are—(1), the temperature of the air; (2), the dew-point; (3), the elastic force of vapour, or the amount of barometric pressure due to the vapour present; (4), the quantity of vapour in, say, a cubic foot of air; (5), the additional vapour required to saturate a cubic foot of air; (6), the relative humidity; and (7), the weight of a cubic foot of air at the pressure at the time of observation. The vapour of the atmosphere is observed by means of the hygrometer (see HYGROMETER), of which it is only necessary here to refer to *Regnault's* as the most exact, and *August's* as the most convenient, and, consequently, the one in most general use. August's hygrometer consists of a dry and a wet bulb, with which are observed the temperature of the air and the temperature of evaporation. Of these two observed data, the formula of reduction, as deduced from Apjohn's investigations, is as follows:—Let F be the elastic force of saturated vapour at the dew-point, f the elastic force at the temperature of evaporation, d the difference between the dry and wet bulb, and b the barometric pressure, then

$$F = f - \frac{d}{88} \times \frac{b}{30}$$

when the reading of the wet bulb is above 32°; and

$$F = f - \frac{d}{96} \times \frac{b}{30}$$

when below it. From Regnault's values of the elastic force of vapour, f is found, and d and b being observed, F is calculated. From F the dew-point is found. In calculating relative humidity, saturation is usually assumed to be 100, perfectly dry air 0. The humidity is found by dividing the elastic force at the dew-point by the elastic force at the temperature of the air, and multiplying the quotient by 100.

The elastic force may be regarded as representing approximately the absolute quantity of vapour suspended in the air. It may be termed the absolute humidity of the atmosphere. Since the chief disturbing influences at work in the atmosphere are the forces called into play by its aqueous vapour, a knowledge of the geographical distribution of this constituent through the months of the year is of the utmost possible importance. Hence every effort ought to be made to place the observation of the hygrometry of the air, and the reduction of the observed data, on a sounder basis than has yet been done. As regards geographical distribution, the elastic force is greatest within the tropics, and diminishes towards the poles; it is greater over

the ocean, and decreases on advancing inland; greater in summer than in winter; and greater at midday than in the morning. It diminishes with the height generally; but in particular cases, different strata are superimposed on each other, differing widely as regards dryness and humidity, and the transitions from the one to the other are often sharp and sudden.

The relative humidity of the air may be regarded as the degree of approach to saturation. It is greatest near the surface of the earth during night, when the temperature, being at or near the daily minimum, approaches the dew-point; it is also great in the morning, when the sun's rays have evaporated the dew, and the vapour is as yet only diffused a little way upwards; and it is least during the greatest heat of the day.

Between the humidity, both absolute and relative, of the air and the temperature there is a vital and all-important connection. Observation shows that when the quantity of vapour in the air is great, and also when the relative humidity is high, temperature falls little during the night, even though the sky be perfectly clear; but when the quantity of vapour is small, or the relative humidity is low, temperature rapidly falls. On the other hand, during the day the temperature rises slowly, when the quantity of vapour is great, or relative humidity high, even though the sky be clear; but when the quantity of vapour is small, and humidity low, temperature rapidly rises. These facts are explained by the circumstance that perfectly dry air is diathermanous, that is, it allows radiant heat to pass through it without being sensibly warmed thereby. Add vapour to this air, and its diathermancy is diminished. The diathermancy is also reduced if the temperature approach nearer to the dew-point; in other words, if the relative humidity be increased. Hence, with an increase of vapour or with increased humidity, the effects of both solar and terrestrial radiation are much less felt on the surface of the earth—the vapour screen performing, in truth, one of the most important conservative functions of the atmosphere.

Since ascending currents fall in temperature as they ascend, through diminished pressure and consequent dilatation, they increase their relative humidity; and since descending currents increase in temperature, and consequently reduce their relative humidity, it follows that, over a region from which ascending currents rise, solar and terrestrial radiation is very considerably obstructed, but over a region upon which currents descend, radiation is much less obstructed. Most of our exceptionally hot summer and cold winter weather is to be explained in this way, on which occasions there is generally observed a high barometric pressure overspreading a comparatively limited region, on which a slow downward movement of the air proceeds.

Of the solar heat which reaches the surface of the globe, that part which falls on the land may be regarded as wholly absorbed by the thin superficial layer exposed to the heating rays; and since there is no mobility in the particles of the land, the heat can be communicated downwards only by conduction. On the other hand, the solar heat which falls on water is not, as in the case of land, arrested at the surface, but penetrates to a considerable depth, the heating effect being in the case of clear water appreciably felt at a depth of from 500 to 600 feet. Since the heat daily received by the ocean from the sun is diffused downwards through a very considerable depth, the surface of the ocean on which the atmosphere rests is much less heated during the day than is the surface of the land. Similarly it is also less cooled during the night by terrestrial radiation.

This points to a chief acting force on which the great movements of the atmosphere depend, viz., simultaneous local irregularities in the distribution of temperature in the atmosphere. The local expansion of the atmosphere by heat during the day is greatest over land, where the air is clear, dry, and comparatively calm, and least over the ocean, where the sky is clouded, and the air loaded with moisture. On the other hand, the local contraction by cold during night is greatest over land, where the air is clear, dry, and calm, or nearly so, and least over the ocean, where the air is clouded, and loaded with moisture. As familiar illustrations of atmospheric movements resulting from local expansions by heat and contractions by cold, we may refer to the land and sea breezes, and what depend upon exactly the same principle, the dry and rainy monsoons in different parts of the globe. But the illustration of the principle on the broadest scale is the system of atmospheric circulation known as the equatorial and polar currents of the atmosphere, which originate in the unequal heating by the sun of the equatorial, temperate, and polar regions.

The other principal motive force in atmospheric circulation depends on the aqueous vapour. The many ways in which this element acts as a motive force will be seen when it is considered that a large quantity of sensible heat disappears in the process of evaporation, and reappears in the process of condensation of the vapour into rain or cloud; that saturated air is specifically lighter than dry air; and that the absolute and relative amount of the vapour powerfully influences both solar and terrestrial radiation. The question to be carefully considered here is, how in these ways the vapour produces local irregularities in the distribution of atmospheric pressure, thus giving rise to aerial movements which set in to restore the equilibrium that has thus been disturbed.

It is from these local irregularities—using the word local in a very wide sense—in the distribution of atmospheric pressure, whether the irregularities originate in the temperature or aqueous vapour, that all winds, from the lightest breeze to the most destructive hurricane, take their rise; for, as already stated, wind is merely the flowing away of the air from where there is a surplus of it to where there is a deficiency.

In examining weather charts embracing a considerable portion of the earth's surface, such, for instance, as those published in the *Journal of the Scottish Meteorological Society*, vol. ii. p. 198, which include a large part of the northern hemisphere, there are seen two different systems of pressure changing their forms and positions on the globe from day to day—one set being systems of low pressure marked off by concentric isobarics enclosing pressures successively lower as the central space is approached, and the other set being systems of high pressure marked off by roughly concentric isobarics bounding pressures successively higher towards their centres. These two systems are essentially distinct from each other, and without some knowledge of them the circulation of the atmosphere cannot be understood.

1. *Areas of Low Pressure, or Cyclones.*—The annexed woodcut, fig. 1, is a good representation of a cyclone which passed over north-western Europe on the morning of 2d November 1863. The pressure in the central space is 28·9 inches, from which it rises successively, as shown by the isobarics, to 29·1, 29·3, 29·5, 29·7, and 29·9 inches. The arrows show the direction and force of the wind, the force rising with the number of feathers on the arrows. The two chief points to be noted are the following:—(1.) The *direction* of the arrows shows a vorticose motion of the air inwards upon the space of lowest pressure, the motion being contrary to that of the hands of a watch. It will be observed that the winds blow in conformity with what is known as Buys-Ballot's "Law of the Winds," already

referred to, but which may be otherwise thus put:—Stand with your back to the wind, and the lowest barometer, or centre of depression, will be to your left in the northern hemisphere (in the southern hemisphere to the right); this rule holds universally. (2.) The *force* of the wind is proportional to the barometric gradient, or the quotient of the distance between two places stated in miles by the difference of pressure stated in inches of mercury as observed at the two places. Hence, in the Channel, where the isobarics are close together, winds are high, but in the north of Scotland, where the isobarics are far apart, winds are light. This rule also holds universally, though the exact relation requires still to be worked out by observation. As regards the important climatic elements of temperature and moisture, the air in the S.S.E. half of the cyclone is mild and humid, and much rain falls; but in the other half it is cold and dry, and little rain falls. A succession of low pressures passing eastward, in a course lying to northwards of Great Britain, is the characteristic of an open winter in Great Britain; on the other hand, if the cyclones follow a course lying to the southward, the winters are severe. This is a chief point of climatic importance connected with the propagation eastward of these cyclonic areas.

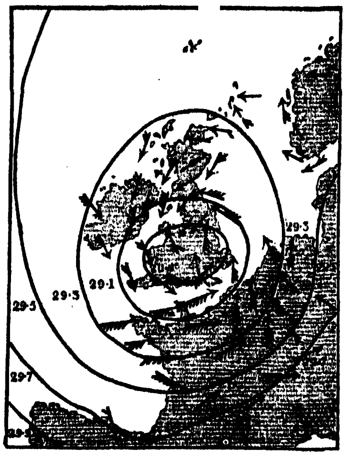

FIG. 1.—Weather chart, showing cyclone.

2. *Areas of High Pressures, or Anticyclones.*—The accompanying weather chart, fig. 2, for 2–4th August 1868, represents an anticyclone or region of high pressure, which overspread the greater part of Europe at that time. Here the highest pressure is in the centre of the system, and, as usually happens, the isobarics are less symmetrical than those near the centre of a cyclone. The winds, as usual in anticyclones, are light; this, however, is the essential point of difference—the winds do not flow inwards upon the centre, but outwards from the region of high pressure; and it will be observed that in many cases they cut the isobarics at nearly right angles. Another important point of difference is in the air over the region covered by the anticyclone being, particularly in its central portion, very dry, and either clear or nearly free from clouds.

FIG. 2.—Weather chart, showing anticyclone.

Climatically, the significance of the anticyclone consists in the space covered for the time by it being, on account of its dryness and clearness, more fully under the influence of both solar and terrestrial radiation; and consequently in winter it is accompanied with great cold, and in summer with great heat. As shown by Buchan, in reviewing the weather of north-western Europe for 1868,[1] the intense heat which prevailed in Great Britain during 2–4th August of that year was due to the high barometric pressure accompanying this anticyclone, the comparative calmness of the atmosphere, the clearness of the sky, the dryness of the air, and the strong insolation which took place under these circumstances.

Thus, then, the tendency of the winds on the surface of the earth is to blow round and in upon the space where pressures are low and out of the space where pressures are high. Now, since vast volumes of air are in this way poured into the space where pressure is low, without increasing that pressure, and, on the other hand, vast volumes flow out of the space where pressure is high, without diminishing that pressure, it necessarily follows that the air poured in is not allowed to accumulate over the space, but must escape into other regions; and also that the air which flows out from the anticyclonic region must have its place supplied by fresh accessions from above. In other words, the central space of the cyclone is occupied by a vast ascending current, which after rising to a considerable height flows away as upper currents into surrounding regions; and the central space of the anticyclone is filled by a slowly descending current, which is fed from upper currents, blowing towards it from neighbouring regions. When the area of observation is made sufficiently wide, cyclones are seen to have one, or sometimes more, anticyclones in proximity to them, the better marked anticyclones having two, and sometimes more, cyclones in their vicinity. In fig. 2, a part of a cyclone in Iceland is seen, and another cyclone in the Crimea accompanied the anticyclone there figured. Hence the cyclone and the anticyclone are properly to be regarded as counterparts, belonging to one and the same great atmospheric disturbance.

From this it follows that observations of the winds cannot be conducted, and the results discussed, on the supposition that the general movement of the winds felt on the earth's surface is horizontal, it being evident that the circulation of the atmosphere is effected largely through systems of ascending and descending currents. The only satisfactory way of discussing the winds, viewed especially in their climatic relations, is that recently proposed by Köppen of St Petersburg, and applied by him with very fruitful results in investigating the weather of that place during 1872 and 1873. In attempting an explanation of these phenomena, we are met with several as yet insuperable obstacles:—(1.) An imperfect knowledge of the mode

[1] *Atlas Météorologique de l'Observatoire Impérial*, Année 1868, p. 39.

of formation and propagation of low-pressure systems; (2.) Imperfect knowledge of the relations of the formation of cloud and aqueous precipitation to barometric fluctuations; (3.) A want of information with reference to the merely mechanical effects of ascending, descending, and horizontal currents of air on the barometric pressure; in other words, we do not know how far the barometric pressure is an indication of the mass of air in the column vertically over it, when that column is traversed by air-currents; (4.) An almost total absence of really good wind observations; and (5.) Deficient information in nearly everything that respects aqueous vapour—its relation to radiant heat, both solar and terrestrial; its mode of diffusion vertically and horizontally in the free atmosphere, especially from an evaporating surface; the influence which its condensation into cloud and rain exerts on aerial currents,—in regard to all which more satisfactory methods of observing this vital element, and discussing the results of observation, are greatly to be desired. There are here large important fields of inquiry awaiting experimental and observational physicists.

The law of the dilatation of gases, known as the "Law of Boyle" or "Law of Mariotte," is this: The volume occupied by a gas is in inverse ratio to the pressure under which it exists, if the temperature remains the same; or the density of a gas is proportioned to its pressure. Consequently, air under a pressure equal to that of two atmospheres will occupy only half the volume it occupied under the pressure of one atmosphere; under the pressure of three atmospheres, one-third of that volume, &c. By doubling the pressure we double the elasticity. If, however, the temperature be increased, and the air occupy the same space, the pressure will be increased; but if the pressure is to remain the same, the air must occupy a larger space. From Regnault's experiments, it is concluded that the co-efficient which denotes increase of elasticity for 1° Fahr. of air whose volume is constant equals ·002036; and that the co-efficient which denotes increase of volume for 1° Fahr. of air whose elasticity is constant equals ·002039.

Those portions of the atmosphere in contact with the earth are pressed upon by all the air above them. The air at the top of a mountain is pressed upon by all the air above it, while all the portion below it, or lying between the top of the mountain and the surface of the sea, exerts no pressure whatever upon it. Thus the pressure of the atmosphere constantly diminishes with the height. If, then, the pressure of the atmosphere at two heights be observed, and if at the same time the mean temperature and humidity of the whole stratum of air lying between the two levels were known, the difference in height between the two places could be calculated. For the development of this principle, see BAROMETRIC MEASUREMENTS OF HEIGHTS.

The air thus diminishing in density as we ascend, if it consists of ultimate atoms, as is no doubt the case, it follows that the limit of the atmosphere will be reached at the height where the force of gravity downwards upon a single particle is equal to the resisting force arising from the repulsive force of the particles. It was long supposed, from the results of observations on the refraction of light, that the height of the atmosphere did not exceed 45 miles; but from the observations of luminous meteors, whose true character as cosmical bodies was established a few years ago, it is inferred that the height of the atmosphere is at least 120 miles, and that, in an extremely attenuated form, it may even reach 200 miles.

Though there are considerable differences in the specific gravities of the four constituent gases of the atmosphere, viz., oxygen, nitrogen, carbonic acid gas, and aqueous vapour, there is yet no tendency to separation among them, owing to the law of diffusion obtaining among elastic fluids mixed together. While the proportion of these gases is in a general sense constant, there are, however, consistent differences in the amounts of oxygen and nitrogen in the air of unwholesome places, as first shown by Regnault. The following figures, showing the volume per cent. of oxygen, rest on the authority of Dr Angus Smith, who has given much attention to this subject:—Sea-shore of Scotland and Atlantic (lat. 43° 5′ N., long. 17° 12′ W.), 20·99; tops of Scottish hills, 20·98; in sitting-room feeling close but not excessively so, 20·89; backs of houses and closets, 20·70; under shafts in metalliferous mines, 20·424; when candles go out, 18·50; when it is very difficult to remain in the air many minutes, 17·20. The variations in the amounts of carbonic acid in different situations are great; thus—in the London parks it is ·0301; on the Thames, ·0343; where fields begin, ·0369; in London streets in summer, ·0380; during fogs in Manchester, ·0679; in workshops it rises to ·3000, and in the worst parts of theatres to ·3200; and the largest amount, found in Cornwall mines, is 2·5000.

Great differences have been observed by Dr A. Smith between country rain and town rain: country rain is neutral; town rain, on the other hand, is acid, and corrodes metals and even stones and bricks, destroying mortar rapidly, and readily spoiling many colours. Much information has been obtained regarding impurities in the air of towns and other places by examining the rain collected in different places. The air freest from impurities is that collected at the sea-coast and at considerable heights. Again, ammonia is found to diminish, while nitric acid increases, in ascending to, at least, habitable heights. As regards organic matter in the air, it corresponds to a considerable extent with the density of the population. As might have been supposed from the higher temperature, more nitric acid is contained in rain collected on the Continent than in the British Islands. This inquiry, which is only yet in its infancy, will doubtless continue to be vigorously prosecuted, particularly since we may hope thereby to arrive at the means of authoritatively defining the safe limits of the density of population, and the extent to which manufactures may be carried on within a given area. The influence of atmospheric impurities on the public health has received a good deal of attention.

The relation of weather to mortality is a very important inquiry, and though a good deal has been known regarding the question for some time, yet it has only recently been systematically inquired into by Dr Arthur Mitchell and Mr Buchan, the results of the investigation which deals with the mortality of London being published in the *Journal of the Scottish Meteorological Society* (New Series, Nos. 43 to 46). Considering the weather of the year as made up of several distinct climates differing from each other according to temperature and moisture and their relations to each other, it may be divided into six distinct climates, characterised respectively by cold, cold with dryness, dryness with heat, heat, heat with moisture, and cold with moisture. Each of these six periods has a peculiar influence in increasing or diminishing the mortality, and each has its own group of diseases which rise to the maximum, or fall to the minimum mortality, or are subject to a rapid increase or a rapid decrease. The mortality from all causes and at all ages shows a large excess above the average from the middle of November to the middle of April, from which it falls to the minimum in the end of May; it then slowly rises, and on the third week of July suddenly shoots up almost as high as the winter maximum of the year, at which it remains till the second week of August, falling thence as rapidly as it rose to a secondary minimum in October. Regarding the summer excess, which is so abrupt in its rise and fall, it is almost altogether

due to the enormous increase of the mortality among mere infants under one year of age; and this increase is due not only to deaths at one age, but to deaths from one class of diseases, viz., bowel complaints. If the deaths from bowel complaints be deducted from the deaths from all causes, there remains an excess of deaths in the cold months, and a deficiency in the warm months. In other words, the curve of mortality is regulated by the large number of deaths from diseases of the respiratory organs. The curve of mortality for London, if mere infants be excepted, has thus an inverse relation to the temperature, rising as the temperature falls, and falling as the temperature rises. On the other hand, in Victoria, Australia, where the summers are hotter and the winters milder, the curves of mortality and temperature are directly related to each other—mortality and temperature rising and falling together; the reason being that in Victoria deaths from bowel complaints are much greater, and those from diseases of the respiratory organs much less than in London.

The curves show that the maximum annual mortality from the different diseases groups around certain specific conditions of temperature and moisture combined. Thus, *cold and moist weather* is accompanied with a high death-rate from rheumatism, heart-diseases, diphtheria, and measles; *cold weather*, with a high death-rate from bronchitis, pneumonia, &c.; *cold and dry weather*, with a high death-rate from brain diseases, whooping-cough, convulsions; *warm and dry weather*, with a high death-rate from suicide and small-pox; *hot weather*, with a high death-rate from bowel complaints; and *warm moist weather* with a high death-rate from scarlet and typhoid fevers. (See CLIMATE.) (A. B.)

ATMOSPHERIC RAILWAY, a railway in which the pressure of air is used directly or indirectly to propel carriages, as a substitute for steam. It was devised at a time when the principles of propulsion were not so well understood as they are now, and when the dangers and inconveniences attendant on the use of locomotives were very much exaggerated. It had been long known that small objects could be propelled for great distances through tubes by air pressure, but a Mr Vallance, of Brighton, seems to have been the first to propose the application of this system to passenger traffic. He projected (about 1825) an atmospheric railway, consisting of a wooden tube about 6 feet 6 inches in diameter, with a carriage running inside it. A diaphragm fitting the tube, approximately air-tight, was attached to the carriage, and the air exhausted from the front of it by a stationary engine, so that the atmospheric pressure behind drove the carriage forward. Later inventors, commencing with Henry Pinkus (1835), for the most part kept the carriages altogether outside the tube, and connected them by a bar with a piston working inside it, this piston being moved by atmospheric pressure in the way just mentioned. The tube was generally provided with a slot upon its upper side, closed by a continuous valve or its equivalent, and arrangements were made by which this valve should be opened to allow the passage of the driving bar without permitting great leakage of air. About 1840, Messrs Clegg & Samuda made various experiments with an atmospheric tube constructed on this principle upon a portion of the West London Railway, near Wormwood Scrubs. The apparent success of these induced the Dublin and Kingstown Railway to adopt Clegg & Samuda's scheme upon an extension of their line from Kingstown to Dalkey, where it was in operation in 1844. Later on, the same system was adopted on a part of the South Devon line and in several other places, and during the years 1844–1846 the English and French patent records show a very large number of more or less practicable and ingenious schemes for the tubes, valves, and driving gear of atmospheric railways. The atmospheric system was nowhere permanently successful, but in all cases was eventually superseded by locomotives, the last atmospheric line being probably that at St Germains, which was worked until 1862. Apart from difficulties in connection with the working of the valve, the maintenance of the vacuum, &c., other great practical difficulties, which had not been indicated by the experiments, soon made themselves known in the working of the lines. Above all, it was found that stationary engines, whether hauling a rope or exhausting a tube, could never work a railway with anything like the economy or the convenience of locomotives, a point which is now regarded as settled by engineers, but which was not so thoroughly understood thirty years ago. Lately, the principle of the atmospheric railway has been applied on a very large scale in London and elsewhere, under the name of "PNEUMATIC DESPATCH" (*q.v.*), to the transmission of small parcels in connection with postal and telegraph work, for which purpose it has proved admirably adapted. (See paper by Prof. Sternberg of Carlsruhe in Hensinger von Waldegg's *Handbuch für specielle Eisenbahntechnik*, vol. i. pt. 2, cap. xvii.)

ATOM

ATOM (ἄτομος) is a body which cannot be cut in two. The atomic theory is a theory of the constitution of bodies, which asserts that they are made up of atoms. The opposite theory is that of the homogeneity and continuity of bodies, and asserts, at least in the case of bodies having no apparent organisation, such, for instance, as water, that as we can divide a drop of water into two parts which are each of them drops of water, so we have reason to believe that these smaller drops can be divided again, and the theory goes on to assert that there is nothing in the nature of things to hinder this process of division from being repeated over and over again, times without end. This is the doctrine of the infinite divisibility of bodies, and it is in direct contradiction with the theory of atoms.

The atomists assert that after a certain number of such divisions the parts would be no longer divisible, because each of them would be an atom. The advocates of the continuity of matter assert that the smallest conceivable body has parts, and that whatever has parts may be divided.

In ancient times Democritus was the founder of the atomic theory, while Anaxagoras propounded that of continuity, under the name of the doctrine of homœomeria (Ὁμοιομέρια), or of the similarity of the parts of a body to the whole. The arguments of the atomists, and their replies to the objections of Anaxagoras, are to be found in Lucretius.

In modern times the study of nature has brought to light many properties of bodies which appear to depend on the magnitude and motions of their ultimate constituents, and the question of the existence of atoms has once more become conspicuous among scientific inquiries.

We shall begin by stating the opposing doctrines of atoms and of continuity before giving an outline of the state of

molecular science as it now exists. In the earliest times the most ancient philosophers whose speculations are known to us seem to have discussed the ideas of number and of continuous magnitude, of space and time, of matter and motion, with a native power of thought which has probably never been surpassed. Their actual knowledge, however, and their scientific experience were necessarily limited, because in their days the records of human thought were only beginning to accumulate. It is probable that the first exact notions of quantity were founded on the consideration of number. It is by the help of numbers that concrete quantities are practically measured and calculated. Now, number is discontinuous. We pass from one number to the next *per saltum*. The magnitudes, on the other hand, which we meet with in geometry, are essentially continuous. The attempt to apply numerical methods to the comparison of geometrical quantities led to the doctrine of incommensurables, and to that of the infinite divisibility of space. Meanwhile, the same considerations had not been applied to time, so that in the days of Zeno of Elea time was still regarded as made up of a finite number of "moments," while space was confessed to be divisible without limit. This was the state of opinion when the celebrated arguments against the possibility of motion, of which that of Achilles and the tortoise is a specimen, were propounded by Zeno, and such, apparently, continued to be the state of opinion till Aristotle pointed out that time is divisible without limit, in precisely the same sense that space is. And the slowness of the development of scientific ideas may be estimated from the fact that Bayle does not see any force in this statement of Aristotle, but continues to admire the paradox of Zeno. (Bayle's *Dictionary*, art. "Zeno.") Thus the direction of true scientific progress was for many ages towards the recognition of the infinite divisibility of space and time.

It was easy to attempt to apply similar arguments to matter. If matter is extended and fills space, the same mental operation by which we recognise the divisibility of space may be applied, in imagination at least, to the matter which occupies space. From this point of view the atomic doctrine might be regarded as a relic of the old numerical way of conceiving magnitude, and the opposite doctrine of the infinite divisibility of matter might appear for a time the most scientific. The atomists, on the other hand, asserted very strongly the distinction between matter and space. The atoms, they said, do not fill up the universe; there are void spaces between them. If it were not so, Lucretius tells us, there could be no motion, for the atom which gives way first must have some empty place to move into.

> "Quapropter locus est intactus, inane, vacansque
> Quod si non esset, nulla ratione moveri
> Res possent; namque, officium quod corporis exstat,
> Officere atque obstare, id in omni tempore adesset
> Omnibus: haud igitur quicquam procedere posset,
> Principium quoniam cedendi nulla daret res."
> —*De Rerum Natura*, i. 335.

The opposite school maintained then, as they have always done, that there is no vacuum—that every part of space is full of matter, that there is a universal plenum, and that all motion is like that of a fish in the water, which yields in front of the fish because the fish leaves room for it behind.

> "Cedere squamigeris latices nitentibus aiunt
> Et liquidas aperire vias, quia post loca pisces
> Linquant, quo possint cedentes confluere undæ."
> —i. 373.

In modern times Descartes held that, as it is of the essence of matter to be extended in length, breadth, and thickness, so it is of the essence of extension to be occupied by matter, for extension cannot be an extension of nothing.

> "Ac proinde si quæratur quid fiet, si Deus auferat omne corpus quod in aliquo vase continetur, et nullum aliud in ablati locum venire permittat? respondendum est, vasis latera sibi invicem hoc ipso fore contigua. Cum enim inter duo corpora nihil interjacet, necesse est ut se mutuo tangant, ac manifeste repugnat ut distent, sive ut inter ipsa sit distantia, et tamen ut ista distantia sit nihil; quia omnis distantia est modus extensionis, et ideo sine substantia extensa esse non potest."—*Principia*, ii. 18.

This identification of extension with substance runs through the whole of Descartes's works, and it forms one of the ultimate foundations of the system of Spinoza. Descartes, consistently with this doctrine, denied the existence of atoms as parts of matter, which by their own nature are indivisible. He seems to admit, however, that the Deity might make certain particles of matter indivisible in this sense, that no creature should be able to divide them. These particles, however, would be still divisible by their own nature, because the Deity cannot diminish his own power, and therefore must retain his power of dividing them. Leibnitz, on the other hand, regarded his monad as the ultimate element of everything.

There are thus two modes of thinking about the constitution of bodies, which have had their adherents both in ancient and in modern times. They correspond to the two methods of regarding quantity—the arithmetical and the geometrical. To the atomist the true method of estimating the quantity of matter in a body is to count the atoms in it. The void spaces between the atoms count for nothing. To those who identify matter with extension, the volume of space occupied by a body is the only measure of the quantity of matter in it.

Of the different forms of the atomic theory, that of Boscovich may be taken as an example of the purest monadism. According to Boscovich matter is made up of atoms. Each atom is an indivisible point, having position in space, capable of motion in a continuous path, and possessing a certain mass, whereby a certain amount of force is required to produce a given change of motion. Besides this the atom is endowed with potential force, that is to say, that any two atoms attract or repel each other with a force depending on their distance apart. The law of this force, for all distances greater than say the thousandth of an inch, is an attraction varying as the inverse square of the distance. For smaller distances the force is an attraction for one distance and a repulsion for another, according to some law not yet discovered. Boscovich himself, in order to obviate the possibility of two atoms ever being in the same place, asserts that the ultimate force is a repulsion which increases without limit as the distance diminishes without limit, so that two atoms can never coincide. But this seems an unwarrantable concession to the vulgar opinion that two bodies cannot co-exist in the same place. This opinion is deduced from our experience of the behaviour of bodies of sensible size, but we have no experimental evidence that two atoms may not sometimes coincide. For instance, if oxygen and hydrogen combine to form water, we have no experimental evidence that the molecule of oxygen is not in the very same place with the two molecules of hydrogen. Many persons cannot get rid of the opinion that all matter is extended in length, breadth, and depth. This is a prejudice of the same kind with the last, arising from our experience of bodies consisting of immense multitudes of atoms. The system of atoms, according to Boscovich, occupies a certain region of space in virtue of the forces acting between the component atoms of the system and any other atoms when brought near them. No other system of atoms can occupy the same region of space at the same time, because, before it could do so, the mutual

action of the atoms would have caused a repulsion between the two systems insuperable by any force which we can command. Thus, a number of soldiers with firearms may occupy an extensive region to the exclusion of the enemy's armies, though the space filled by their bodies is but small. In this way Boscovich explained the apparent extension of bodies consisting of atoms, each of which is devoid of extension. According to Boscovich's theory, all action between bodies is action at a distance. There is no such thing in nature as actual contact between two bodies. When two bodies are said in ordinary language to be in contact, all that is meant is that they are so near together that the repulsion between the nearest pairs of atoms belonging to the two bodies is very great.

Thus, in Boscovich's theory, the atom has continuity of existence in time and space. At any instant of time it is at some point of space, and it is never in more than one place at a time. It passes from one place to another along a continuous path. It has a definite mass which cannot be increased or diminished. Atoms are endowed with the power of acting on one another by attraction or repulsion, the amount of the force depending on the distance between them. On the other hand, the atom itself has no parts or dimensions. In its geometrical aspect it is a mere geometrical point. It has no extension in space. It has not the so-called property of Impenetrability, for two atoms may exist in the same place. This we may regard as one extreme of the various opinions about the constitution of bodies.

The opposite extreme, that of Anaxagoras—the theory that bodies apparently homogeneous and continuous are so in reality—is, in its extreme form, a theory incapable of development. To explain the properties of any substance by this theory is impossible. We can only admit the observed properties of such substance as ultimate facts. There is a certain stage, however, of scientific progress in which a method corresponding to this theory is of service. In hydrostatics, for instance, we define a fluid by means of one of its known properties, and from this definition we make the system of deductions which constitutes the science of hydrostatics. In this way the science of hydrostatics may be built upon an experimental basis, without any consideration of the constitution of a fluid as to whether it is molecular or continuous. In like manner, after the French mathematicians had attempted, with more or less ingenuity, to construct a theory of elastic solids from the hypothesis that they consist of atoms in equilibrium under the action of their mutual forces, Stokes and others showed that all the results of this hypothesis, so far at least as they agreed with facts, might be deduced from the postulate that elastic bodies exist, and from the hypothesis that the smallest portions into which we can divide them are sensibly homogeneous. In this way the principle of continuity, which is the basis of the method of Fluxions and the whole of modern mathematics, may be applied to the analysis of problems connected with material bodies by assuming them, for the purpose of this analysis, to be homogeneous. All that is required to make the results applicable to the real case is that the smallest portions of the substance of which we take any notice shall be sensibly of the same kind. Thus, if a railway contractor has to make a tunnel through a hill of gravel, and if one cubic yard of the gravel is so like another cubic yard that for the purposes of the contract they may be taken as equivalent, then, in estimating the work required to remove the gravel from the tunnel, he may, without fear of error, make his calculations as if the gravel were a continuous substance. But if a worm has to make his way through the gravel, it makes the greatest possible difference to him whether he tries to push right against a piece of gravel, or directs his course through one of the intervals between the pieces; to him, therefore, the gravel is by no means a homogeneous and continuous substance.

In the same way, a theory that some particular substance, say water, is homogeneous and continuous may be a good working theory up to a certain point, but may fail when we come to deal with quantities so minute or so attenuated that their heterogeneity of structure comes into prominence. Whether this heterogeneity of structure is or is not consistent with homogeneity and continuity of substance is another question.

The extreme form of the doctrine of continuity is that stated by Descartes, who maintains that the whole universe is equally full of matter, and that this matter is all of one kind, having no essential property besides that of extension. All the properties which we perceive in matter he reduces to its parts being movable among one another, and so capable of all the varieties which we can perceive to follow from the motion of its parts (*Principia*, ii. 23). Descartes's own attempts to deduce the different qualities and actions of bodies in this way are not of much value. More than a century was required to invent methods of investigating the conditions of the motion of systems of bodies such as Descartes imagined. But the hydrodynamical discovery of Helmholtz that a vortex in a perfect liquid possesses certain permanent characteristics, has been applied by Sir W. Thomson to form a theory of vortex atoms in a homogeneous, incompressible, and frictionless liquid, to which we shall return at the proper time.

Outline of Modern Molecular Science, and in particular of the Molecular Theory of Gases.

We begin by assuming that bodies are made up of parts, each of which is capable of motion, and that these parts act on each other in a manner consistent with the principle of the conservation of energy. In making these assumptions, we are justified by the facts that bodies may be divided into smaller parts, and that all bodies with which we are acquainted are conservative systems, which would not be the case unless their parts were also conservative systems.

We may also assume that these small parts are in motion. This is the most general assumption we can make, for it includes, as a particular case, the theory that the small parts are at rest. The phenomena of the diffusion of gases and liquids through each other show that there may be a motion of the small parts of a body which is not perceptible to us.

We make no assumption with respect to the nature of the small parts—whether they are all of one magnitude. We do not even assume them to have extension and figure. Each of them must be measured by its mass, and any two of them must, like visible bodies, have the power of acting on one another when they come near enough to do so. The properties of the body, or medium, are determined by the configuration and motion of its small parts.

The first step in the investigation is to determine the amount of motion which exists among the small parts, independent of the visible motion of the medium as a whole. For this purpose it is convenient to make use of a general theorem in dynamics due to Clausius.

When the motion of a material system is such that the time-average of the quantity $\Sigma(mx^2)$ remains constant, the state of the system is said to be that of stationary motion. When the motion of a material system is such that the sum of the moments of inertia of the system, about three axes at right angles through its centre of mass, never varies by more than small quantities from a constant value, the system is said to be in a state of stationary motion.

The kinetic energy of a particle is half the product of its mass into the square of its velocity, and the kinetic energy of a system is the sum of the kinetic energy of all its parts.

When an attraction or repulsion exists between two points, half the product of this stress into the distance between the two points is called the *virial* of the stress, and is reckoned positive when the stress is an attraction, and negative when it is a repulsion. The virial of a system is the sum of the virials of the stresses which exist in it. If the system is subjected to the external stress of the pressure of the sides of a vessel in which it is contained, this stress will introduce an amount of virial $\frac{3}{2}p\mathrm{V}$, where p is the pressure on unit of area and V is the volume of the vessel.

The theorem of Clausius may now be stated as follows:— In a material system in a state of stationary motion the time-average of the kinetic energy is equal to the time-average of the virial. In the case of a fluid enclosed in a vessel

$$\tfrac{1}{2}\Sigma(m\overline{v^2}) = \tfrac{3}{2}p\mathrm{V} + \tfrac{1}{2}\Sigma\Sigma(\mathrm{R}r),$$

where the first term denotes the kinetic energy, and is half the sum of the product of each mass into the mean square of its velocity. In the second term, p is the pressure on unit of surface of the vessel, whose volume is V, and the third term expresses the virial due to the internal actions between the parts of the system. A double symbol of summation is used, because every pair of parts between which any action exists must be taken into account. We have next to show that in gases the principal part of the pressure arises from the motion of the small parts of the medium, and not from a repulsion between them.

In the first place, if the pressure of a gas arises from the repulsion of its parts, the law of repulsion must be inversely as the distance. For, consider a cube filled with the gas at pressure p, and let the cube expand till each side is n times its former length. The pressure on unit of surface according to Boyle's law is now $\frac{p}{n^3}$, and since the area of a face of the cube is n^2 times what it was, the whole pressure on the face of the cube is $\frac{1}{n}$ of its original value. But since everything has been expanded symmetrically, the distance between corresponding parts of the air is now n times what it was, and the force is n times less than it was. Hence the force must vary inversely as the distance.

But Newton has shown (*Principia*, bk. i. prop. 93) that this law is inadmissible, as it makes the effect of the distant parts of the medium on a particle greater than that of the neighbouring parts. Indeed, we should arrive at the conclusion that the pressure depends not only on the density of the air but on the form and dimensions of the vessel which contains it, which we know not to be the case.

If, on the other hand, we suppose the pressure to arise entirely from the motion of the molecules of the gas, the interpretation of Boyle's law becomes very simple. For, in this case

$$p\mathrm{V} = \tfrac{1}{3}\Sigma(m\overline{v^2}).$$

The first term is the product of the pressure and the volume, which according to Boyle's law is constant for the same quantity of gas at the same temperature. The second term is two-thirds of the kinetic energy of the system, and we have every reason to believe that in gases when the temperature is constant the kinetic energy of unit of mass is also constant. If we admit that the kinetic energy of unit of mass is in a given gas proportional to the absolute temperature, this equation is the expression of the law of Charles as well as of that of Boyle, and may be written—

$$p\mathrm{V} = \mathrm{R}\theta,$$

where θ is the temperature reckoned from absolute zero, and R is a constant. The fact that this equation expresses with considerable accuracy the relation between the volume, pressure, and temperature of a gas when in an extremely rarified state, and that as the gas is more and more compressed the deviation from this equation becomes more apparent, shows that the pressure of a gas is due almost entirely to the motion of its molecules when the gas is rare, and that it is only when the density of the gas is considerably increased that the effect of direct action between the molecules becomes apparent.

The effect of the direct action of the molecules on each other depends on the number of pairs of molecules which at a given instant are near enough to act on one another. The number of such pairs is proportional to the square of the number of molecules in unit of volume, that is, to the square of the density of the gas. Hence, as long as the medium is so rare that the encounter between two molecules is not affected by the presence of others, the deviation from Boyle's law will be proportional to the square of the density. If the action between the molecules is on the whole repulsive, the pressure will be greater than that given by Boyle's law. If it is, on the whole, attractive, the pressure will be less than that given by Boyle's law. It appears, by the experiments of Regnault and others, that the pressure does deviate from Boyle's law when the density of the gas is increased. In the case of carbonic acid and other gases which are easily liquefied, this deviation is very great. In all cases, however, except that of hydrogen, the pressure is less than that given by Boyle's law, showing that the virial is on the whole due to *attractive* forces between the molecules.

Another kind of evidence as to the nature of the action between the molecules is furnished by an experiment made by Dr Joule. Of two vessels, one was exhausted and the other filled with a gas at a pressure of 20 atmospheres; and both were placed side by side in a vessel of water, which was constantly stirred. The temperature of the whole was observed. Then a communication was opened between the vessels, the compressed gas expanded to twice its volume, and the work of expansion, which at first produced a strong current in the gas, was soon converted into heat by the internal friction of the gas. When all was again at rest, and the temperature uniform, the temperature was again observed. In Dr Joule's original experiments the observed temperature was the same as before. In a series of experiments, conducted by Dr Joule and Sir W. Thomson on a different plan, by which the thermal effect of free expansion can be more accurately measured, a slight cooling effect was observed in all the gases examined except hydrogen. Since the temperature depends on the velocity of agitation of the molecules, it appears that when a gas expands without doing external work the velocity of agitation is not much affected, but that in most cases it is slightly diminished. Now, if the molecules during their mutual separation act on each other, their velocity will increase or diminish according as the force is repulsive or attractive. It appears, therefore, from the experiments on the free expansion of gases, that the force between the molecules is small but, on the whole, attractive.

Having thus justified the hypothesis that a gas consists of molecules in motion, which act on each other only when they come very close together during an encounter, but which, during the intervals between their encounters which constitute the greater part of their existence, are describing free paths, and are not acted on by any molecular force, we proceed to investigate the motion of such a system.

The mathematical investigation of the properties of such

a system of molecules in motion is the foundation of molecular science. Clausius was the first to express the relation between the density of the gas, the length of the free paths of its molecules, and the distance at which they encounter each other. He assumed, however, at least in his earlier investigations, that the velocities of all the molecules are equal. The mode in which the velocities are distributed was first investigated by the present writer, who showed that in the moving system the velocities of the molecules range from zero to infinity, but that the number of molecules whose velocities lie within given limits can be expressed by a formula identical with that which expresses in the theory of errors the number of errors of observation lying within corresponding limits. The proof of this theorem has been carefully investigated by Boltzmann,[1] who has strengthened it where it appeared weak, and to whom the method of taking into account the action of external forces is entirely due.

The mean kinetic energy of a molecule, however, has a definite value, which is easily expressed in terms of the quantities which enter into the expression for the distribution of velocities. The most important result of this investigation is that when several kinds of molecules are in motion and acting on one another, the mean kinetic energy of a molecule is the same whatever be its mass, the molecules of greater mass having smaller mean velocities. Now, when gases are mixed their temperatures become equal. Hence we conclude that the physical condition which determines that the temperature of two gases shall be the same is that the mean kinetic energies of agitation of the individual molecules of the two gases are equal. This result is of great importance in the theory of heat, though we are not yet able to establish any similar result for bodies in the liquid or solid state.

In the next place, we know that in the case in which the whole pressure of the medium is due to the motion of its molecules, the pressure on unit of area is numerically equal to two-thirds of the kinetic energy in unit of volume. Hence, if equal volumes of two gases are at equal pressures the kinetic energy is the same in each. If they are also at equal temperatures the mean kinetic energy of each molecule is the same in each. If, therefore, equal volumes of two gases are at equal temperatures and pressures, the number of molecules in each is the same, and therefore, the masses of the two kinds of molecules are in the same ratio as the densities of the gases to which they belong.

This statement has been believed by chemists since the time of Gay-Lussac, who first established that the weights of the chemical equivalents of different substances are proportional to the densities of these substances when in the form of gas. The definition of the word molecule, however, as employed in the statement of Gay-Lussac's law, is by no means identical with the definition of the same word as in the kinetic theory of gases. The chemists ascertain by experiment the ratios of the masses of the different substances in a compound. From these they deduce the chemical equivalents of the different substances, that of a particular substance, say hydrogen, being taken as unity. The only evidence made use of is that furnished by chemical combinations. It is also assumed, in order to account for the facts of combination, that the reason why substances combine in definite ratios is that the molecules of the substances are in the ratio of their chemical equivalents, and that what we call combination is an action which takes place by a union of a molecule of one substance to a molecule of the other.

This kind of reasoning, when presented in a proper form and sustained by proper evidence, has a high degree of cogency. But it is purely chemical reasoning; it is not dynamical reasoning. It is founded on chemical experience, not on the laws of motion.

Our definition of a molecule is purely dynamical. A molecule is that minute portion of a substance which moves about as a whole, so that its parts, if it has any, do not part company during the motion of agitation of the gas. The result of the kinetic theory, therefore, is to give us information about the relative masses of molecules considered as moving bodies. The consistency of this information with the deductions of chemists from the phenomena of combination, greatly strengthens the evidence in favour of the actual existence and motion of gaseous molecules.

Another confirmation of the theory of molecules is derived from the experiments of Dulong and Petit on the specific heat of gases, from which they deduced the law which bears their name, and which asserts that the specific heats of equal weights of gases are inversely as their combining weights, or, in other words, that the capacities for heat of the chemical equivalents of different gases are equal. We have seen that the temperature is determined by the kinetic energy of agitation of each molecule. The molecule has also a certain amount of energy of internal motion, whether of rotation or of vibration, but the hypothesis of Clausius, that the mean value of the internal energy always bears a proportion fixed for each gas to the energy of agitation, seems highly probable and consistent with experiment. The whole kinetic energy is therefore equal to the energy of agitation multiplied by a certain factor. Thus the energy communicated to a gas by heating it is divided in a certain proportion between the energy of agitation and that of the internal motion of each molecule. For a given rise of temperature the energy of agitation, say of a million molecules, is increased by the same amount whatever be the gas. The heat spent in raising the temperature is measured by the increase of the whole kinetic energy. The thermal capacities, therefore, of equal numbers of molecules of different gases are in the ratio of the factors by which the energy of agitation must be multiplied to obtain the whole energy. As this factor appears to be nearly the same for all gases of the same degree of atomicity, Dulong and Petit's law is true for such gases.

Another result of this investigation is of considerable importance in relation to certain theories,[2] which assume the existence of æthers or rare media consisting of molecules very much smaller than those of ordinary gases. According to our result, such a medium would be neither more nor less than a gas. Supposing its molecules so small that they can penetrate between the molecules of solid substances such as glass, a so-called vacuum would be full of this rare gas at the observed temperature, and at the pressure, whatever it may be, of the ætherial medium in space. The specific heat, therefore, of the medium in the so-called vacuum will be equal to that of the same volume of any other gas at the same temperature and pressure. Now, the purpose for which this molecular æther is assumed in these theories is to act on bodies by its pressure, and for this purpose the pressure is generally assumed to be very great. Hence, according to these theories, we should find the specific heat of a so-called vacuum very considerable compared with that of a quantity of air filling the same space.

We have now made a certain definite amount of progress towards a complete molecular theory of gases. We know the mean velocity of the molecules of each gas in metres per second, and we know the relative masses of the molecules of different gases. We also know that the molecules of one and the same gas are all equal in mass. For if they

[1] *Sitzungsberichte der K. K. Akad., Wien*, 8th Oct. 1868.

[2] See Gustav Hansemann, *Die Atome und ihre Bewegungen*. 1871. (H. G. Mayer.)

are not, the method of dialysis, as employed by Graham, would enable us to separate the molecules of smaller mass from those of greater, as they would stream through porous substances with greater velocity. We should thus be able to separate a gas, say hydrogen, into two portions, having different densities and other physical properties, different combining weights, and probably different chemical properties of other kinds. As no chemist has yet obtained specimens of hydrogen differing in this way from other specimens, we conclude that all the molecules of hydrogen are of sensibly the same mass, and not merely that their mean mass is a statistical constant of great stability.

But as yet we have not considered the phenomena which enable us to form an estimate of the actual mass and dimensions of a molecule. It is to Clausius that we owe the first definite conception of the free path of a molecule and of the mean distance travelled by a molecule between successive encounters. He showed that the number of encounters of a molecule in a given time is proportional to the velocity, to the number of molecules in unit of volume, and to the square of the distance between the centres of two molecules when they act on one another so as to have an encounter. From this it appears that if we call this distance of the centres the diameter of a molecule, and the volume of a sphere having this diameter the volume of a molecule, and the sum of the volumes of all the molecules the molecular volume of the gas, then the diameter of a molecule is a certain multiple of the quantity obtained by diminishing the free path in the ratio of the molecular volume of the gas to the whole volume of the gas. The numerical value of this multiple differs slightly, according to the hypothesis we assume about the law of distribution of velocities. It also depends on the definition of an encounter. When the molecules are regarded as elastic spheres we know what is meant by an encounter, but if they act on each other at a distance by attractive or repulsive forces of finite magnitude, the distance of their centres varies during an encounter, and is not a definite quantity. Nevertheless, the above statement of Clausius enables us, if we know the length of the mean path and the molecular volume of a gas, to form a tolerably near estimate of the diameter of the sphere of the intense action of a molecule, and thence of the number of molecules in unit of volume and the actual mass of each molecule. To complete the investigation we have, therefore, to determine the mean path and the molecular volume. The first numerical estimate of the mean path of a gaseous molecule was made by the present writer from data derived from the internal friction of air. There are three phenomena which depend on the length of the free path of the molecules of a gas. It is evident that the greater the free path the more rapidly will the molecules travel from one part of the medium to another, because their direction will not be so often altered by encounters with other molecules. If the molecules in different parts of the medium are of different kinds, their progress from one part of the medium to another can be easily traced by analysing portions of the medium taken from different places. The rate of diffusion thus found furnishes one method of estimating the length of the free path of a molecule. This kind of diffusion goes on not only between the molecules of different gases, but among the molecules of the same gas, only in the latter case the results of the diffusion cannot be traced by analysis. But the diffusing molecules carry with them in their free paths the momentum and the energy which they happen at a given instant to have. The diffusion of momentum tends to equalise the apparent motion of different parts of the medium, and constitutes the phenomenon called the internal friction or viscosity of gases. The diffusion of energy tends to equalise the temperature of different parts of the medium, and constitutes the phenomenon of the conduction of heat in gases.

These three phenomena—the diffusion of matter, of motion, and of heat in gases—have been experimentally investigated,—the diffusion of matter by Graham and Loschmidt, the diffusion of motion by Oscar Meyer and Clerk Maxwell, and that of heat by Stefan.

These three kinds of experiments give results which in the present imperfect state of the theory and the extreme difficulty of the experiments, especially those on the conduction of heat, may be regarded as tolerably consistent with each other. At the pressure of our atmosphere, and at the temperature of melting ice, the mean path of a molecule of hydrogen is about the 10,000th of a millimetre, or about the fifth part of a wave-length of green light. The mean path of the molecules of other gases is shorter than that of hydrogen.

The determination of the molecular volume of a gas is subject as yet to considerable uncertainty. The most obvious method is that of compressing the gas till it assumes the liquid form. It seems probable, from the great resistance of liquids to compression, that their molecules are at about the same distance from each other as that at which two molecules of the same substance in the gaseous form act on each other during an encounter. If this is the case, the molecular volume of a gas is somewhat less than the volume of the liquid into which it would be condensed by pressure, or, in other words, the density of the molecules is somewhat greater than that of the liquid.

Now, we know the relative weights of different molecules with great accuracy, and, from a knowledge of the mean path, we can calculate their relative diameters approximately. From these we can deduce the relative densities of different kinds of molecules. The relative densities so calculated have been compared by Lorenz Meyer with the observed densities of the liquids into which the gases may be condensed, and he finds a remarkable correspondence between them. There is considerable doubt, however, as to the relation between the molecules of a liquid and those of its vapour, so that till a larger number of comparisons have been made, we must not place too much reliance on the calculated densities of molecules. Another, and perhaps a more refined, method is that adopted by M. Van der Waals, who deduces the molecular volume from the deviations of the pressure from Boyle's law as the gas is compressed.

The first numerical estimate of the diameter of a molecule was that made by Loschmidt in 1865 from the mean path and the molecular volume. Independently of him and of each other, Mr Stoney, in 1868, and Sir W. Thomson, in 1870, published results of a similar kind—those of Thomson being deduced not only in this way, but from considerations derived from the thickness of soap bubbles, and from the electric action between zinc and copper.

The diameter and the mass of a molecule, as estimated by these methods, are, of course, very small, but by no means infinitely so. About two millions of molecules of hydrogen in a row would occupy a millimetre, and about two hundred million million million of them would weigh a milligramme. These numbers must be considered as exceedingly rough guesses; they must be corrected by more extensive and accurate experiments as science advances; but the main result, which appears to be well established, is that the determination of the mass of a molecule is a legitimate object of scientific research, and that this mass is by no means immeasurably small.

Loschmidt illustrates these molecular measurements by a comparison with the smallest magnitudes visible by means of a microscope. Nobert, he tells us, can draw 4000 lines in the breadth of a millimetre. The intervals between

these lines can be observed with a good microscope. A cube, whose side is the 4000th of a millimetre, may be taken as the *minimum visibile* for observers of the present day. Such a cube would contain from 60 to 100 million molecules of oxygen or of nitrogen; but since the molecules of organised substances contain on an average about 50 of the more elementary atoms, we may assume that the smallest organised particle visible under the microscope contains about two million molecules of organic matter. At least half of every living organism consists of water, so that the smallest living being visible under the microscope does not contain more than about a million organic molecules. Some exceedingly simple organism may be supposed built up of not more than a million similar molecules. It is impossible, however, to conceive so small a number sufficient to form a being furnished with a whole system of specialised organs.

Thus molecular science sets us face to face with physiological theories. It forbids the physiologist from imagining that structural details of infinitely small dimensions can furnish an explanation of the infinite variety which exists in the properties and functions of the most minute organisms.

A microscopic germ is, we know, capable of development into a highly organised animal. Another germ, equally microscopic, becomes, when developed, an animal of a totally different kind. Do all the differences, infinite in number, which distinguish the one animal from the other, arise each from some difference in the structure of the respective germs? Even if we admit this as possible, we shall be called upon by the advocates of Pangenesis to admit still greater marvels. For the microscopic germ, according to this theory, is no mere individual, but a representative body, containing members collected from every rank of the long-drawn ramification of the ancestral tree, the number of these members being amply sufficient not only to furnish the hereditary characteristics of every organ of the body and every habit of the animal from birth to death, but also to afford a stock of latent gemmules to be passed on in an inactive state from germ to germ, till at last the ancestral peculiarity which it represents is revived in some remote descendant.

Some of the exponents of this theory of heredity have attempted to elude the difficulty of placing a whole world of wonders within a body so small and so devoid of visible structure as a germ, by using the phrase structureless germs.[1] Now, one material system can differ from another only in the configuration and motion which it has at a given instant. To explain differences of function and development of a germ without assuming differences of structure is, therefore, to admit that the properties of a germ are not those of a purely material system.

The evidence as to the nature and motion of molecules, with which we have hitherto been occupied, has been derived from experiments upon gaseous media, the smallest sensible portion of which contains millions of millions of molecules. The constancy and uniformity of the properties of the gaseous medium is the direct result of the inconceivable irregularity of the motion of agitation of its molecules. Any cause which could introduce regularity into the motion of agitation, and marshal the molecules into order and method in their evolutions, might check or even reverse that tendency to diffusion of matter, motion, and energy, which is one of the most invariable phenomena of nature, and to which Thomson has given the name of the dissipation of energy.

Thus, when a sound-wave is passing through a mass of air, this motion is of a certain definite type, and if left to itself the whole motion is passed on to other masses of air, and the sound-wave passes on, leaving the air behind it at rest. Heat, on the other hand, never passes out of a hot body except to enter a colder body, so that the energy of sound-waves, or any other form of energy which is propagated so as to pass wholly out of one portion of the medium and into another, cannot be called heat.

We have now to turn our attention to a class of molecular motions, which are as remarkable for their regularity as the motion of agitation is for its irregularity.

It has been found, by means of the spectroscope, that the light emitted by incandescent substances is different according to their state of condensation. When they are in an extremely rarefied condition the spectrum of their light consists of a set of sharply-defined bright lines. As the substance approaches a denser condition the spectrum tends to become continuous, either by the lines becoming broader and less defined, or by new lines and bands appearing between them, till the spectrum at length loses all its characteristics and becomes identical with that of solid bodies when raised to the same temperature.

Hence the vibrating systems, which are the source of the emitted light, must be vibrating in a different manner in these two cases. When the spectrum consists of a number of bright lines, the motion of the system must be compounded of a corresponding number of types of harmonic vibration.

In order that a bright line may be sharply defined, the vibratory motion which produces it must be kept up in a perfectly regular manner for some hundreds or thousands of vibrations. If the motion of each of the vibrating bodies is kept up only during a small number of vibrations, then, however regular may be the vibrations of each body while it lasts, the resultant disturbance of the luminiferous medium, when analysed by the prism, will be found to contain, besides the part due to the regular vibrations, other motions, depending on the starting and stopping of each particular vibrating body, which will become manifest as a diffused luminosity scattered over the whole length of the spectrum. A spectrum of bright lines, therefore, indicates that the vibrating bodies when set in motion are allowed to vibrate in accordance with the conditions of their internal structure for some time before they are again interfered with by external forces.

It appears, therefore, from spectroscopic evidence that each molecule of a rarefied gas is, during the greater part of its existence, at such a distance from all other molecules that it executes its vibrations in an undisturbed and regular manner. This is the same conclusion to which we were led by considerations of another kind at p. 39.

We may therefore regard the bright lines in the spectrum of a gas as the result of the vibrations executed by the molecules while describing their free paths. When two molecules separate from one another after an encounter, each of them is in a state of vibration, arising from the unequal action on different parts of the same molecule during the encounter. Hence, though the centre of mass of the molecule describing its free path moves with uniform velocity, the parts of the molecule have a vibratory motion with respect to the centre of mass of the whole molecule, and it is the disturbance of the luminiferous medium communicated to it by the vibrating molecules which constitutes the emitted light.

We may compare the vibrating molecule to a bell. When struck, the bell is set in motion. This motion is compounded of harmonic vibrations of many different periods, each of which acts on the air, producing notes of as many different pitches. As the bell communicates its motion to the air, these vibrations necessarily decay, some

[1] See F. Galton, "On Blood Relationship," *Proc. Roy. Soc.*, June 13, 1872.

of them faster than others, so that the sound contains fewer and fewer notes, till at last it is reduced to the fundamental note of the bell.[1] If we suppose that there are a great many bells precisely similar to each other, and that they are struck, first one and then another, in a perfectly irregular manner, yet so that, on an average, as many bells are struck in one second of time as in another, and also in such a way that, on an average, any one bell is not again struck till it has ceased to vibrate, then the audible result will appear a continuous sound, composed of the sound emitted by bells in all states of vibration, from the clang of the actual stroke to the final hum of the dying fundamental tone.

But now let the number of bells be reduced while the same number of strokes are given in a second. Each bell will now be struck before it has ceased to vibrate, so that in the resulting sound there will be less of the fundamental tone and more of the original clang, till at last, when the peal is reduced to one bell, on which innumerable hammers are continually plying their strokes all out of time, the sound will become a mere noise, in which no musical note can be distinguished.

In the case of a gas we have an immense number of molecules, each of which is set in vibration when it encounters another molecule, and continues to vibrate as it describes its free path. The molecule is a material system, the parts of which are connected in some definite way, and from the fact that the bright lines of the emitted light have always the same wave-lengths, we learn that the vibrations corresponding to these lines are always executed in the same periodic time, and therefore the force tending to restore any part of the molecule to its position of equilibrium in the molecule must be proportional to its displacement relative to that position.

From the mathematical theory of the motion of such a system, it appears that the whole motion may be analysed into the following parts, which may be considered each independently of the others :—In the first place, the centre of mass of the system moves with uniform velocity in a straight line. This velocity may have any value. In the second place, there may be a motion of rotation, the angular momentum of the system about its centre of mass remaining during the free path constant in magnitude and direction. This angular momentum may have any value whatever, and its axis may have any direction. In the third place, the remainder of the motion is made up of a number of component motions, each of which is an harmonic vibration of a given type. In each type of vibration the periodic time of vibration is determined by the nature of the system, and is invariable for the same system. The relative amount of motion in different parts of the system is also determinate for each type, but the absolute amount of motion and the phase of the vibration of each type are determined by the particular circumstances of the last encounter, and may vary in any manner from one encounter to another.

The values of the periodic times of the different types of vibration are given by the roots of a certain equation, the form of which depends on the nature of the connections of the system. In certain exceptionally simple cases, as, for instance, in that of a uniform string stretched between two fixed points, the roots of the equation are connected by simple arithmetical relations, and if the internal structure of a molecule had an analogous kind of simplicity, we might expect to find in the spectrum of the molecule a series of bright lines, whose wave-lengths are in simple arithmetical ratios.

But if we suppose the molecule to be constituted according to some different type, as, for instance, if it is an elastic sphere, or if it consists of a finite number of atoms kept in their places by attractive and repulsive forces, the roots of the equation will not be connected with each other by any simple relations, but each may be made to vary independently of the others by a suitable change of the connections of the system. Hence, we have no right to expect any definite numerical relations among the wave-lengths of the bright lines of a gas.

The bright lines of the spectrum of an incandescent gas are therefore due to the harmonic vibrations of the molecules of the gas during their free paths. The only effect of the motion of the centre of mass of the molecule is to alter the time of vibration of the light as received by a stationary observer. When the molecule is coming towards the observer, each successive impulse will have a shorter distance to travel before it reaches his eye, and therefore the impulses will appear to succeed each other more rapidly than if the molecule were at rest, and the contrary will be the case if the molecule is receding from the observer. The bright line corresponding to the vibration will therefore be shifted in the spectrum towards the blue end when the molecule is approaching, and towards the red end when it is receding from the observer. By observations of the displacement of certain lines in the spectrum, Dr Huggins and others have measured the rate of approach or of recession of certain stars with respect to the earth, and Mr Lockyer has determined the rate of motion of tornadoes in the sun. But Lord Rayleigh has pointed out that according to the dynamical theory of gases the molecules are moving hither and thither with so great velocity that, however narrow and sharply defined any bright line due to a single molecule may be, the displacement of the line towards the blue by the approaching molecules, and towards the red by the receding molecules, will produce a certain amount of widening and blurring of the line in the spectrum, so that there is a limit to the sharpness of definition of the lines of a gas. The widening of the lines due to this cause will be in proportion to the velocity of agitation of the molecules. It will be greatest for the molecules of smallest mass, as those of hydrogen, and it will increase with the temperature. Hence the measurement of the breadth of the hydrogen lines, such as C or F in the spectrum of the solar prominences, may furnish evidence that the temperature of the sun cannot exceed a certain value.

On the Theory of Vortex Atoms.

The equations which form the foundations of the mathematical theory of fluid motion were fully laid down by Lagrange and the great mathematicians of the end of last century, but the number of solutions of cases of fluid motion which had been actually worked out remained very small, and almost all of these belonged to a particular type of fluid motion, which has been since named the irrotational type. It had been shown, indeed, by Lagrange, that a perfect fluid, if its motion is at any time irrotational, will continue in all time coming to move in an irrotational manner, so that, by assuming that the fluid was at one time at rest, the calculation of its subsequent motion may be very much simplified.

It was reserved for Helmholtz to point out the very remarkable properties of rotational motion in a homogeneous incompressible fluid devoid of all viscosity. We must first define the physical properties of such a fluid. In the first place, it is a material substance. Its motion is

[1] Part of the energy of motion is, in the case of the bell, dissipated in the substance of the bell in virtue of the viscosity of the metal, and assumes the form of heat, but it is not necessary, for the purpose of illustration, to take this cause of the decay of vibrations into account.

continuous in space and time, and if we follow any portion of it as it moves, the mass of that portion remains invariable. These properties it shares with all material substances. In the next place, it is incompressible. The form of a given portion of the fluid may change, but its volume remains invariable; in other words, the density of the fluid remains the same during its motion. Besides this, the fluid is homogeneous, or the density of all parts of the fluid is the same. It is also continuous, so that the mass of the fluid contained within any closed surface is always *exactly* proportional to the volume contained within that surface. This is equivalent to asserting that the fluid is not made up of molecules; for, if it were, the mass would vary in a discontinuous manner as the volume increases continuously, because first one and then another molecule would be included within the closed surface. Lastly, it is a perfect fluid, or, in other words, the stress between one portion and a contiguous portion is always normal to the surface which separates these portions, and this whether the fluid is at rest or in motion.

We have seen that in a molecular fluid the interdiffusion of the molecules causes an interdiffusion of motion of different parts of the fluid, so that the action between contiguous parts is no longer normal but in a direction tending to diminish their relative motion. Hence the perfect fluid cannot be molecular.

All that is necessary in order to form a correct mathematical theory of a material system is that its properties shall be clearly defined, and shall be consistent with each other. This is essential; but whether a substance having such properties actually exists is a question which comes to be considered only when we propose to make some practical application of the results of the mathematical theory. The properties of our perfect liquid are clearly defined and consistent with each other, and from the mathematical theory we can deduce remarkable results, some of which may be illustrated in a rough way by means of fluids which are by no means perfect in the sense of not being viscous, such, for instance, as air and water.

The motion of a fluid is said to be irrotational when it is such that if a spherical portion of the fluid were suddenly solidified, the solid sphere so formed would not be rotating about any axis. When the motion of the fluid is rotational the axis and angular velocity of the rotation of any small part of the fluid are those of a *small* spherical portion suddenly solidified.

The mathematical expression of these definitions is as follows:—Let u, v, w be the components of the velocity of the fluid at the point (x, y, z), and let

$$\alpha=\frac{dv}{dz}-\frac{dw}{dy}\,,\ \beta=\frac{dw}{dx}-\frac{du}{dz}\,,\ \gamma=\frac{du}{dy}-\frac{dv}{dx} \qquad (1),$$

then α, β, γ are the components of the velocity of rotation of the fluid at the point (x, y, z). The axis of rotation is in the direction of the resultant of α, β, and γ, and the velocity of rotation, ω, is measured by this resultant.

A line drawn in the fluid, so that at every point of the line

$$\frac{1}{\alpha}\frac{dx}{ds}=\frac{1}{\beta}\frac{dy}{ds}=\frac{1}{\gamma}\frac{dz}{ds}=\frac{1}{\omega} \quad . \quad . \qquad (2),$$

where s is the length of the line up to the point x, y, z, is called a vortex line. Its direction coincides at every point with that of the axis of rotation of the fluid.

We may now prove the theorem of Helmholtz, that the points of the fluid which at any instant lie in the same vortex line continue to lie in the same vortex line during the whole motion of the fluid.

The equations of motion of a fluid are of the form

$$\rho\frac{\delta u}{\delta t}+\frac{dp}{dx}+\rho\frac{dV}{dx}=0 \quad . \quad . \qquad (3),$$

when ρ is the density, which in the case of our homogeneous incompressible fluid we may assume to be unity, the operator $\frac{\delta}{\delta t}$ represents the rate of variation of the symbol to which it is prefixed at a point which is carried forward with the fluid, so that

$$\frac{\delta u}{\delta t}=\frac{du}{dt}+u\frac{du}{dx}+v\frac{du}{dy}+w\frac{du}{dz} \quad . \quad . \qquad (4),$$

p is the pressure, and V is the potential of external forces. There are two other equations of similar form in y and z. Differentiating the equation in y with respect to z, and that in z with respect to y, and subtracting the second from the first, we find

$$\frac{d}{dz}\frac{\delta v}{\delta t}-\frac{d}{dy}\frac{\delta w}{\delta t}=0 \quad . \quad . \quad . \quad . \qquad (5).$$

Performing the differentiations and remembering equations (1) and also the condition of incompressibility,

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0 \quad . \quad . \quad . \qquad (6),$$

we find

$$\frac{\delta\alpha}{\delta t}=\alpha\frac{du}{dx}+\beta\frac{du}{dy}+\gamma\frac{du}{dz} \quad . \quad . \qquad (7).$$

Now, let us suppose a vortex line drawn in the fluid so as always to begin at the same particle of the fluid. The components of the velocity of this point are u, v, w. Let us find those of a point on the moving vortex line at a distance ds from this point where

$$ds=\omega d\sigma \quad . \quad . \quad . \qquad (8).$$

The co-ordinates of this point are

$$x+\alpha d\sigma\ ,\ y+\beta d\sigma\ ,\ z+\gamma d\sigma \quad . \quad . \qquad (9),$$

and the components of its velocity are

$$u+\frac{\delta\alpha}{\delta t}d\sigma\ ,\ v+\frac{\delta\beta}{\delta t}d\sigma\ ,\ w+\frac{\delta\gamma}{\delta t}d\sigma \quad . \qquad (10).$$

Consider the first of these components. In virtue of equation (7) we may write it

$$u+\frac{du}{dx}\alpha d\sigma+\frac{du}{dy}\beta d\sigma+\frac{du}{dz}\gamma d\sigma \quad . \quad . \qquad (11),$$

or

$$u+\frac{du}{dx}\frac{dx}{d\sigma}d\sigma+\frac{du}{dy}\frac{dy}{d\sigma}d\sigma+\frac{du}{dz}\frac{dz}{d\sigma}d\sigma \quad . \qquad (12),$$

or

$$u+\frac{du}{d\sigma}d\sigma \quad . \quad . \quad . \quad . \quad . \quad . \quad . \qquad (13).$$

But this represents the value of the component u of the velocity of the fluid itself at the same point, and the same thing may be proved of the other components.

Hence the velocity of the second point on the vortex line is identical with that of the fluid at that point. In other words, the vortex line swims along with the fluid, and is always formed of the same row of fluid particles. The vortex line is therefore no mere mathematical symbol, but has a physical existence continuous in time and space.

By differentiating equations (1) with respect to x, y, and z respectively, and adding the results, we obtain the equation—

$$\frac{d\alpha}{dx}+\frac{d\beta}{dy}+\frac{d\gamma}{dz}=0 \quad . \quad . \quad . \quad . \qquad (14).$$

This is an equation of the same form with (6), which expresses the condition of flow of a fluid of invariable density. Hence, if we imagine a fluid, quite independent of the original fluid, whose components of velocity are α, β, γ, this imaginary fluid will flow without altering its density.

Now, consider a closed curve in space, and let vortex

lines be drawn in both directions from every point of this curve. These vortex lines will form a tubular surface, which is called a vortex tube or a vortex filament. Since the imaginary fluid flows along the vortex lines without change of density, the quantity which in unit of time flows through any section of the same vortex tube must be the same. Hence, at any section of a vortex tube the product of the area of the section into the mean velocity of rotation is the same. This quantity is called the *strength* of the vortex tube.

A vortex tube cannot begin or end within the fluid; for, if it did, the imaginary fluid, whose velocity components are α, β, γ, would be generated from nothing at the beginning of the tube, and reduced to nothing at the end of it. Hence, if the tube has a beginning and an end, they must lie on the surface of the fluid mass. If the fluid is infinite the vortex tube must be infinite, or else it must return into itself.

We have thus arrived at the following remarkable theorems relating to a finite vortex tube in an infinite fluid:—(1.) It returns into itself, forming a closed ring. We may therefore describe it as a vortex *ring*. (2.) It always consists of the same portion of the fluid. Hence its volume is invariable. (3.) Its strength remains always the same. Hence the velocity of rotation at any section varies inversely as the area of that section, and that of any segment varies directly as the length of that segment. (4.) No part of the fluid which is not originally in a state of rotational motion can ever enter into that state, and no part of the fluid whose motion is rotational can ever cease to move rotationally. (5.) No vortex tube can ever pass through any other vortex tube, or through any of its own convolutions. Hence, if two vortex tubes are linked together, they can never be separated, and if a single vortex tube is knotted on itself, it can never become untied. (6.) The motion at any instant of every part of the fluid, including the vortex rings themselves, may be accurately represented by conceiving an electric current to occupy the place of each vortex ring, the strength of the current being proportional to that of the ring. The magnetic force at any point of space will then represent in direction and magnitude the velocity of the fluid at the corresponding point of the fluid.

These properties of vortex rings suggested to Sir William Thomson[1] the possibility of founding on them a new form of the atomic theory. The conditions which must be satisfied by an atom are—permanence in magnitude, capability of internal motion or vibration, and a sufficient amount of possible characteristics to account for the difference between atoms of different kinds.

The small hard body imagined by Lucretius, and adopted by Newton, was invented for the express purpose of accounting for the permanence of the properties of bodies. But it fails to account for the vibrations of a molecule as revealed by the spectroscope. We may indeed suppose the atom elastic, but this is to endow it with the very property for the explanation of which, as exhibited in aggregate bodies, the atomic constitution was originally assumed. The massive centres of force imagined by Boscovich may have more to recommend them to the mathematician, who has no scruple in supposing them to be invested with the power of attracting and repelling according to any law of the distance which it may please him to assign. Such centres of force are no doubt in their own nature indivisible, but then they are also, singly, incapable of vibration. To obtain vibrations we must imagine molecules consisting of many such centres, but, in so doing, the possibility of these centres being separated altogether is again introduced. Besides, it is in questionable scientific taste, after using atoms so freely to get rid of forces acting at sensible distances, to make the whole function of the atoms an action at insensible distances.

On the other hand, the vortex ring of Helmholtz, imagined as the true form of the atom by Thomson, satisfies more of the conditions than any atom hitherto imagined. In the first place, it is quantitatively permanent, as regards its volume and its strength,—two independent quantities. It is also qualitatively permanent as regards its degree of implication, whether "knottedness" on itself or "linkedness" with other vortex rings. At the same time, it is capable of infinite changes of form, and may execute vibrations of different periods, as we know that molecules do. And the number of essentially different implications of vortex rings may be very great without supposing the degree of implication of any of them very high.

But the greatest recommendation of this theory, from a philosophical point of view, is that its success in explaining phenomena does not depend on the ingenuity with which its contrivers "save appearances," by introducing first one hypothetical force and then another. When the vortex atom is once set in motion, all its properties are absolutely fixed and determined by the laws of motion of the primitive fluid, which are fully expressed in the fundamental equations. The disciple of Lucretius may cut and carve his solid atoms in the hope of getting them to combine into worlds; the follower of Boscovich may imagine new laws of force to meet the requirements of each new phenomenon; but he who dares to plant his feet in the path opened up by Helmholtz and Thomson has no such resources. His primitive fluid has no other properties than inertia, invariable density, and perfect mobility, and the method by which the motion of this fluid is to be traced is pure mathematical analysis. The difficulties of this method are enormous, but the glory of surmounting them would be unique.

There seems to be little doubt that an encounter between two vortex atoms would be in its general character similar to those which we have already described. Indeed, the encounter between two smoke rings in air gives a very lively illustration of the elasticity of vortex rings.

But one of the first, if not the very first desideratum in a complete theory of matter is to explain—first, mass, and second, gravitation. To explain mass may seem an absurd achievement. We generally suppose that it is of the essence of matter to be the receptacle of momentum and energy, and even Thomson, in his definition of his primitive fluid, attributes to it the possession of mass. But according to Thomson, though the primitive fluid is the only true matter, yet that which we call matter is not the primitive fluid itself, but a mode of motion of that primitive fluid. It is the mode of motion which constitutes the vortex rings, and which furnishes us with examples of that permanence and continuity of existence which we are accustomed to attribute to matter itself. The primitive fluid, the only true matter, entirely eludes our perceptions when it is not endued with the mode of motion which converts certain portions of it into vortex rings, and thus renders it molecular.

In Thomson's theory, therefore, the mass of bodies requires explanation. We have to explain the inertia of what is only a mode of motion, and inertia is a property of matter, not of modes of motion. It is true that a vortex ring at any given instant has a definite momentum and a definite energy, but to show that bodies built up of vortex rings would have such momentum and energy as we know them to have is, in the present state of the theory, a very difficult task.

It may seem hard to say of an infant theory that it is bound to explain gravitation. Since the time of Newton

[1] "On Vortex Atoms," *Proc. Roy. Soc. Edin.*, 18th February 1867.

the doctrine of gravitation has been admitted and expounded, till it has gradually acquired the character rather of an ultimate fact than of a fact to be explained.

It seems doubtful whether Lucretius considers gravitation to be an essential property of matter, as he seems to assert in the very remarkable lines—

> "Nam si tantundem est in lanæ glomere, quantum
> Corporis in plumbo est, tantundem pendere par est:
> Corporis officium est quoniam premere omnia deorsum."
> —*De Rerum Natura*, i. 361.

If this is the true opinion of Lucretius, and if the downward flight of the atoms arises, in his view, from their own gravity, it seems very doubtful whether he attributed the weight of sensible bodies to the impact of the atoms. The latter opinion is that of Le Sage, of Geneva, propounded in his *Lucrèce Newtonien*, and in his *Traité de Physique Mécanique*, published, along with a second treatise of his own, by Pierre Prevost, of Geneva, in 1818.[1] The theory of Le Sage is that the gravitation of bodies towards each other is caused by the impact of streams of atoms flying in all directions through space. These atoms he calls ultramundane corpuscules, because he conceives them to come in all directions from regions far beyond that part of the system of the world which is in any way known to us. He supposes each of them to be so small that a collision with another ultramundane corpuscule is an event of very rare occurrence. It is by striking against the molecules of gross matter that they discharge their function of drawing bodies towards each other. A body placed by itself in free space and exposed to the impacts of these corpuscules would be bandied about by them in all directions, but because, on the whole, it receives as many blows on one side as on another, it cannot thereby acquire any sensible velocity. But if there are two bodies in space, each of them will screen the other from a certain proportion of the corpuscular bombardment, so that a smaller number of corpuscules will strike either body on that side which is next the other body, while the number of corpuscules which strike it in other directions remains the same.

Each body will therefore be urged towards the other by the effect of the excess of the impacts it receives on the side furthest from the other. If we take account of the impacts of those corpuscules only which come directly from infinite space, and leave out of consideration those which have already struck mundane bodies, it is easy to calculate the result on the two bodies, supposing their dimensions small compared with the distance between them.

The force of attraction would vary directly as the product of the areas of the sections of the bodies taken normal to the distance and inversely as the square of the distance between them.

Now, the attraction of gravitation varies as the product of the *masses* of the bodies between which it acts, and inversely as the square of the distance between them. If, then, we can imagine a constitution of bodies such that the effective areas of the bodies are proportional to their masses, we shall make the two laws coincide. Here, then, seems to be a path leading towards an explanation of the law of gravitation, which, if it can be shown to be in other respects consistent with facts, may turn out to be a royal road into the very arcana of science.

Le Sage himself shows that, in order to make the effective area of a body, in virtue of which it acts as a screen to the streams of ultramundane corpuscules, proportional to the mass of the body, whether the body be large or small, we must admit that the size of the solid atoms of the body is exceedingly small compared with the distances between them, so that a very small proportion of the corpuscules are stopped even by the densest and largest bodies. We may picture to ourselves the streams of corpuscules coming in every direction, like light from a uniformly illuminated sky. We may imagine a material body to consist of a congeries of atoms at considerable distances from each other, and we may represent this by a swarm of insects flying in the air. To an observer at a distance this swarm will be visible as a slight darkening of the sky in a certain quarter. This darkening will represent the action of the material body in stopping the flight of the corpuscules. Now, if the proportion of light stopped by the swarm is very small, two such swarms will stop nearly the same amount of light, whether they are in a line with the eye or not; but if one of them stops an appreciable proportion of light, there will not be so much left to be stopped by the other, and the effect of two swarms in a line with the eye will be less than the sum of the two effects separately.

Now, we know that the effect of the attraction of the sun and earth on the moon is not appreciably different when the moon is eclipsed than on other occasions when full moon occurs without an eclipse. This shows that the number of the corpuscules which are stopped by bodies of the size and mass of the earth, and even the sun, is very small compared with the number which pass straight through the earth or the sun without striking a single molecule. To the streams of corpuscules the earth and the sun are mere systems of atoms scattered in space, which present far more openings than obstacles to their rectilinear flight.

Such is the ingenious doctrine of Le Sage, by which he endeavours to explain universal gravitation. Let us try to form some estimate of this continual bombardment of ultramundane corpuscules which is being kept up on all sides of us.

We have seen that the sun stops but a very small fraction of the corpuscules which enter it. The earth, being a smaller body, stops a still smaller proportion of them. The proportion of those which are stopped by a small body, say a 1 ℔ shot, must be smaller still in an enormous degree, because its thickness is exceedingly small compared with that of the earth.

Now, the weight of the ball, or its tendency towards the earth, is produced, according to this theory, by the excess of the impacts of the corpuscules which come from above over the impacts of those which come from below, and have passed through the earth. Either of these quantities is an exceedingly small fraction of the momentum of the whole number of corpuscules which pass through the ball in a second, and their difference is a small fraction of either, and yet it is equivalent to the weight of a pound. The velocity of the corpuscules must be enormously greater than that of any of the heavenly bodies, otherwise, as may easily be shown, they would act as a resisting medium opposing the motion of the planets. Now, the energy of a moving system is half the product of its momentum into its velocity. Hence the energy of the corpuscules, which by their impacts on the ball during one second urge it towards the earth, must be a number of foot-pounds equal to the number of feet over which a corpuscule travels in a second, that is to say, not less than thousands of millions. But this is only a small fraction of the energy of all the impacts which the atoms of the ball receive from the innumerable streams of corpuscules which fall upon it in all directions.

Hence the rate at which the energy of the corpuscules is spent in order to maintain the gravitating property of a single pound, is at least millions of millions of foot-pounds per second.

What becomes of this enormous quantity of energy? If the corpuscules, after striking the atoms, fly off with a

[1] See also *Constitution de la Matière*, &c., par le P. Leray, Paris, 1869.

velocity equal to that which they had before, they will carry their energy away with them into the ultramundane regions. But if this be the case, then the corpuscules rebounding from the body in any given direction will be both in number and in velocity exactly equivalent to those which are prevented from proceeding in that direction by being deflected by the body, and it may be shown that this will be the case whatever be the shape of the body, and however many bodies may be present in the field. Thus, the rebounding corpuscules exactly make up for those which are deflected by the body, and there will be no excess of the impacts on any other body in one direction or another.

The explanation of gravitation, therefore, falls to the ground if the corpuscules are like perfectly elastic spheres, and rebound with a velocity of separation equal to that of approach. If, on the other hand, they rebound with a smaller velocity, the effect of attraction between the bodies will no doubt be produced, but then we have to find what becomes of the energy which the molecules have brought with them but have not carried away.

If any appreciable fraction of this energy is communicated to the body in the form of heat, the amount of heat so generated would in a few seconds raise it, and in like manner the whole material universe, to a white heat.

It has been suggested by Sir W. Thomson that the corpuscules may be so constructed so to carry off their energy with them, provided that part of their kinetic energy is transformed, during impact, from energy of translation to energy of rotation or vibration. For this purpose the corpuscules must be material systems, not mere points. Thomson suggests that they are vortex atoms, which are set into a state of vibration at impact, and go off with a smaller velocity of translation, but in a state of violent vibration. He has also suggested the possibility of the vortex corpuscule regaining its swiftness and losing part of its vibratory agitation by communion with its kindred corpuscules in infinite space.

We have devoted more space to this theory than it seems to deserve, because it is ingenious, and because it is the only theory of the cause of gravitation which has been so far developed as to be capable of being attacked and defended. It does not appear to us that it can account for the temperature of bodies remaining moderate while their atoms are exposed to the bombardment. The temperature of bodies must tend to approach that at which the average kinetic energy of a molecule of the body would be equal to the average kinetic energy of an ultramundane corpuscule.

Now, suppose a plane surface to exist which stops *all* the corpuscules. The pressure on this plane will be $p = \text{N}\text{M}u^2$ where M is the mass of a corpuscule, N the number in unit of volume, and u its velocity normal to the plane. Now, we know that the very greatest pressure existing in the universe must be much less than the pressure p, which would be exerted against a body which stops all the corpuscules. We are also tolerably certain that N, the number of corpuscules which are at any one time within unit of volume, is small compared with the value of N for the molecules of ordinary bodies. Hence, $\text{M}u^2$ must be enormous compared with the corresponding quantity for ordinary bodies, and it follows that the impact of the corpuscules would raise all bodies to an enormous temperature. We may also observe that according to this theory the habitable universe, which we are accustomed to regard as the scene of a magnificent illustration of the conservation of energy as the fundamental principle of all nature, is in reality maintained in working order only by an enormous expenditure of external power, which would be nothing less than ruinous if the supply were drawn from anywhere else than from the infinitude of space, and which, if the contrivances of the most eminent mathematicians should be found in any respect defective, might at any moment tear the whole universe atom from atom.

We must now leave these speculations about the nature of molecules and the cause of gravitation, and contemplate the material universe as made up of molecules. Every molecule, so far as we know, belongs to one of a definite number of species. The list of chemical elements may be taken as representing the known species which have been examined in the laboratories. Several of these have been discovered by means of the spectroscope, and more may yet remain to be discovered in the same way. The spectroscope has also been applied to analyse the light of the sun, the brighter stars, and some of the nebulæ and comets, and has shown that the character of the light emitted by these bodies is similar in some cases to that emitted by terrestrial molecules, and in others to light from which the molecules have absorbed certain rays. In this way a considerable number of coincidences have been traced between the systems of lines belonging to particular terrestrial substances and corresponding lines in the spectra of the heavenly bodies.

The value of the evidence furnished by such coincidences may be estimated by considering the degree of accuracy with which one such coincidence may be observed. The interval between the two lines which form Fraunhöfer's line D is about the five hundredth part of the interval between B and G on Kirchhoff's scale. A discordance between the positions of two lines amounting to the tenth part of this interval, that is to say, the five thousandth part of the length of the bright part of the spectrum, would be very perceptible in a spectroscope of moderate power. We may define the power of the spectroscope to be the number of times which the smallest measurable interval is contained in the length of the visible spectrum. Let us denote this by p. In the case we have supposed p will be about 5000.

If the spectrum of the sun contains n lines of a certain degree of intensity, the probability that any one line of the spectrum of a gas will coincide with one of these n lines is

$$1 - \left(1 - \frac{1}{p}\right) = \frac{n}{p}\left(1 - \frac{n-1}{2}\frac{1}{p} + \text{\&c.}\right),$$

and when p is large compared with n, this becomes nearly $\frac{n}{p}$. If there are r lines in the spectrum of the gas, the probability that each and every one shall coincide with a line in the solar spectrum is approximately $\frac{n^r}{p^r}$. Hence, in the case of a gas whose spectrum contains several lines, we have to compare the results of two hypotheses. If a large amount of the gas exists in the sun, we have the strongest reason for expecting to find all the r lines in the solar spectrum. If it does not exist, the probability that r lines out of the n observed lines shall coincide with the lines of the gas is exceedingly small. If, then, we find all the r lines in their proper places in the solar spectrum, we have very strong grounds for believing that the gas exists in the sun. The probability that the gas exists in the sun is greatly strengthened if the character of the lines as to relative intensity and breadth is found to correspond in the two spectra.

The absence of one or more lines of the gas in the solar spectrum tends of course to weaken the probability, but the amount to be deducted from the probability must depend on what we know of the variation in the relative intensity of the lines when the temperature and the pressure of the gas are made to vary.

Coincidences observed, in the case of several terrestrial substances, with several systems of lines in the spectra of the heavenly bodies, tend to increase the evidence for the

doctrine that terrestrial substances exist in the heavenly bodies, while the discovery of particular lines in a celestial spectrum which do not coincide with any line in a terrestrial spectrum does not much weaken the general argument, but rather indicates either that a substance exists in the heavenly body not yet detected by chemists on earth, or that the temperature of the heavenly body is such that some substance, undecomposable by our methods, is there split up into components unknown to us in their separate state.

We are thus led to believe that in widely-separated parts of the visible universe molecules exist of various kinds, the molecules of each kind having their various periods of vibration either identical, or so nearly identical that our spectroscopes cannot distinguish them. We might argue from this that these molecules are alike in all other respects, as, for instance, in mass. But it is sufficient for our present purpose to observe that the same kind of molecule, say that of hydrogen, has the same set of periods of vibration, whether we procure the hydrogen from water, from coal, or from meteoric iron, and that light, having the same set of periods of vibration, comes to us from the sun, from Sirius, and from Arcturus.

The same kind of reasoning which led us to believe that hydrogen exists in the sun and stars, also leads us to believe that the molecules of hydrogen in all these bodies had a common origin. For a material system capable of vibration may have for its periods of vibration any set of values whatever. The probability, therefore, that two material systems, quite independent of each other, shall have, to the degree of accuracy of modern spectroscopic measurements, the same set of periods of vibration, is so very small that we are forced to believe that the two systems are not independent of each other. When, instead of two such systems, we have innumerable multitudes all having the same set of periods, the argument is immensely strengthened.

Admitting, then, that there is a real relation between any two molecules of hydrogen, let us consider what this relation may be.

We may conceive of a mutual action between one body and another tending to assimilate them. Two clocks, for instance, will keep time with each other if connected by a wooden rod, though they have different rates if they were disconnected. But even if the properties of a molecule were as capable of modification as those of a clock, there is no physical connection of a sufficient kind between Sirius and Arcturus.

There are also methods by which a large number of bodies differing from each other may be sorted into sets, so that those in each set more or less resemble each other. In the manufacture of small shot this is done by making the shot roll down an inclined plane. The largest specimens acquire the greatest velocities, and are projected farther than the smaller ones. In this way the various pellets, which differ both in size and in roundness, are sorted into different kinds, those belonging to each kind being nearly of the same size, and those which are not tolerably spherical being rejected altogether.

If the molecules were originally as various as these leaden pellets, and were afterwards sorted into kinds, we should have to account for the disappearance of all the molecules which did not fall under one of the very limited number of kinds known to us; and to get rid of a number of indestructible bodies, exceeding by far the number of the molecules of all the recognised kinds, would be one of the severest labours ever proposed to a cosmogonist.

It is well known that living beings may be grouped into a certain number of species, defined with more or less precision, and that it is difficult or impossible to find a series of individuals forming the links of a continuous chain between one species and another. In the case of living beings, however, the generation of individuals is always going on, each individual differing more or less from its parents. Each individual during its whole life is undergoing modification, and it either survives and propagates its species, or dies early, accordingly as it is more or less adapted to the circumstances of its environment. Hence, it has been found possible to frame a theory of the distribution of organisms into species by means of generation, variation, and discriminative destruction. But a theory of evolution of this kind cannot be applied to the case of molecules, for the individual molecules neither are born nor die, they have neither parents nor offspring, and so far from being modified by their environment, we find that two molecules of the same kind, say of hydrogen, have the same properties, though one has been compounded with carbon and buried in the earth as coal for untold ages, while the other has been "occluded" in the iron of a meteorite, and after unknown wanderings in the heavens has at last fallen into the hands of some terrestrial chemist.

The process by which the molecules become distributed into distinct species is not one of which we know any instances going on at present, or of which we have as yet been able to form any mental representation. If we suppose that the molecules known to us are built up each of some moderate number of atoms, these atoms being all of them exactly alike, then we may attribute the limited number of molecular species to the limited number of ways in which the primitive atoms may be combined so as to form a permanent system.

But though this hypothesis gets rid of the difficulty of accounting for the independent origin of different species of molecules, it merely transfers the difficulty from the known molecules to the primitive atoms. How did the atoms come to be all alike in those properties which are in themselves capable of assuming any value?

If we adopt the theory of Boscovich, and assert that the primitive atom is a mere centre of force, having a certain definite mass, we may get over the difficulty about the equality of the mass of all atoms by laying it down as a doctrine which cannot be disproved by experiment, that mass is not a quantity capable of continuous increase or diminution, but that it is in its own nature discontinuous, like number, the atom being the unit, and all masses being multiples of that unit. We have no evidence that it is possible for the ratio of two masses to be an incommensurable quantity, for the incommensurable quantities in geometry are supposed to be traced out in a continuous medium. If matter is atomic, and therefore discontinuous, it is unfitted for the construction of perfect geometrical models, but in other respects it may fulfil its functions.

But even if we adopt a theory which makes the equality of the mass of different atoms a result depending on the nature of mass rather than on any quantitative adjustment, the correspondence of the periods of vibration of actual molecules is a fact of a different order.

We know that radiations exist having periods of vibration of every value between those corresponding to the limits of the visible spectrum, and probably far beyond these limits on both sides. The most powerful spectroscope can detect no gap or discontinuity in the spectrum of the light emitted by incandescent lime.

The period of vibration of a luminous particle is therefore a quantity which in itself is capable of assuming any one of a series of values, which, if not mathematically continuous, is such that consecutive observed values differ from each other by less than the ten thousandth part of either. There is, therefore, nothing in the nature of time itself to prevent the period of vibration of a molecule from assuming any one of many thousand different observable

values. That which determines the period of any particular kind of vibration is the relation which subsists between the corresponding type of displacement and the force of restitution thereby called into play, a relation involving constants of space and time as well as of mass.

It is the equality of these space- and time-constants for all molecules of the same kind which we have next to consider. We have seen that the very different circumstances in which different molecules of the same kind have been placed have not, even in the course of many ages, produced any appreciable difference in the values of these constants. If, then, the various processes of nature to which these molecules have been subjected since the world began have not been able in all that time to produce any appreciable difference between the constants of one molecule and those of another, we are forced to conclude that it is not to the operation of any of these processes that the uniformity of the constants is due.

The formation of the molecule is therefore an event not belonging to that order of nature under which we live. It is an operation of a kind which is not, so far as we are aware, going on on earth or in the sun or the stars, either now or since these bodies began to be formed. It must be referred to the epoch, not of the formation of the earth or of the solar system, but of the establishment of the existing order of nature, and till not only these worlds and systems, but the very order of nature itself is dissolved, we have no reason to expect the occurrence of any operation of a similar kind.

In the present state of science, therefore, we have strong reasons for believing that in a molecule, or if not in a molecule, in one of its component atoms, we have something which has existed either from eternity or at least from times anterior to the existing order of nature. But besides this atom, there are immense numbers of other atoms of the same kind, and the constants of each of these atoms are incapable of adjustment by any process now in action. Each is physically independent of all the others.

Whether or not the conception of a multitude of beings existing from all eternity is in itself self-contradictory, the conception becomes palpably absurd when we attribute a relation of quantitative equality to all these beings. We are then forced to look beyond them to some common cause or common origin to explain why this singular relation of equality exists, rather than any one of the infinite number of possible relations of inequality.

Science is incompetent to reason upon the creation of matter itself out of nothing. We have reached the utmost limit of our thinking faculties when we have admitted that, because matter cannot be eternal and self-existent, it must have been created. It is only when we contemplate not matter in itself, but the form in which it actually exists, that our mind finds something on which it can lay hold.

That matter, as such, should have certain fundamental properties, that it should have a continuous existence in space and time, that all action should be between two portions of matter, and so on, are truths which may, for aught we know, be of the kind which metaphysicians call necessary. We may use our knowledge of such truths for purposes of deduction, but we have no data for speculating on their origin.

But the equality of the constants of the molecules is a fact of a very different order. It arises from a particular distribution of matter, a *collocation*, to use the expression of Dr Chalmers, of things which we have no difficulty in imagining to have been arranged otherwise. But many of the ordinary instances of collocation are adjustments of constants, which are not only arbitrary in their own nature, but in which variations actually occur; and when it is pointed out that these adjustments are beneficial to living beings, and are therefore instances of benevolent design, it is replied that those variations which are not conducive to the growth and multiplication of living beings tend to their destruction, and to the removal thereby of the evidence of any adjustment not beneficial.

The constitution of an atom, however, is such as to render it, so far as we can judge, independent of all the dangers arising from the struggle for existence. Plausible reasons may, no doubt, be assigned for believing that if the constants had varied from atom to atom through any sensible range, the bodies formed by aggregates of such atoms would not have been so well fitted for the construction of the world as the bodies which actually exist. But as we have no experience of bodies formed of such variable atoms this must remain a bare conjecture.

Atoms have been compared by Sir J. Herschel to manufactured articles, on account of their uniformity. The uniformity of manufactured articles may be traced to very different motives on the part of the manufacturer. In certain cases it is found to be less expensive as regards trouble, as well as cost, to make a great many objects exactly alike than to adapt each to its special requirements. Thus, shoes for soldiers are made in large numbers without any designed adaptation to the feet of particular men. In another class of cases the uniformity is intentional, and is designed to make the manufactured article more valuable. Thus, Whitworth's bolts are made in a certain number of sizes, so that if one bolt is lost, another may be got at once, and accurately fitted to its place. The identity of the arrangement of the words in the different copies of a document or book is a matter of great practical importance, and it is more perfectly secured by the process of printing than by that of manuscript copying.

In a third class not a part only but the whole of the value of the object arises from its exact conformity to a given standard. Weights and measures belong to this class, and the existence of many well-adjusted material standards of weight and measure in any country furnishes evidence of the existence of a system of law regulating the transactions of the inhabitants, and enjoining in all professed measures a conformity to the national standard.

There are thus three kinds of usefulness in manufactured articles—cheapness, serviceableness, and quantitative accuracy. Which of these was present to the mind of Sir J. Herschel we cannot now positively affirm, but it was at least as likely to have been the last as the first, though it seems more probable that he meant to assert that a number of exactly similar things cannot be each of them eternal and self-existent, and must therefore have been made, and that he used the phrase "manufactured article" to suggest the idea of their being made in great numbers.

(J. C. M.)

ATOOI, one of the larger Sandwich Islands, in the North Pacific Ocean. Towards the N.E. and N.W. the country is rugged and broken, but to the southward it is more level. The hills rise from the sea with a gentle acclivity, and, at a little distance back, are covered with wood; the central peaks attain an elevation of 7000 feet. The chief ports are Waimea and Hanalei. The island was one of the stations chosen for the observation of the transit of Venus in 1874. It is nearly 40 miles in length, and contains about 10,000 inhabitants. Long. 159° 40′ W., lat. 21° 57′ N.

ATRATO, a river of Colombia, South America, which,

after a course of 250 miles, almost due N., for the most part through a low and swampy region, falls into the Gulf of Uraba or Darien. The gold and platinum mines of Choco were on some of its affluents, and its sands are still auriferous. The river has attracted considerable attention in connection with schemes for the construction of a ship-canal across the isthmus. It is navigable for small vessels for about 140 miles.

ATREK or Attruck, a river which rises in the mountains of Khorasan, and flows W. along the borders of Persia and the Russian possessions, till it falls in the south-eastern corner of the Caspian, a short distance to the N. of Ashurada.

ATREUS, in *Greek Legend*, a son of Pelops, had, with his brother Thyestes, settled in Mycenæ, where he succeeded Eurystheus in the sovereignty, in which he was secured by the possession of a lamb or ram with a golden fleece. His wife Aërope, a daughter of Minos, bribed by Thyestes, assisted the latter to carry off the ram. But Zeus, in the interest of Atreus, wrought a miracle, causing the sun which before had risen in the west to rise in the east. Thyestes was driven from Mycenæ, but returned to his brother begging to be forgiven. Atreus, appearing to welcome him, invited him to a banquet to eat of his own son, whom he had slain. From this crime followed the ills which befell Agamemnon, the son of Atreus (Æschylus, *Agam.* 1583, *foll.*).

ATRI or Atria, the ancient *Hadria*, a town of Naples, in the province of Abruzzo Ulteriore I., situated on a steep mountain 5 miles from the Adriatic, and 18 miles S.E. of Teramo. It is the see of a bishop, and has a cathedral, a parish church, and several convents and hospitals. It contains 9877 inhabitants. Remains of the ancient city have been discovered to the S. of the present site, consisting of the ruins of a theatre and baths, with pavements, and vases of Greek manufacture. It was a very flourishing commercial port at an early period, but had declined into a small town in the time of Strabo. Its modern revival has been furthered by the excavation of new canals.

ATRIUM, the principal apartment in a Roman house, was entered through the *ostium* or *janua*, which opened off the *vestibulum*, a clear space between the middle of the house and the street, formed by the projection of the two sides. It was generally quadrangular in shape, and was roofed all over, with the exception of a square opening, called *compluvium*, towards which the roofs sloped, and by which the rain-water was conducted down to a basin (*impluvium*) fixed in the floor. The opening in the roof seems sometimes to have been called *impluvium* (Terence, *Eun.*, iii. 5; *Phorm.*, iv. 4). In the early periods of Roman civilisation, the atrium was the common public apartment, and was used for the reception of visitors and clients, and for ordinary domestic purposes, as cooking and dining. In it were placed the ancestral pictures, the marriage-couch, the *focus*, or hearth, and generally a small altar. Here, too, were kept the looms at which the mistress of the house sat and span with her maid-servants. At a somewhat later period, and among the wealthy, separate apartments were built for kitchens and dining-rooms, and the atrium was kept as a general reception-room for clients and visitors. It appears sometimes to have been called *cavædium*, but the relation of these two is somewhat obscure. According to some authorities, the *cavædium* was simply the open space formed when the impluvium was surrounded with pillars to support the roof; according to others, the *cavædium* was really the principal room, to which the atrium served as an antechamber.

Atrium, in *Ecclesiastical Antiquities*, denotes an open place or court before a church. It consisted of a large area or square plat of ground, surrounded with a portico or cloister, situated between the porch or vestibule and the body of the church. In the centre was placed a fountain, wherein the worshippers washed their hands before entering church. In the atrium those who were not suffered to advance farther, and more particularly the first class of penitents, stood to solicit the prayers of the faithful as they went into the church. It was also used as a burying ground, at first only for distinguished persons, but afterwards for all believers.

ATROPHY (α priv., τροφή, nourishment), a term in medicine used to describe a state of wasting due to some interference with the function of healthy nutrition. In the living organism there are ever at work changes involving the waste of its component tissues, which render necessary, in order to the preservation of life, the supply and proper assimilation of nutritive material. It is also essential for the maintenance of health that a due relation exist between these processes of waste and repair, so that the one may not be in excess of the other. When the appropriation of nutriment exceeds the waste, hypertrophy or increase in bulk of the tissues takes place. (See Hypertrophy.) When, on the other hand, the supply of nutritive matter is suspended or diminished, or when the power of assimilation is impaired, atrophy or wasting is the result. Thus the whole body becomes atrophied in many diseases; and in old age every part of the frame, with the single exception of the heart, undergoes atrophic change. Atrophy may, however, affect single organs or parts of the body, irrespective of the general state of nutrition, and this may be brought about in a variety of ways. One of the most frequently observed of such instances is atrophy from disuse, or cessation of function. Thus, when a limb is deprived of the natural power of motion, either by paralysis or by painful joint disease, the condition of exercise essential to its nutrition being no longer fulfilled, atrophy of all its textures sooner or later takes place. The brain in imbeciles is frequently observed to be shrivelled, and in many cases of blindness there is atrophy of the optic nerve and optic tract. This form of atrophy is likewise well exemplified in the case of those organs and structures of the body which subserve important ends during fœtal life, but which, ceasing to be necessary after birth, undergo a sort of natural atrophy, such as the thymus gland, and certain vessels specially concerned in the fœtal circulation. The uterus after parturition undergoes a certain amount of atrophy, and the ovaries, after the child-bearing period, become shrunken. Atrophy of a part may also be caused by interruption to its normal blood supply, as in the case of the ligature or obstruction of an artery. Again, long standing disease, by affecting the nutrition of an organ and by inducing the deposit of morbid products, may result in atrophy, as frequently happens in affections of the liver and kidneys. Parts that are subjected to continuous pressure are liable to become atrophied, as is sometimes seen in internal organs which have been pressed upon by tumours or other morbid growths, and is well illustrated in the case of the feet of Chinese ladies, which are prevented from growing by persistent compression exercised from birth. Atrophy may manifest itself simply by loss of substance; but, on the other hand, it is often found to co-exist with degenerative changes in the textures affected and the formation of adventitious growth, so that the part may not be reduced in bulk although atrophied as regards its proper structure. Thus, in the case of the heart, when affected with fatty degeneration, there is atrophy of the proper muscular texture, which, however, being largely replaced by fatty matter, the organ may undergo no diminution in volume, but may, on the contrary, be increased in size. Atrophy is usually a gradual and slow process, but sometimes it proceeds rapidly. In the disease known by the

name of *acute yellow atrophy of the liver*, that organ undergoes such rapidly destructive change as results in its shrinking to half, or one-third, of its normal size in the course of a few days.

The term *progressive muscular atrophy* (synonyms, *wasting* or *creeping palsy*) is applied to an affection of the muscular system, which is characterised by the atrophy and subsequent paralysis of certain muscles, or groups of muscles, and is associated with morbid changes in the anterior roots of the nerves of the spinal cord. This disease begins insidiously, and is often first observed to affect the muscles of one hand, generally the right. The attention of the sufferer is first attracted by the power of the hand becoming weakened, and then there is found to be a wasting of certain of its muscles, particularly those of the ball of the thumb. Gradually other muscles in the arms and legs become affected in a similar manner, their atrophy being attended with a corresponding diminution in power. Although sometimes arrested, this disease tends to progress, involving additional muscles, until in course of time the greater part of the muscular system is implicated, and a fatal result ensues. (J. O. A.)

ATROPOS (α priv., and τρέπειν, to turn), the eldest of the three Moirai, Parcæ, or Fates. Her name, The Unalterable, indicates the part generally played by her, viz., that of rendering the decisions of her sisters irreversible or immutable. This is the function ascribed to her by Plato (*Rep.*, x. 620), who also assigns to her supremacy over future events (617). Ancient authorities, however, are not unanimous in their distribution of the parts of the three sisters. Atropos is most frequently represented with scales, a sun-dial, or a cutting instrument, the "abhorred shears," with which she slits the thin-spun thread of life that has been placed on the spindle by Clotho and drawn off by Lachesis. See PARCÆ.

ATTACHMENT, in *English Law*, is a process from a court of record, awarded by the justices at their discretion, on a bare suggestion, or on their own knowledge, and is properly grantable in cases of contempt. It differs from arrest, in that he who arrests a man carries him to a person of higher power to be forthwith disposed of; but he that attaches keeps the party attached, and presents him in court at the day assigned, as appears by the words of the writ. Another difference is, that arrest is only upon the body of a man, whereas an attachment is often upon his goods. It is distinguished from distress in not extending to lands, as the latter does; nor does a distress touch the body, as an attachment does. Every court of record has power to fine and imprison for contempt of its authority. Attachment being merely a process to bring the defendant before the court, is not necessary in cases of contempt in the presence of the court itself. Attachment will be granted against peers and members of Parliament, only for such gross contempts as rescues, disobedience to the Queen's writs, and the like. Attachment will not lie against a corporation. The County Courts in this respect are regulated by the 9 and 10 Vict. c. 95, § 113, and the 12 and 13 Vict. c. 101, § 2. They can only punish for contempts committed in presence of the court. (See CONTEMPT OF COURT.) Attachments are granted on a rule in the first instance to show cause, which must be personally served before it can be made absolute, except for non-payment of costs on a master's allocatur, and against a sheriff for not obeying a rule to return a writ or to bring in the body. The offender is then arrested, and when committed will be compelled to answer interrogatories, exhibited against him by the party at whose instance the proceedings have been had; and the examination when taken is referred to the master, who reports thereon, and on the contempt being reported, the court gives judgment according to its discretion, in the same manner as upon a conviction for a misdemeanour at common law. Sir W. Blackstone observes that "this method of making the defendant answer upon oath to a criminal charge is not agreeable to the genius of the common law in any other instance," and it may be added that the elasticity of the legal definitions of contempt of court, especially with respect to comments on judicial proceedings, is the subject of much complaint.

ATTACHMENT OUT OF CHANCERY enforced answers and obedience to decrees and orders of that court, now merged in the High Court of Justice under the Judicature Act, 1873, and was made out without order upon an affidavit of the due service of the process, &c., with whose requirements compliance was sought. A corporation, however, is proceeded against by distringas and not by attachment. It was formerly competent to the plaintiff to compel the appearance of a defendant in Chancery by attachment, but the usual course was to enter appearance for him in case of default. By the proposed rules under the Judicature Act, 1873, a writ of attachment is to have the same force and effect as the old attachment out of Chancery. It is one of the modes of execution allowed for the recovery of property other than land or money.

ATTACHMENT OF THE FOREST is the proceeding in the Courts of Attachments, Woodmote, or Forty Days' Courts. These courts have now fallen into absolute desuetude. They were held before the verderers of the royal forests in different parts of the kingdom once in every forty days, for the purpose of inquiring into all offences against "vert and venison." The attachment is by the bodies of the offenders, if taken in the very act of killing venison, or stealing wood, or preparing so to do, or by fresh and immediate pursuit after the act is done; else they must be attached by their goods. These attachments were received by the verderers and enrolled, and certified under their seals to the Court of Justice seat, or Sweinmote, which formed the two superior of the forest courts.

ATTACHMENT, FOREIGN, is an important custom prevailing in the city of London, whereby a creditor may attach money owing to his debtor, or property belonging to him in the possession of third parties. The person holding the property or owing the money must be within the city at the time of being served with the process, but all persons are entitled to the benefit of the custom. The plaintiff having commenced his action, and made a satisfactory affidavit of his debt, is entitled to issue attachment, which thereupon affects all the money or property of the defendant in the hands of the third party, who in these proceedings is called the *garnishee*. The garnishee, of course, has as against the attachment all the defences which would be available to him against the defendant, his alleged creditor. The garnishee may plead payment under the attachment, if there has been no fraud or collusion, in bar to an action by the defendant for his debt or property. The court to which this process belongs is the Mayor's Court of London, the procedure in which is regulated by 20 and 21 Vict. c. 157. This custom, and all proceedings relating thereto, are expressly exempted from the operation of the Debtor's Act, 1869. Similar customs exist in Bristol and a few other towns in England, and also in Scotland. See ARREST and ARRESTMENT.

ATTACHMENT OF DEBTS.—It was suggested by the common law commissioners in 1853 that a remedy analogous to that of Foreign Attachment might be made available to creditors, after judgment, against debts due to their debtors. Accordingly, the Common Law Procedure Act, 1854, enacted that any creditor, having obtained judgment in the superior courts, should have an order that

the judgment debtor might be examined as to any debts due and owing to him before a master of the court. On affidavit that the judgment was still unsatisfied, and that any other person within the jurisdiction was indebted to the judgment debtor, the judge was empowered to attach all debts due from such third person (called the *garnishee*) to the judgment debtor, to answer the judgment debt. This order binds the debts in the hands of the garnishee, and if he does not dispute his liability execution issues against him at once. If he disputes his liability the question must be tried. Payment by the garnishee or execution against him is a complete discharge as against the judgment debtor. These provisions were, by an order in Council of 18th Nov. 1867, extended to the County Courts. (By 33 and 34 Vict. c. 30, it is enacted that no order for the attachment of the wages of any servant, labourer, or workman shall be made by the judge of any court of record or inferior court.) The proposed rules and regulations under the Judicature Act, 1873, retain the process for attachment of debts as established by the Procedure Act of 1854.

ATTAINDER, in the *Law of England*, was the immediate and inseparable consequence from the common law upon the sentence of death. When it was clear beyond all dispute that the criminal was no longer fit to live, he was called *attaint*, *attinctus*, stained or blackened, and could not, before the 6 and 7 Vict. c. 85, § 1, be a witness in any court. This attainder took place after judgment of death, or upon such circumstances as were equivalent to judgment of death, such as judgment of outlawry on a capital crime, pronounced for absconding from justice. Conviction without judgment was not followed by attainder. The consequences of attainder were—1*st*, Forfeiture; 2*d*, Corruption of blood. On attainder for treason, the criminal forfeited to the Crown his lands, rights of entry on lands, and any interest he might have in lands for his own life or a term of years. For murder, the offender forfeited to the Crown the profit of his freeholds during life, and in the case of lands held in fee-simple, the lands themselves for a year and a day; subject to this, the lands escheated to the lord of the fee. These forfeitures related back to the time of the offence committed. Forfeitures of goods and chattels ensued not only on attainder, but on conviction for a felony of any kind, or on flight from justice, and had no relation backwards to the time of the offence committed. By *corruption of blood*, "both upwards and downwards," the attainted person could neither inherit nor transmit lands. The lands escheated to the lord of the fee, subject to the Crown's right of forfeiture. The doctrine of attainder has, however, ceased to be of much importance. By the 33 and 34 Vict. c. 23, it is enacted that henceforth no confession, verdict, inquest, conviction, or judgment of or for any treason or felony, or *felo de se*, shall cause any attainder or corruption of blood, or any forfeiture or escheat. Sentence of death, penal servitude, or imprisonment with hard labour for more than twelve months, after conviction for treason or felony, disqualifies from holding or retaining a seat in Parliament, public offices under the Crown or otherwise, right to vote at elections, &c., and such disability is to remain until the punishment has been suffered or a pardon obtained. Provision is made for the due administration of convicts' estates, in the interests of themselves and their families. Forfeiture consequent on outlawry is exempted from the provisions of the Act.

Bills of Attainder in Parliament ordinarily commence in the House of Lords; the proceedings are the same as on other bills, but the parties affected by them may appear by counsel and witnesses in both Houses. In the case of an impeachment, the House of Commons is prosecutor and the House of Lords judge; but proceedings by Bill of Attainder are *legislative* in form, and the consent of Crown, Lords, and Commons is therefore necessary.

ATTALIA, an ancient city of Pamphylia, which derived its name from Attalus II., king of Pergamus. It seems to have been a place of considerable importance, and is most probably to be identified with the modern Adalia, Antalia, or Sataliah, as it is variously called. See SATALIAH.

ATTAR, or OTTO, of ROSES, a well-known perfume of great strength, is an essential oil of roses, prepared chiefly in Hindustan and Persia. See OILS and PERFUMERY.

ATTENTION, in *Psychology*, may be defined as the concentration of consciousness, or the direction of mental energy upon a definite object or objects. By means of it we either bring within the circle of our conscious life perceptions and ideas which would not otherwise have risen from their obscurity, or render clearer and more distinct some of those already under notice. Its mode of operation and the effects produced by it may be compared with the concentration of visual activity on some definite part of the field of vision, and the clearer perception of the limited portion which is thereby attained. In both cases the result is brought about, not by effecting any change in the perceptions themselves, but simply by isolating them, and considering them to the exclusion of all other objects. Since all consciousness involves discrimination, *i.e.*, isolation of one object from others, it involves attention, which might therefore be defined as the necessary condition of consciousness. Such a definition is, however, too general, and throws no light upon the nature of the process whereby our mental energy is strengthened in particular cases. This increase of force, when consciousness is directed to any one object to the exclusion of others, is partly to be explained by reference to the general law that, as the amount of intellectual energy at our disposal is limited, the greater the number of objects over which it is spread, the less will each receive, *pluribus intentus, minor est ad singula sensus*; and conversely, the greater the concentration, the fewer must be the objects attended to. In addition to this general law of limitation, there are special circumstances which determine the amount of consciousness we shall bestow on any object. In the first place, there are certain mechanical influences only partly subject to the will, such are the force or vividness of the impression, the interest attaching to an object, the trains of associated ideas excited, or the emotions roused by its contemplation. There is, secondly, an exercise of volition employed in fixing the mind upon some definite object; this is a purely voluntary act, which can be strengthened by habit, is variable in different individuals, and to which, as being its highest stage, the name Attention is sometimes restricted. The general law of the limitation of conscious activity, pointed out above, throws considerable light on the nature of abstraction and its relation to Attention. It is clear that concentration of consciousness upon any one attribute or attributes of an object involves withdrawal of consciousness from all other attributes. This withdrawal is, logically and etymologically, Abstraction, which is thus the negative side of Attention, or, as Hamilton expresses it, the two processes form the negative and positive poles of the same mental act.

ATTERBOM, PER DANIEL AMADEUS, a Swedish poet, was born in Ostergöthland in 1790, studied in the University of Upsala from 1805 to 1815, became Professor of Philosophy there in 1828, and died in 1855. He was the leader in the great romantic movement which revolutionised Swedish literature. In 1807, when in his 17th year, he founded at Upsala an artistic society, called the Aurora League, the members of which included Palmblad, Elgström, Hedborn, and other youths, whose names were destined to

take a foremost rank in the belles-lettres of their generation. Their first newspaper, *Polyxem*, was a crude effort, soon abandoned, but in 1810 there began to appear a journal, *Fosforus*, edited by Atterbom, which lasted for a considerable time, and finds a place in classic Swedish literature. It consisted entirely of poetry and æsthetico-polemical essays; it introduced the study of the newly-arisen Romantic school of Germany, and formed a vehicle for the early works, not of Atterbom only, but of Hammarsköld, Dahlgren, Palmblad, and other eminent poets. Among Atterbom's independent works the most celebrated is *Lycksalighetens ö* (*The Fortunate Island*), a romantic drama of extraordinary beauty, published in 1823. Before this he had published a cycle of lyrics, *The Flowers*, of a mystical character, somewhat in the manner of Novalis. Of a great drama, *Fogel blå* (*The Blue Bird*), only a fragment is preserved, but what exists is among the most exquisite of his writings. As a purely lyrical poet he has not been excelled in Sweden, but his popularity has been endangered, partly by his weakness for allegory and symbolism, partly by his consistent adoption of the mannerisms of Tieck and Novalis. His renown during his lifetime was unbounded.

ATTERBURY, Francis, a man who holds a conspicuous place in the political, ecclesiastical, and literary history of England, was born in the year 1662, at Middleton in Buckinghamshire, a parish of which his father was rector. Francis was educated at Westminster School, and carried thence to Christ Church a stock of learning which, though really scanty, he through life exhibited with such judicious ostentation that superficial observers believed his attainments to be immense. At Oxford, his parts, his taste, and his bold, contemptuous, and imperious spirit soon made him conspicuous. Here he published, at twenty, his first work, a translation of the noble poem of *Absalom and Ahithophel* into Latin verse. Neither the style nor the versification of the young scholar was that of the Augustan age. In English composition he succeeded much better. In 1687 he distinguished himself among many able men who wrote in defence of the Church of England, then persecuted by James II., and calumniated by apostates who had for lucre quitted her communion. Among these apostates none was more active or malignant than Obadiah Walker, who was master of University College, and who had set up there, under the royal patronage, a press for printing tracts against the established religion. In one of these tracts, written apparently by Walker himself, many aspersions were thrown on Martin Luther. Atterbury undertook to defend the great Saxon Reformer, and performed that task in a manner singularly characteristic. Whoever examines his reply to Walker will be struck by the contrast between the feebleness of those parts which are argumentative and defensive, and the vigour of those parts which are rhetorical and aggressive. The Papists were so much galled by the sarcasms and invectives of the young polemic, that they raised a cry of treason, and accused him of having, by implication, called King James a Judas.

After the Revolution, Atterbury, though bred in the doctrines of non-resistance and passive obedience, readily swore fealty to the new Government. In no long time he took holy orders. He occasionally preached in London with an eloquence which raised his reputation, and soon had the honour of being appointed one of the royal chaplains. But he ordinarily resided at Oxford, where he took an active part in academical business, directed the classical studies of the undergraduates of his college, and was the chief adviser and assistant of Dean Aldrich, a divine now chiefly remembered by his catches, but renowned among his contemporaries as a scholar, a Tory, and a High-Churchman. It was the practice, not a very judicious practice, of Aldrich, to employ the most promising youths of his college in editing Greek and Latin books. Among the studious and well-disposed lads who were, unfortunately for themselves, induced to become teachers of philology when they should have been content to be learners, was Charles Boyle, son of the earl of Orrery, and nephew of Robert Boyle, the great experimental philosopher. The task assigned to Charles Boyle was to prepare a new edition of one of the most worthless books in existence. It was a fashion among those Greeks and Romans who cultivated rhetoric as an art, to compose epistles and harangues in the names of eminent men. Some of these counterfeits are fabricated with such exquisite taste and skill, that it is the highest achievement of criticism to distinguish them from originals. Others are so feebly and rudely executed, that they can hardly impose on an intelligent schoolboy. The best specimen which has come down to us is perhaps the *Oration for Marcellus*, such an imitation of Tully's eloquence as Tully would himself have read with wonder and delight. The worst specimen is perhaps a collection of letters purporting to have been written by that Phalaris who governed Agrigentum more than 500 years before the Christian era. The evidence, both internal and external, against the genuineness of these letters is overwhelming. When, in the 15th century, they emerged, in company with much that was far more valuable, from their obscurity, they were pronounced spurious by Politian, the greatest scholar of Italy, and by Erasmus, the greatest scholar on our side of the Alps. In truth, it would be as easy to persuade an educated Englishman, that one of Johnson's *Ramblers* was the work of William Wallace, as to persuade a man like Erasmus, that a pedantic exercise, composed in the trim and artificial Attic of the time of Julian, was a despatch written by a crafty and ferocious Dorian, who roasted people alive many years before there existed a volume of prose in the Greek language. But though Christ Church could boast of many good Latinists, of many good English writers, and of a greater number of clever and fashionable men of the world than belonged to any other academic body, there was not then in the college a single man capable of distinguishing between the infancy and the dotage of Greek literature. So superficial, indeed, was the learning of the rulers of this celebrated society, that they were charmed by an essay which Sir William Temple published in praise of the ancient writers. It now seems strange, that even the eminent public services, the deserved popularity, and the graceful style of Temple, should have saved so silly a performance from universal contempt. Of the books which he most vehemently eulogised, his eulogies proved that he knew nothing. In fact, he could not read a line of the language in which they were written. Among many other foolish things, he said that the letters of Phalaris were the oldest letters and also the best in the world. Whatever Temple wrote attracted notice. People who had never heard of the *Epistles of Phalaris* began to inquire about them. Aldrich, who knew very little Greek, took the word of Temple who knew none, and desired Boyle to prepare a new edition of these admirable compositions which, having long slept in obscurity, had become on a sudden objects of general interest.

The edition was prepared with the help of Atterbury, who was Boyle's tutor, and of some other members of the college. It was an edition such as might be expected from people who would stoop to edit such a book. The notes were worthy of the text; the Latin version worthy of the Greek original. The volume would have been forgotten in a month, had not a misunderstanding about a manuscript arisen between the young editor and the

greatest scholar that had appeared in Europe since the revival of letters, Richard Bentley. The manuscript was in Bentley's keeping. Boyle wished it to be collated. A mischief-making bookseller informed him that Bentley had refused to lend it, which was false, and also that Bentley had spoken contemptuously of the letters attributed to Phalaris, and of the critics who were taken in by such counterfeits, which was perfectly true. Boyle, much provoked, paid, in his preface, a bitterly ironical compliment to Bentley's courtesy. Bentley revenged himself by a short dissertation, in which he proved that the epistles were spurious, and the new edition of them worthless; but he treated Boyle personally with civility as a young gentleman of great hopes, whose love of learning was highly commendable, and who deserved to have had better instructors.

Few things in literary history are more extraordinary than the storm which this little dissertation raised. Bentley had treated Boyle with forbearance; but he had treated Christ Church with contempt; and the Christ Churchmen, wherever dispersed, were as much attached to their college as a Scotchman to his country, or a Jesuit to his order. Their influence was great. They were dominant at Oxford, powerful in the Inns of Court and in the College of Physicians, conspicuous in Parliament and in the literary and fashionable circles of London. Their unanimous cry was that the honour of the college must be vindicated, that the insolent Cambridge pedant must be put down. Poor Boyle was unequal to the task, and disinclined to it. It was, therefore, assigned to his tutor Atterbury.

The answer to Bentley, which bears the name of Boyle, but which was, in truth, no more the work of Boyle than the letters to which the controversy related were the work of Phalaris, is now read only by the curious, and will in all probability never be reprinted again. But it had its day of noisy popularity. It was to be found not only in the studies of men of letters, but on the tables of the most brilliant drawing-rooms of Soho Square and Covent Garden. Even the beaux and coquettes of that age, the Wildairs and the Lady Lurewells, the Mirabells, and the Millamants, congratulated each other on the way in which the gay young gentleman, whose erudition sate so easily upon him, and who wrote with so much pleasantry and good breeding about the Attic dialect and the anapæstic measure, Sicilian talents and Thericlean cups, had bantered the queer prig of a doctor. Nor was the applause of the multitude undeserved. The book is, indeed, Atterbury's masterpiece, and gives a higher notion of his powers than any of those works to which he put his name. That he was altogether in the wrong on the main question, and on all the collateral questions springing out of it, that his knowledge of the language, the literature, and the history of Greece, was not equal to what many freshmen now bring up every year to Cambridge and Oxford, and that some of his blunders seem rather to deserve a flogging than a refutation, is true; and therefore it is that his performance is, in the highest degree, interesting and valuable to a judicious reader. It is good by reason of its exceeding badness. It is the most extraordinary instance that exists of the art of making much show with little substance. There is no difficulty, says the steward of Molière's miser, in giving a fine dinner with plenty of money: the really great cook is he who can set out a banquet with no money at all. That Bentley should have written excellently on ancient chronology and geography, on the development of the Greek language, and the origin of the Greek drama, is not strange. But that Atterbury should, during some years, have been thought to have treated these subjects much better than Bentley, is strange indeed. It is true that the champion of Christ Church had all the help which the most celebrated members of that society could give him. Smalridge contributed some very good wit; Friend and others some very bad archæology and philology. But the greater part of the volume was entirely Atterbury's: what was not his own was revised and retouched by him; and the whole bears the mark of his mind—a mind inexhaustibly rich in all the resources of controversy, and familiar with all the artifices which make falsehood look like truth, and ignorance like knowledge. He had little gold; but he beat that little out to the very thinnest leaf, and spread it over so vast a surface, that to those who judged by a glance, and who did not resort to balances and tests, the glittering heap of worthless matter which he produced seemed to be an inestimable treasure of massy bullion. Such arguments as he had he placed in the clearest light. Where he had no arguments, he resorted to personalities, sometimes serious, generally ludicrous, always clever and cutting. But, whether he was grave or merry, whether he reasoned or sneered, his style was always pure, polished, and easy.

Party spirit then ran high; yet though Bentley ranked among Whigs, and Christ Church was a stronghold of Toryism, Whigs joined with Tories in applauding Atterbury's volume. Garth insulted Bentley, and extolled Boyle in lines which are now never quoted except to be laughed at. Swift, in his *Battle of the Books*, introduced with much pleasantry Boyle, clad in armour, the gift of all the gods, and directed by Apollo in the form of a human friend, for whose name a blank is left which may easily be filled up. The youth, so accoutred and so assisted, gains an easy victory over his uncourteous and boastful antagonist. Bentley, meanwhile, was supported by the consciousness of an immeasurable superiority, and encouraged by the voices of the few who were really competent to judge the combat. "No man," he said, justly and nobly, "was ever written down but by himself." He spent two years in preparing a reply, which will never cease to be read and prized while the literature of ancient Greece is studied in any part of the world. This reply proved not only that the letters ascribed to Phalaris were spurious, but that Atterbury, with all his wit, his eloquence, his skill in controversial fence, was the most audacious pretender that ever wrote about what he did not understand. But to Atterbury this exposure was matter of indifference. He was now engaged in a dispute about matters far more important and exciting than the laws of Zaleucus and the laws of Charondas. The rage of religious factions was extreme. High Church and Low Church divided the nation. The great majority of the clergy were on the High Church side; the majority of King William's bishops were inclined to latitudinarianism. A dispute arose between the two parties touching the extent of the powers of the Lower House of Convocation. Atterbury thrust himself eagerly into the front rank of the High Churchmen. Those who take a comprehensive and impartial view of his whole career will not be disposed to give him credit for religious zeal. But it was his nature to be vehement and pugnacious in the cause of every fraternity of which he was a member. He had defended the genuineness of a spurious book simply because Christ Church had put forth an edition of that book; he now stood up for the clergy against the civil power, simply because he was a clergyman, and for the priests against the episcopal order, simply because he was as yet only a priest. He asserted the pretensions of the class to which he belonged in several treatises written with much wit, ingenuity, audacity, and acrimony. In this, as in his first controversy, he was opposed to antagonists whose knowledge of the subject in dispute was far superior to his; but in this, as in his first controversy, he imposed on the multitude by bold assertion,

by sarcasm, by declamation, and, above all, by his peculiar knack of exhibiting a little erudition in such a manner as to make it look like a great deal. Having passed himself off on the world as a greater master of classical learning than Bentley, he now passed himself off as a greater master of ecclesiastical learning than Wake or Gibson. By the great body of the clergy he was regarded as the ablest and most intrepid tribune that had ever defended their rights against the oligarchy of prelates. The Lower House of Convocation voted him thanks for his services; the University of Oxford created him a doctor of divinity; and soon after the accession of Anne, while the Tories still had the chief weight in the Government, he was promoted to the deanery of Carlisle.

Soon after he had obtained this preferment the Whig party rose to ascendency in the state. From that party he could expect no favour. Six years elapsed before a change of fortune took place. At length, in the year 1710, the prosecution of Sacheverell produced a formidable explosion of High Church fanaticism. At such a moment Atterbury could not fail to be conspicuous. His inordinate zeal for the body to which he belonged, his turbulent and aspiring temper, his rare talents for agitation and for controversy, were again signally displayed. He bore a chief part in framing that artful and eloquent speech which the accused divine pronounced at the bar of the Lords, and which presents a singular contrast to the absurd and scurrilous sermon which had very unwisely been honoured with impeachment. During the troubled and anxious months which followed the trial, Atterbury was among the most active of those pamphleteers who inflamed the nation against the Whig ministry and the Whig Parliament. When the ministry had been changed and the Parliament dissolved, rewards were showered upon him. The Lower House of Convocation elected him prolocutor. The Queen appointed him dean of Christ Church on the death of his old friend and patron Aldrich. The college would have preferred a gentler ruler. Nevertheless, the new head was received with every mark of honour. A congratulatory oration in Latin was addressed to him in the magnificent vestibule of the hall; and he in reply professed the warmest attachment to the venerable house in which he had been educated, and paid many gracious compliments to those over whom he was to preside. But it was not in his nature to be a mild or an equitable governor. He had left the chapter of Carlisle distracted by quarrels. He found Christ Church at peace; but in three months his despotic and contentious temper did at Christ Church what it had done at Carlisle. He was succeeded in both his deaneries by the humane and accomplished Smalridge, who gently complained of the state in which both had been left. "Atterbury goes before, and sets everything on fire. I come after him with a bucket of water." It was said by Atterbury's enemies that he was made a bishop because he was so bad a dean. Under his administration Christ Church was in confusion, scandalous altercations took place, opprobrious words were exchanged; and there was reason to fear that the great Tory college would be ruined by the tyranny of the great Tory doctor. He was soon removed to the bishopric of Rochester, which was then always united with the deanery of Westminster. Still higher dignities seemed to be before him. For, though there were many able men on the Episcopal bench, there were none who equalled or approached him in parliamentary talents. Had his party continued in power it is not improbable that he would have been raised to the archbishopric of Canterbury. The more splendid his prospects the more reason he had to dread the accession of a family which was well known to be partial to the Whigs. There is every reason to believe that he was one of those politicians who hoped that they might be able, during the life of Anne, to prepare matters in such a way that at her decease there might be little difficulty in setting aside the Act of Settlement and placing the Pretender on the throne. Her sudden death confounded the projects of these conspirators. Atterbury, who wanted no kind of courage, implored his confederates to proclaim James III., and offered to accompany the heralds in lawn sleeves. But he found even the bravest soldiers of his party irresolute, and exclaimed, not, it is said, without interjections which ill became the mouth of a father of the church, that the best of all causes and the most precious of all moments had been pusillanimously thrown away. He acquiesced in what he could not prevent, took the oaths to the House of Hanover, and at the coronation officiated with the outward show of zeal, and did his best to ingratiate himself with the royal family. But his servility was requited with cold contempt. No creature is so revengeful as a proud man who has humbled himself in vain. Atterbury became the most factious and pertinacious of all the opponents of the Government. In the House of Lords his oratory, lucid, pointed, lively, and set off with every grace of pronunciation and of gesture, extorted the attention and admiration even of a hostile majority. Some of the most remarkable protests which appear in the journals of the peers were drawn up by him; and, in some of the bitterest of those pamphlets which called on the English to stand up for their country against the aliens who had come from beyond the seas to oppress and plunder her, critics easily detected his style. When the rebellion of 1715 broke out, he refused to sign the paper in which the bishops of the province of Canterbury declared their attachment to the Protestant succession. He busied himself in electioneering, especially at Westminster, where as dean he possessed great influence; and was, indeed, strongly suspected of having once set on a riotous mob to prevent his Whig fellow-citizens from polling.

After having been long in indirect communication with the exiled family, he, in 1717, began to correspond directly with the Pretender. The first letter of the correspondence is extant. In that letter Atterbury boasts of having, during many years past, neglected no opportunity of serving the Jacobite cause. "My daily prayer," he says, "is that you may have success. May I live to see that day, and live no longer than I do what is in my power to forward it." It is to be remembered that he who wrote thus was a man bound to set to the church of which he was overseer an example of strict probity; that he had repeatedly sworn allegiance to the House of Brunswick; that he had assisted in placing the crown on the head of George I.; and that he had abjured James III., "without equivocation or mental reservation, on the true faith of a Christian."

It is agreeable to turn from his public to his private life. His turbulent spirit, wearied with faction and treason, now and then required repose, and found it in domestic endearments, and in the society of the most illustrious of the living and of the dead. Of his wife little is known; but between him and his daughter there was an affection singularly close and tender. The gentleness of his manners when he was in the company of a few friends was such as seemed hardly credible to those who knew him only by his writings and speeches. The charm of his "softer hour" has been commemorated by one of those friends in imperishable verse. Though Atterbury's classical attainments were not great, his taste in English literature was excellent; and his admiration of genius was so strong that it overpowered even his political and religious antipathies. His fondness for Milton, the mortal enemy of the Stuarts and of the church, was such as to

many Tories seemed a crime. On the sad night on which Addison was laid in the chapel of Henry VII., the Westminster boys remarked that Atterbury read the funeral service with a peculiar tenderness and solemnity. The favourite companions, however, of the great Tory prelate were, as might have been expected, men whose politics had at least a tinge of Toryism. He lived on friendly terms with Swift, Arbuthnot, and Gay. With Prior he had a close intimacy, which some misunderstanding about public affairs at last dissolved. Pope found in Atterbury not only a warm admirer, but a most faithful, fearless, and judicious adviser. The poet was a frequent guest at the episcopal palace among the elms of Bromley, and entertained not the slightest suspicion that his host, now declining in years, confined to an easy chair by gout, and apparently devoted to literature, was deeply concerned in criminal and perilous designs against the Government.

The spirit of the Jacobites had been cowed by the events of 1715. It revived in 1721. The failure of the South Sea project, the panic in the money market, the downfall of great commercial houses, the distress from which no part of the kingdom was exempt, had produced general discontent. It seemed not improbable that at such a moment an insurrection might be successful. An insurrection was planned. The streets of London were to be barricaded; the Tower and the Bank were to be surprised; King George, his family, and his chief captains and councillors were to be arrested, and King James was to be proclaimed. The design became known to the duke of Orleans, regent of France, who was on terms of friendship with the house of Hanover. He put the English Government on its guard. Some of the chief malcontents were committed to prison; and among them was Atterbury. No bishop of the Church of England had been taken into custody since that memorable day when the applauses and prayers of all London had followed the seven bishops to the gate of the Tower. The Opposition entertained some hope that it might be possible to excite among the people an enthusiasm resembling that of their fathers, who rushed into the waters of the Thames to implore the blessing of Sancroft. Pictures of the heroic confessor in his cell were exhibited at the shop windows. Verses in his praise were sung about the streets. The restraints by which he was prevented from communicating with his accomplices were represented as cruelties worthy of the dungeons of the Inquisition. Strong appeals were made to the priesthood. Would they tamely permit so gross an insult to be offered to their cloth? Would they suffer the ablest, the most eloquent member of their profession, the man who had so often stood up for their rights against the civil power, to be treated like the vilest of mankind? There was considerable excitement; but it was allayed by a temperate and artful letter to the clergy, the work, in all probability, of Bishop Gibson, who stood high in the favour of Walpole, and shortly after became minister for ecclesiastical affairs.

Atterbury remained in close confinement during some months. He had carried on his correspondence with the exiled family so cautiously that the circumstantial proofs of his guilt, though sufficient to produce entire moral conviction, were not sufficient to justify legal conviction. He could be reached only by a bill of pains and penalties. Such a bill the Whig party, then decidedly predominant in both Houses, was quite prepared to support. Many hot-headed members of that party were eager to follow the precedent which had been set in the case of Sir John Fenwick, and to pass an act for cutting off the bishop's head. Cadogan, who commanded the army, a brave soldier, but a headstrong politician, is said to have exclaimed with great vehemence, "Fling him to the lions in the Tower" But the wiser and more humane Walpole was always unwilling to shed blood, and his influence prevailed. When Parliament met, the evidence against the bishop was laid before committees of both Houses. Those committees reported that his guilt was proved. In the Commons a resolution pronouncing him a traitor was carried by nearly two to one. A bill was then introduced which provided that he should be deprived of his spiritual dignities, that he should be banished for life, and that no British subject should hold any intercourse with him except by the royal permission. This bill passed the Commons with little difficulty; for the bishop, though invited to defend himself, chose to reserve his defence for the assembly of which he was a member. In the Lords the contest was sharp. The young duke of Wharton, distinguished by his parts, his dissoluteness, and his versatility, spoke for Atterbury with great effect; and Atterbury's own voice was heard for the last time by that unfriendly audience which had so often listened to him with mingled aversion and delight. He produced few witnesses, nor did those witnesses say much that could be of service to him. Among them was Pope. He was called to prove that, while he was an inmate of the palace at Bromley, the bishop's time was completely occupied by literary and domestic matters, and that no leisure was left for plotting. But Pope, who was quite unaccustomed to speak in public, lost his head, and, as he afterwards owned, though he had only ten words to say, made two or three blunders.

The bill finally passed the Lords by eighty-three votes to forty-three. The bishops, with a single exception, were in the majority. Their conduct drew on them a sharp taunt from Lord Bathurst, a warm friend of Atterbury and a zealous Tory. "The wild Indians," he said, "give no quarter, because they believe that they shall inherit the skill and prowess of every adversary whom they destroy. Perhaps the animosity of the right reverend prelates to their brother may be explained in the same way."

Atterbury took leave of those whom he loved with a dignity and tenderness worthy of a better man. Three fine lines of his favourite poet were often in his mouth—

> "Some natural tears he dropped, but wiped them soon:
> The world was all before him, where to chuse
> His place of rest, and Providence his guide."

At parting he presented Pope with a Bible, and said, with a disingenuousness of which no man who had studied the Bible to much purpose would have been guilty, "If ever you learn that I have any dealings with the Pretender, I give you leave to say that my punishment is just." Pope at this time really believed the bishop to be an injured man. Arbuthnot seems to have been of the same opinion. Swift, a few months later, ridiculed with great bitterness, in the *Voyage to Laputa*, the evidence which had satisfied the two Houses of Parliament. Soon, however, the most partial friends of the banished prelate ceased to assert his innocence, and contented themselves with lamenting and excusing what they could not defend. After a short stay at Brussels he had taken up his abode at Paris, and had become the leading man among the Jacobite refugees who had assembled there. He was invited to Rome by the Pretender, who then held his mock court under the immediate protection of the Pope. But Atterbury felt that a bishop of the Church of England would be strangely out of place at the Vatican, and declined the invitation. During some months, however, he might flatter himself that he stood high in the good graces of James. The correspondence between the master and the servant was constant. Atterbury's merits were warmly acknowledged, his advice was respectfully received, and he was, as Bolingbroke had been before him, the prime minister of a king without a kingdom.

But the new favourite found, as Bolingbroke had found before him, that it was quite as hard to keep the shadow of power under a vagrant and mendicant prince as to keep the reality of power at Westminster. Though James had neither territories nor revenues, neither army nor navy, there was more faction and more intrigue among his courtiers than among those of his successful rival. Atterbury soon perceived that his counsels were disregarded, if not distrusted. His proud spirit was deeply wounded. He quitted Paris, fixed his residence at Montpellier, gave up politics, and devoted himself entirely to letters. In the sixth year of his exile he had so severe an illness that his daughter, herself in very delicate health, determined to run all risks that she might see him once more. Having obtained a licence from the English Government, she went by sea to Bordeaux, but landed there in such a state that she could travel only by boat or in a litter. Her father, in spite of his infirmities, set out from Montpellier to meet her; and she, with the impatience which is often the sign of approaching death, hastened towards him. Those who were about her in vain implored her to travel slowly. She said that every hour was precious, that she only wished to see her papa and to die. She met him at Toulouse, embraced him, received from his hand the sacred bread and wine, and thanked God that they had passed one day in each other's society before they parted for ever. She died that night.

It was some time before even the strong mind of Atterbury recovered from this cruel blow. As soon as he was himself again he became eager for action and conflict; for grief, which disposes gentle natures to retirement, to inaction, and to meditation, only makes restless spirits more restless. The Pretender, dull and bigoted as he was, had found out that he had not acted wisely in parting with one who, though a heretic, was, in abilities and accomplishments, the foremost man of the Jacobite party. The bishop was courted back, and was without much difficulty induced to return to Paris, and to become once more the phantom minister of a phantom monarchy. But his long and troubled life was drawing to a close. To the last, however, his intellect retained all its keenness and vigour. He learned, in the ninth year of his banishment, that he had been accused by Oldmixon, as dishonest and malignant a scribbler as any that has been saved from oblivion by the Dunciad, of having, in concert with other Christ Churchmen, garbled Clarendon's *History of the Rebellion*. The charge, as respected Atterbury, had not the slightest foundation; for he was not one of the editors of the *History*, and never saw it till it was printed. He published a short vindication of himself, which is a model in its kind, luminous, temperate, and dignified. A copy of this little work he sent to the Pretender, with a letter singularly eloquent and graceful. It was impossible, the old man said, that he should write anything on such a subject without being reminded of the resemblance between his own fate and that of Clarendon. They were the only two English subjects that had ever been banished from their country and debarred from all communication with their friends by Act of Parliament. But here the resemblance ended. One of the exiles had been so happy to bear a chief part in the restoration of the royal house. All that the other could now do was to die asserting the rights of that house to the last. A few weeks after this letter was written Atterbury died. He had just completed his seventieth year.

His body was brought to England, and laid, with great privacy, under the nave of Westminster Abbey. Only three mourners followed the coffin. No inscription marks the grave. That the epitaph with which Pope honoured the memory of his friend does not appear on the walls of the great national cemetery is no subject of regret, for nothing worse was ever written by Colley Cibber.

Those who wish for more complete information about Atterbury may easily collect it from his sermons and his controversial writings, from the report of the parliamentary proceedings against him, which will be found in the *State Trials*; from the five volumes of his correspondence, edited by Mr Nichols, and from the first volume of the Stuart papers, edited by Mr Glover. A very indulgent but a very interesting account of the bishop's political career will be found in Lord Stanhope's valuable *History of England*. (M.)

ATTICA, the most famous district of ancient Greece, is a triangular piece of ground projecting in a south-easterly direction into the Ægean Sea, the base line being formed by the continuous chain of Mounts Cithæron and Parnes, the apex by the promontory of Sunium. It is washed on

Sketch Map of Attica.

two sides by the sea, and this feature seems to have given rise to the name; for, notwithstanding the unusual letter-change, Ἀττική probably stands for Ἀκτική, since Strabo and other ancient writers inform us that the country originally bore both this name and that of Ἀκτή. The latter designation was frequently used by the Greeks to describe an extensive tract reaching into the sea, especially when, as in the case of Attica and the Argolic Acte, it was joined to the continent by a broad base. The coast is broken up into numerous small bights and harbours, which, however, are with few exceptions exposed to the south wind; the irregularity of the outline accounts for its great length in comparison of the superficial area of the country. The surface of Attica, as of the rest of Greece, is very mountainous, and between the mountain chains lie several plains of no great size, open on one side to the sea. On the west its natural boundary is the Corinthian Gulf, so that it would include the district of Megaris; and, as a matter of fact, before the Dorian invasion, which resulted in the foundation of Megara, the whole of this country was politically one, being in the hands of the Ionian race. This is proved by the column which, as we learn from Strabo, once stood on the Isthmus of Corinth, bearing on one side the inscription, "This land is Peloponnesus, not Ionia"—

τάδ' ἐστὶ Πελοπόννησος, οὐκ Ἰωνία—

and on the other, "This land is not Peloponnesus, but Ionia"—

τάδ' οὐχὶ Πελοπόννησος, ἀλλ' Ἰωνία.

Central position.

The central position of Attica in Greece was one main cause of its historical importance. When K. O. Müller compares Greece to a body, whose members are different in form, while a mutual connection and dependence naturally exist between them, he speaks of Attica as one of the extremities which served as the active instruments of the body of Greece, and by which it was kept in constant connection with other countries. Hence in part arose the maritime character of its inhabitants; and when they had once taken to the sea, the string of neighbouring islands, Ceos, Cythnos, and others, some of which lay within sight of their coasts, and from one to another of which it was possible to sail without losing sight of land, served to tempt them on to further enterprises. Similarly on land, the post it occupied between Northern Greece and the Peloponnese materially influenced its relation to other states, both in respect of its alliances, such as that with Thessaly, towards which country it was drawn by mutual hostility to Bœotia, which lay between them,—a friendship of great service to Athens, because it brought to her aid the Thessalian cavalry, an arm with which she herself was feebly provided; and also in respect of offensive combinations of other powers, as that between Thebes and Sparta, which throughout an important part of Greek history were closely associated in their politics, through mutual dread of their powerful neighbour.

Mountains.

The mountains of Attica, which form its most characteristic feature, are to be regarded as a continuation of that chain which, starting from Mount Tymphrestus at the southern extremity of Pindus, passes through Phocis and Bœotia under the well-known names of Parnassus and Helicon; from this proceeds the range which, as Cithæron in its western and Parnes in its eastern portion, separates Attica from Bœotia, throwing off spurs southward towards the Saronic Gulf in Ægaleos and Hymettus, which bound the plain of Athens. Again, the eastern extremity of Parnes is joined by another line of hills, which, separating from Mount Œta, skirts the Euboic Gulf, and, after entering Attica, throws up the lofty pyramid of Pentelicus, overlooking the plain of Marathon, and then sinks towards the sea at Sunium to rise once more in the outlying islands. Finally, at the extreme west of the whole district, Cithæron is bent round at right angles in the direction of the isthmus, at the northern approach to which it abuts against the mighty mass of Mount Geraneia, which is interposed between the Corinthian and the Saronic Gulf. The elevation reached by some of these is considerable, both Cithæron and Parnes being about 4600 feet, Hymettus 3360, and Pentelicus 2560, while Ægaleos does not rise higher than 1536 feet. At the present day they are extremely bare, and, to one who is accustomed to Italian scenery, their severity is apt at first to be almost repellent; but after a time the eye is delighted with the delicacy of the outlines, the minute articulation of the minor ridges and valleys, and the symmetrical way in which nature has grouped the several mountains so as to form a balance between them. The appearance thus produced can be best described as classical.

Soil.

The soil of Attica is light and thin, and requires very careful agriculture to develop its produce. This feature belongs not only to the rocky mountain sides, but to some extent also to the maritime plains, and had considerable influence on the development of the inhabitants, both by enforcing industrious habits, and in leading them at an early period to take to the sea. Still, the level ground was sufficiently fertile to form a marked contrast to the rest of the district, and this fact is represented in the mythical genealogy of the early kings, which embodies several geographical features. Thus, while first we find the name of Actæus or Actæon, who represents the ἀκτή or sea-coast, later on occurs Cranaus, a personification of the rocky ground, whence both Pindar and Aristophanes apply the epithet κρανααί to Athens; and further we meet with Erichthonius, whose name is intended to express the fruitful plains. Thucydides attributes to the nature of the thin soil (i. 2, τὸ λεπτόγεων), which presented no attraction to invaders, the permanence of the same inhabitants in the country, whence arose the claim to indigenousness on which the Athenians so greatly prided themselves; while at the same time the richer ground fostered that fondness for country life, which is proved by the enthusiastic terms in which it is always spoken of by Aristophanes, and by the discontent of the people of Attica at being forced to betake themselves to the city at the commencement of the Peloponnesian War. That we are not justified in judging of the ancient condition of the soil by the aridity which prevails at the present day, is shown by the fact that out of the 174 demes into which Attica was divided, at least one-tenth were named from trees or plants.

Climate.

But whatever drawbacks the people of Attica experienced in respect of the soil were more than compensated by the fineness of the climate. In this point they enjoyed a great advantage over their neighbours the Bœotians; and while at the present day travellers speak of the excessive heat in summer and cold in winter which they have experienced in Bœotia, Attica has always been famous for its mildness. In approaching this district from the north, a change of temperature is felt as soon as a person descends from Cithæron or Parnes, and the sea breeze, which in modern times is called ὁ ἐμβάτης, or that which sets towards shore, moderates the heat in summer. Both the Attic comedians and Plato speak with enthusiasm of their native climate, and the fineness of the Athenian intellect was attributed to the clearness of the Attic atmosphere. It was in the neighbourhood of Athens itself that the air was thought to be purest. This is what Euripides refers to in the well-known passage where he describes the inhabitants as "ever walking gracefully through the most luminous æther" (*Med.*, 829); and Milton, who is always an admirable exponent of Greek literature, in like manner says—

> "Where, on the Ægean shore, a city stands,
> Built nobly, pure the air, and light the soil,—
> Athens, the eye of Greece."

Thus it is hardly hyperbole in Xenophon to say "one would not err in thinking that this city is placed near the centre of Greece—nay, of the civilised world,—because, the farther removed persons are from it, the severer is the cold or heat they meet with" (*Vectigal.*, i. 6). To the clearness of the atmosphere must be referred the distinctness with which distant objects can be discerned, for from the Acropolis the lines of white marble that streak the sides of Pentelicus are visible, and also the brilliant colouring which is so conspicuous in an Athenian sunset. Thus Dean Stanley speaks of "the flood of fire with which the marble columns, the mountains, and the sea are all bathed and penetrated;" "the violet hue which Hymettus assumes in the evening sky, in contrast to the glowing furnace of the rock of Lycabettus, and the rosy pyramid of Pentelicus." And M. Bursian says—"Amongst the most beautiful natural scenes that I have beheld I reckon the sight of Hymettus from Athens at sunset, whilst the entire range, as soon as the sun begins to sink, quivers with the loveliest rosy red, which gradually passes through the most varied gradations into the deepest violet. No one who has not enjoyed this spectacle can understand the *purpureos colles florentis Hymetti* of Ovid." This otherwise perfect climate is slightly marred by the prevalence of the north wind. This is expressed on the Horologium of Antonius Cyrrhestes, called the Temple or Tower of the Winds, at

Athens, where Boreas is represented as a bearded man of stern aspect, thickly clad, and wearing strong buskins; he blows into a conch shell, which he holds in his hand as a sign of his tempestuous character. This also explains the close connection between him and this country in mythology, especially in the legend of Orithyia, who is the daughter of the Cephisus, thus representing the mists that rise from the streams, and whom he carries off with him and makes his wife. One of their offspring is called Chione, or the Snow Maiden.

Vegetation. When we turn to the vegetation of Attica, the olive first calls for our attention. This tree, we learn from Herodotus (v. 82), was thought at one time to have been found in that country only; and the enthusiastic praises of Sophocles (*Œd. Col.*, 700) teach us that it was the land in which it flourished best. So great was the esteem in which it was held, that in the early legend of the struggle between the gods of sea and land, Poseidon and Athena, for the patronage of the country, the sea-god is represented as having to retire vanquished before the giver of the olive; and at a later period the evidences of this contention were found in an ancient olive tree in the Acropolis, together with three holes in the rock, said to have been made by the trident of Poseidon, and to be connected with a salt well hard by. The fig also found its favourite home in this country, for Demeter was said to have bestowed it as a gift on the Eleusinian Phytalus, *i.e.*, "the gardener." Both Cithæron and Parnes must have been wooded in former times; for on the former are laid the picturesque silvan scenes in the *Bacchæ* of Euripides, and it was from the latter that the wood came which caused the neighbouring deme of Acharnæ to be famous for its charcoal—the ἄνθρακες Παρνήσιοι of the *Acharnians* of Aristophanes (348).

Minerals. It was the thymy slopes of Hymettus, too, from which came the famous Hymettian honey. Among the other products we must notice the marble—both that of Pentelicus, which afforded a material of unrivalled purity and whiteness for building the Athenian temples, and the blue marble of Hymettus—the *trabes Hymettiæ* of Horace—which used to be transported to Rome for the construction of palaces. But the richest of all the sources of wealth in Attica was the silver mines of Laureium, the yield of which was so considerable as to render silver the principal medium of exchange in Greece, so that "a silver piece" (ἀργύριον) was the Greek equivalent term for money. Hence Æschylus speaks of the Athenians as possessing a "fountain of silver" (*Pers.*, 235), and Aristophanes makes his chorus of birds promise the audience that, if they show him favour, owls from Laureium, *i.e.*, silver pieces with the emblem of Athens, shall never fail them (*Av.*, 1106). In Strabo's time, though the mines had almost ceased to yield, silver was obtained in considerable quantities from the scoriæ; and at the present day a large amount of lead is obtained in the same way, the value of what was exported in 1869 having been £177,000 sterling.

General description. Having thus noticed the general features of the country, let us proceed to examine it somewhat more in detail. It has been already mentioned that the base line is formed by the chain of Cithæron and Parnes, running from west to east; and that from this transverse chains run southward, dividing Attica into a succession of plains. The westernmost of these, which is separated from the innermost bay of the Corinthian Gulf, called the Mare Alcyonium, by an offshoot of Cithæron, and is bounded on the east by a ridge which ends towards the Saronic Gulf in a striking two-horned peak called Kerata, is the plain of Megara. It is only for geographical purposes that we include this district under Attica, for both the Dorian race of the inhabitants, and its dangerous proximity to Athens, caused it to be at perpetual feud with that city; but its position as an outpost for the Peloponnesians, together with the fact of its having once been Ionian soil, sufficiently explains the bitter hostility of the Athenians towards the Megarians. The great importance of Megara arose from its commanding all the passes into the Peloponnese. These were three in number: one along the shores of the Corinthian Gulf, which, owing to the nature of the ground, makes a long detour; the other two starting from Megara, and passing, the one by a lofty though gradual route over the ridge of Geraneia, the other along the Saronic Gulf, under the dangerous precipices of the Scironian rocks. The town of Megara, which was built on and between two low hills rising out of the plain rather more than a mile from the sea, had the command of both gulfs by means of its two ports—that of Pegæ on the Corinthian, and that of Nicæa on the Saronic. The necessities of the case occasionally brought the Megarians and their powerful neighbours together; for the former greatly depended on Athens for their supplies, as we see from their famished state, as described by Aristophanes in the *Acharnians* (729 *seq.*), when excluded from the ports and markets of that country.

Plain of Megara.

Plain of Eleusis. To the east of the plain of Megara lies that of Eleusis, bounded on the one side by the chain of Kerata, and on the other by that of Ægaleos, through a depression in which was the line of the sacred way, where the torchlight processions from Athens used to descend to the coast, the "brightly-gleaming shores" (λαμπάδες ἀκταί) of Sophocles (*Œd. Col.*, 1049). Here a deep bay runs into the land, opposite to which, and separated from it by a strait, which forms a succession of graceful curves, was the rocky island of Salamis, at all times an important possession to the Athenians on account of its proximity to their city. The scene of the battle of Salamis was the narrowest part of this channel, where the island approaches the extremity of Ægaleos; and it was on the last declivities of that mountain that—

> "A king sate on the rocky brow
> Which looks o'er sea-born Salamis."

The eastern portion of this plain was called the Thriasian plain, and the city of Eleusis was situated in the recesses of the bay. The coast-line of this part, between the sanctuary of Poseidon at the isthmus, which was originally Ionian, and Athens, is the principal scene of the achievements of Theseus, a hero who holds the same relation to the Ionians of Greece proper as Hercules does to the Greeks at large, viz., that of being the great author of improvements in the country. In this instance his feats seem to describe the establishment of a safe means of communication. On the isthmus itself he destroys the monster Sinis, the "ravager," otherwise called Pityocamptes, or the "pine-bender," which names imply that he is the embodiment of a violent wind, though the legend grew up that he fastened his victims to the bent branches of two pines, by the rebound of which they were torn in sunder. His next exploit is near Crommyon, where he destroys a wild sow, called Phæa, or "the dusky," which probably means that he checked a torrent, since violent watercourses are often represented by that animal in Greek mythology. Then follows the struggle with the brigand Sciron, who signifies the dangerous wind, which blows with such violence in this district that at Athens the north-west wind received the name of Sciron from the neighbouring Scironian rocks; the pass, which skirts the sea at the base of the cliffs, is now known by the ill-omened title of Kake Scala, and is still regarded as a perilous transit. Finally, between Eleusis and Athens, Theseus overcomes Procrustes, or "the racker," who apparently represents the dangers of the pass between Eleusis and Athens, now called Daphne; for the ridge of Mount Ægaleos hard by was in ancient

times called Corydallus, and this, we are told by Diodorus (iv. 59), was the scene of the contest.

Plain of Athens. Next in order to the plain of Eleusis came that of Athens, which is the most extensive of all, reaching from the foot of Parnes to the sea, and bounded on the west by Ægaleos, and on the east by Hymettus. Its most conspicuous feature is the broad line of dark green along its western side, formed by the olive-groves of Colonus and the gardens of the Academus, which owe their fertility to the waters of the Cephisus, by which they are irrigated. This river is fed by copious sources on the side of Mount Parnes, and thus, unlike the other rivers of Attica, has a constant supply of water; but it does not reach the sea, nor did it apparently in classical times, having been diverted, then as now, into the neighbouring plantations; for this is what Sophocles means when he speaks of "the sleepless fountains of Cephisus, which stray forth from their channels" (*Œd. Col.*, 685 *seq.*). The position of Colonus itself is marked by two bare knolls of light-coloured earth, which caused the poet in the same chorus to apply the epithet "white" (ἀργῆτα) to that place. On the opposite side of the plain runs the other river, the Ilissus, which rises from a beautiful fountain in Mount Hymettus, and skirts the eastern extremity of the city of Athens; but this, notwithstanding its celebrity, is a mere brook, which stands in pools a great part of the year, and in summer is completely dry. The situation of Athens relatively to the surrounding objects is singularly harmonious; for, while it forms a central point, so as to be the eye of the plain, and while the altar-rock of the Acropolis and the hills by which it is surrounded are conspicuous from every point of view, there is no such exactness in its position as to give formality, since it is nearer to the sea than to Parnes, and nearer to Hymettus than to Ægaleos. The most striking summit in the neighbourhood of the city is that of Lycabettus, now Mount St George, on the north-eastern side; and the variety is still further increased by the continuation of the ridge which it forms for some distance northwards through the plain. Three roads lead to Athens from the Bœotian frontier over the intervening mountain barrier—the easternmost over Parnes, from Delium and Oropus by Deceleia, which was the usual route of the invading Lacedæmonians during the Peloponnesian War; the westernmost over Cithæron, by the pass of Dryoscephalæ, or the "Oakheads," leading from Thebes by Platæa to Eleusis, and so to Athens, which we hear of in connection with the battle of Platæa, and with the escape of the Platæans at the time of the siege of that city in the Peloponnesian War; the third, midway between the two, by the pass of Phyle, near the summit of which, on a rugged height overlooking the Athenian plain, is the fort occupied by Thrasybulus in the days of the Thirty Tyrants. On the sea-coast to the south-west of Athens rises the hill of Munychia, a mass of rocky ground, forming the acropolis of the town of Piræeus, which was once separated from the mainland; for Strabo (i. 3, § 18) speaks of it as having been formerly an island. On one side of this, towards Hymettus, lay the open roadstead of Phalerum, on the other the harbour of Piræeus, a completely land-locked inlet, safe, deep, and spacious, the approach to which was still further narrowed by moles. The eastern side of the hill was further indented by two small but commodious havens, which were respectively called Zea and Munychia.

The north-eastern boundary of the plain of Athens is formed by the graceful pyramid of Pentelicus, which received its name from the deme of Pentele at its foot, but was far more commonly known as Brilessus in ancient times. This mountain did not form a continuous chain with Hymettus, for between them intervenes a level space of ground two miles in width, which formed the entrance to the Mesogæa, an elevated undulating plain in the midst of the mountains, reaching nearly to Sunium. At the extremity of Hymettus, where it projects into the Saronic Gulf, was the promontory of Zoster, or "the Girdle," which was so called because it girdles and protects the neighbouring harbour; but in consequence of the name, a legend was attached to it, to the effect that Latona had loosed her girdle there. From this promontory to Sunium there runs a lower line of mountains, and between these and the sea a fertile strip of land intervenes, which was called the Paralia. Beyond Sunium, on the eastern coast, were two safe ports, that of Thoricus, which is defended by the island of Helene, forming a natural breakwater in front of it, and that of Prasiæ, now called Porto Raphti, or "the Tailor," from a statue at the entrance to which the natives have given that name. But it still remains to mention the most famous spot of ground in Attica, the little plain of Marathon, which lay in the north-east corner, encircled on three sides by Parnes and Pentelicus, while the fourth faces the sea and the opposite coast of Eubœa. It was on the mountain slopes that the Greeks were stationed, while the Persians with their ships occupied the coast; and on the two sides the marshes may still be traced by which the movements of the invader's host were impeded. The mound, which at once attracts the eye in the centre of the level plain, is probably the burial-place of the Athenians who fell in the battle. The bay in front is sheltered by Eubœa, and is still more protected from the north by a projecting tongue of land, called Cynosura. The mountains in the neighbourhood were the seat of one of the political parties in Attica, the Diacrii or Hyperacrii, who, being poor mountaineers, and having nothing to lose, were the principal advocates of change; while, on the other hand, the Pedieis, or inhabitants of the plains, being wealthy landholders, formed the strong conservative element, and the Parali, or occupants of the sea-coast, representing the mercantile interest, held an intermediate position between the two. Finally, there was one district of Attica, that lay without its natural boundaries, the territory of Oropus, which properly belonged to Bœotia, as it was situated to the north of Parnes; but on this the Athenians always endeavoured to retain a firm hold, because it facilitated their communications with Eubœa. The command of that island was of the utmost importance to them; for, if Ægina could rightly be called "the eyesore of the Piræeus," Eubœa was quite as truly a thorn in the side of Attica; for we learn from Demosthenes (*De Cor.*, p. 307) that at one period the pirates that made it their headquarters so infested the neighbouring sea as to prevent all navigation.

Of the condition of Attica in mediæval and modern times little need be said, for it has followed for the most part the fortunes of Athens. The population, however, has undergone a great change, independently of the large admixture of Slavonic blood that has affected the Greeks of the mainland generally, by the immigration of Albanian colonists, who now occupy a great part of the country. The most important of the classical ruins that remain outside Athens are those of the temple of Athena at Sunium, which form a conspicuous object as they surmount the headland, and gave rise to the name which it bore, until lately, of Cape Colonnæ; it is in the Doric style, of white marble, and 13 columns of the temple and a pilaster are now standing. At Eleusis the foundations of the *propylæa* of the great temple of Demeter and other buildings have been laid bare by excavation; at Thoricus there are remains of an ancient theatre; and at Rhamnus, northward from Marathon, at a little distance from the sea, are the basements and some of the columns of two temples in the same enclosure, which were dedicated to Nemesis and Themis. (H. F. T.)

ATTICUS, Titus Pomponius, the friend of Cicero, was one of the most distinguished men during the period of the decline and fall of the Roman republic. His life gives an admirable picture of the classical man of culture, who, withdrawing from the stir of political affairs, devoted himself to literary and artistic pursuits. He was born at Rome 109 B.C., and was thus three years older than Cicero, along with whom he and the younger Marius were educated. His family is said to have been of noble and ancient descent; his father belonged to the equestrian order, and was very wealthy. When Pomponius (who afterwards received the surname Atticus, on account of his long residence at Athens, and his intimate acquaintance with Greek literature) was still a young man, his father died, and he at once took the prudent resolution of transferring himself and his fortune to Athens, in order to escape the dangers of the civil war, in which he might have been involved through his connection with the murdered tribune Sulpicius Rufus. Here, in retirement, he contrived to keep himself free from the entanglements of faction, while preserving friendly relations with all parties. Sulla, who urged him to come to Rome and join his party, took no offence at his refusal, but treated him with marked kindness. He assisted the younger Marius and Brutus with money when they were fleeing from their enemies, and remained on the most cordial terms with Cæsar and Pompey, Antony and Octavianus. His most intimate friend, however, was Cicero, whose correspondence with him extended over many years, and who seems to have found his prudent counsel and sympathy a remedy for all his many troubles. His private life was tranquil and happy. He did not marry till he was 53 years of age, and his only child became the wife of Vipsanius Agrippa, the distinguished minister of Augustus. His large fortune was increased on the death of his uncle, L. Cæcilius, who bequeathed to him the greater part of his property. He formed a large library at Athens, and kept a staff of slaves engaged in making copies of valuable works. He probably derived considerable profits from the sale of these books. In 32 B.C. he was seized with an illness believed to be incurable. He resolved not to protract a painful and hopeless struggle, and died after five days of voluntary starvation. As might have been expected from his easy temper and equable disposition, Atticus professed a mild Epicureanism, but philosophical problems, as such, do not seem to have had much interest for him; he was emphatically a man of literature. Of his writings none are extant, but we have notices of two, one a Greek history of Cicero's consulship, the other, in Latin, on Roman annals, a subject to which he had given much attention. This work was highly commended for its minute exactness, chronological accuracy, and simple style.

ATTICUS HERODES, Tiberius Claudius, a very wealthy citizen of Athens, was born about 104 A.D. His grandfather's estates had been confiscated for treachery, but the fortunes of the family had been restored by the discovery in his father's house of an enormous sum of money, which the Emperor Nerva permitted them to retain. This great wealth Herodes afterwards increased by his marriage. He received a careful education under the most distinguished masters of the time, and specially devoted himself to the study of oratory, to excel in which seems to have been the ruling motive of his life. While very young he delivered a speech before one of the emperors; but it was so ill received that he was with difficulty restrained from throwing himself into the Danube. He ultimately attained to great celebrity as a speaker and as a teacher of rhetoric. Among his pupils were Marcus Aurelius and Lucius Verus. He was highly esteemed by the Antonines, particularly by Aurelius, and received many marks of favour, among others the archonship at Athens and the consulate at Rome. Atticus is principally celebrated, however, for the vast sums he expended on public purposes. He built at Athens a great race-course of marble from Pentelicus, and a splendid musical theatre, called the Odeum. At Corinth he built a theatre, at Delphi a stadium, at Thermopylæ hot baths, at Canusium in Italy an aqueduct. He even contemplated cutting a canal through the Isthmus of Corinth, but it is said did not dare to carry out his plan because the same thing had been unsuccessfully attempted before by the Emperor Nero. Many of the partially ruined cities of Greece were restored by Atticus, and numerous inscriptions testify their gratitude to their benefactor. His wealth, and, it is reported, some disagreement with regard to one of the provisions of his father's will, roused up the enmity of the Athenians against him. He withdrew from Athens, and resided at his villa near Marathon, where he died about 180 A.D. None of his writings are extant.

ATTILA, or Etzel, the famous leader of the Huns, surnamed the "Fear of the World," or the "Scourge of God," was born probably about 406 A.D. His father Mundzuk, king of the Huns, was succeeded by his brothers Octar and Rhuas; and on the death of Rhuas, in 434, Attila and his brother Bleda together ascended the throne. They ruled not only over the Huns, but over nearly all the tribes north of the Danube and the Black Sea; under their banners fought Ostrogoths, Gepidæ, Alani, Heruli, and many other Teutonic peoples. Their dominions are said to have extended from the Rhine to the frontiers of China. Attila was superstitiously reverenced by his countrymen; he was said to possess the iron sword of the war-god, Mars, and he proclaimed himself to be the man-child born at Engaddi, who was destined to rule over the whole world. In 441 and 442 the brothers ravaged Thrace and Illyria, defeated the troops of the Eastern Empire in three great battles, and penetrated as far as Thermopylæ. Peace was made on the Romans agreeing to pay a heavy tribute. About this time Attila contrived to make away with his brother Bleda, and thus secured undivided supremacy. In 445 and the following years, he again directed his attacks against the Eastern Empire, and laid waste the whole country round Constantinople. Nowhere did he meet with resistance save from the brave little town of Azimus. The empire seemed about to succumb, when Theodosius entered into negotiations and made terms with his conqueror. While matters were being arranged, a plot was laid to assassinate Attila, in which the emperor was implicated. The conspiracy was discovered, and the barbarian upbraided the Christian monarch with his want of honour and manly courage. Theodosius died soon after, and his successor, Marcian, returned a firm refusal to Attila's demands for tribute. War seemed inevitable; but at this time the attention of the Hun was drawn to the Western Empire. It is said that the Princess Honoria, sister of Valentinian, tired of her life of enforced celibacy, sent her ring and an offer of her hand to Attila, who upon this grounded his claim to a part of the empire. It is probable, however, that he merely used this as a pretext, and that his real designs were more comprehensive. He evidently thought it a favourable opportunity for taking advantage of the enmity between the Romans and the Visigoths; and to this plan he was also induced by the proposals of Genseric, king of the Vandals, who offered to unite with him against his rival, Theodoric, king of the Visigoths. In 451 Attila assembled his forces, it is said 700,000 strong, led them through the centre of Germany, probably by Franconia, and crossed the Rhine, at what place cannot be determined. He defeated the Burgundians, and pushed on through the heart of Gaul, until his centre was checked by the valiant resistance offered

by Orleans. Meanwhile, Theodoric and Aëtius, the Roman general, had collected and united their forces, and marching with all speed, arrived in time to raise the siege of Orleans. Attila retreated to a position in the plain of Chalons, and there concentrated his forces for a great engagement. A tremendous battle ensued—one of the most gigantic as well as most important contests recorded in history. The Romans, who formed one wing, were driven back, and although they kept together, and at nightfall retired to the camp of the Visigoths, Aëtius had given up the day as lost. The Visigoths, who were on the other wing, had also been repulsed, and were discouraged by the fall of their leader Theodoric. But the fortune of the day was changed by the impetuous bravery of Thorismund, Theodoric's son, who, burning to avenge his father's fall, led on the infuriated Visigoths, and drove Attila back to his camp. He even penetrated into the fortifications, but was wounded and thrown from his horse, and his followers with difficulty carried him off. Next day, Attila remained in his camp in expectation of an attack, and having thrown all his baggage into a gigantic pile in the centre of the camp to be burned in case of defeat, resolved to sell his life dearly. But no attack was made; for Thorismund was persuaded by Aëtius to march to Toulouse in order to obtain his father's kingdom. Attila was thus enabled to retire in perfect security. Next year he poured his forces through the defiles of the Alps, and laid waste the whole north of Italy. Rome itself seemed likely to fall before the invader, when his course was arrested by an embassy headed by Pope Leo. Attila at once withdrew from Italy, but the motive which led him to act thus is not known. At the time his retreat was ascribed to a miraculous interposition of Providence, Peter and Paul having appeared in the camp of the Huns along with the embassy. The whole matter is rather obscure; and scarcely more credible is the story told by Jornandes that Attila invaded Gaul a second time and was completely defeated by Thorismund. No other historian mentions this circumstance. In the year 453, Attila died from the bursting of a blood-vessel on the night of his marriage with a beautiful Gothic maiden, called Ildiko, or Hilda. He was buried by his followers with great pomp and lamentation. The vast empire over which he had ruled broke up immediately after his death, no one chief being powerful enough to seize the supremacy. In person Attila is described as having been of true Hunnish type, short, but strongly made, with a large head, flat, wide-spread nostrils, and small glittering eyes. His presence was majestic and imposing, and he excelled all his followers in military exercises.

ATTOCK, a town and fort of British India, in the Panjáb, situated on the eastern bank of the Indus, in 33° 54′ N. lat., and 72° 20′ E. long. The place is both of political and commercial importance, as the Indus is here crossed by the military and trade route through the Khaibar Pass into Afghánistán. Alexander the Great, Tamerlane, and Nádir Sháh are believed to have successively crossed the Indus at or about this spot in their respective invasions of India. The river runs past Attock in a deep rapid channel about 200 yards broad, but is easily crossed in boats or on inflated skins of oxen. A bridge of boats is maintained for a considerable part of the year, but withdrawn in the summer as soon as the melting of the snows in the northern mountains endangers it. The fort of Attock was built by the Emperor Akbar in 1581, on a low hillock beside the river. The walls are of polished stone, and the whole structure is handsome; but from a military point of view it is of little importance, being commanded by a hill, from which it is divided only by a ravine. The town was formerly a place of importance, but has now fallen into decay. On the opposite side of the river is the village of Khairábád, with a fort, also erected by Akbar according to some, or by Nádir Sháh according to others.

ATTORNEY, in *English Law*, signifies, in its widest sense, any substitute or agent appointed to act in "the turn, stead, or place of another." The term is now commonly confined to a class of qualified agents who undertake the conduct of legal proceedings for their clients. By the common law the actual presence of the parties to a suit was considered indispensable, but the privilege of appearing by attorney was conceded in certain cases by special dispensation, until the statute of Merton and subsequent enactments made it competent for both parties in all judicial proceedings to appear by attorney. Solicitors appear to have been at first distinguished from attorneys, as not having the attorney's power to bind their principals, but latterly the distinction has been between attorneys as the agents formally appointed in actions at law, and solicitors who take care of proceedings in Parliament, Chancery, Privy Council, &c. In practice, however, and in ordinary language, the terms are synonymous. Regulations regarding the qualification of attorneys are found as far back as the 20 Edward I., which required the judges to select in each county the most learned and able attorneys and apprentices to do service in the courts. By the 6 and 7 Vict. c. 73, and other statutes, the qualifications necessary for admission on the rolls of attorneys and solicitors are:—1st, The due execution of a proper contract in writing with some practising attorney or solicitor for the term of five years, or of three years if the clerk be a graduate of the universities of Oxford, Cambridge, Dublin, London, or Durham, or of the Queen's University, Ireland, or if he have been a member of the bar, a writer to the signet, a solicitor before the supreme courts in Scotland, or for ten years *bona fide* managing clerk to an attorney; 2d, The payment of the stamp duty on such contract, amounting to £80; 3d, The registry or enrolment of the contract within six calendar months; 4th, Actual service for the prescribed period in the proper business of an attorney and solicitor; but one year may be served with the London agent, and, where the service is for five years, another year with a barrister or certificated special pleader; 5th, Due notices of the application to be admitted; 6th, Fitness and capacity ascertained upon examination, and certified by the examiners; 7th, Taking the prescribed oaths, and being admitted and enrolled; 8th, The certificate of the registrar of attorneys that he is duly enrolled, and the stamped certificate of the annual payment of the duty. Attorneys duly admitted in any of the superior courts have a right to be admitted and to practise in any of the courts in the kingdom, and this right may be enforced by mandamus. They may act as advocates in certain of the inferior courts. Conveyancing, formerly considered the exclusive business of the bar, is now often performed by attorneys. Barristers are understood to require the intervention of an attorney in all cases that come before them professionally, although in criminal cases the prisoner not unfrequently engages a counsel directly by giving him a fee in open court. The relation of attorney and client disqualifies the former from dealing with his client on his own behalf, while it gives him a lien, on professional services, over the deeds, &c., of the client in his possession. An attorney may be struck off the rolls for professional or other misconduct, on application by counsel at the instance of an injured party, or, as the case generally is, of the Incorporated Law Society as representing the profession.

A letter or power of Attorney is an authority under hand and seal, empowering the person named therein to do some act on behalf of the principal, which otherwise could only be done by the principal himself. It expires with death of the

principal, and is revocable at his will, unless it has been given for a valuable consideration. *A warrant of Attorney* is an authority to one or more attorneys to appear for the party executing it, in a court of record, at the suit of the person for whose benefit it is given, and to suffer judgment summarily to pass in his favour. It is usually given as a security to creditors for the summary recovery of money lent, or sums certain, but may be used in other cases also.

ATTORNEY-GENERAL, the chief law officer appointed to manage all the legal affairs and suits in which the Crown is interested. He is appointed by patent, authorising him to hold office during the Queen's pleasure. He is *ex officio* the leader of the bar, and only counsel of the highest eminence are appointed to the office. The royal mandate of 14th December 1814 gives him precedence in all the courts, and it is now settled that in the House of Lords he has precedence of the Lord Advocate, even in Scotch appeals. He is a necessary party to all proceedings affecting the Crown, and has extensive powers of control in matters relating to charities, lunatics' estates, criminal prosecutions, &c. His assistant, also appointed by patent, is the Solicitor-General, who has full power to act in the absence of his principal, and by almost invariable usage, succeeds to his office when it becomes vacant. The income attached to these offices has hitherto been derived in great part from fees on patents for inventions, but by a recent arrangement the Attorney-General and Solicitor-General receive a salary of £7000 and £6000 respectively, exclusive of such fees as they may receive for any litigious business they may conduct on behalf of the Crown.

ATTRACTION. That the different parts of a material system influence each other's motions is a matter of daily observation. In some cases we cannot discover any material connection extending from the one body to the other. We call these cases of action at a distance, to distinguish them from those in which we can trace a continuous material bond of union between the bodies. The mutual action between two bodies is called stress. When the mutual action tends to bring the bodies nearer, or to prevent them from separating, it is called tension or attraction. When it tends to separate the bodies, or to prevent them from approaching, it is called pressure or repulsion. The names tension and pressure are used when the action is seen to take place through a medium. Attraction and repulsion are reserved for cases of action at a distance. The configuration of a material system can always be defined in terms of the mutual distances of the parts of the system. Any change of configuration must alter one or more of these distances. Hence the force which produces or resists such a change may be resolved into attractions or repulsions between those parts of the system whose distance is altered.

There has been a great deal of speculation as to the cause of such forces, one of them, namely, the pressure between bodies in contact, being supposed to be more easily conceived than any other kind of stress. Many attempts have therefore been made to resolve cases of apparent attraction and repulsion at a distance into cases of pressure. At one time the possibility of attraction at a distance was supposed to be refuted by asserting that a body cannot act where it is not, and that therefore all action between different portions of matter must be by direct contact. To this it was replied that we have no evidence that real contact ever takes place between two bodies, and that, in fact, when bodies are pressed against each other and in apparent contact, we may sometimes actually measure the distance between them, as when one piece of glass is laid on another, in which case a considerable pressure must be applied to bring the surfaces near enough to show the black spot of Newton's rings, which indicates a distance of about a ten thousandth of a millimetre. If, in order to get rid of the idea of action at a distance, we imagine a material medium through which the action is transmitted, all that we have done is to substitute for a single action at a great distance a series of actions at smaller distances between the parts of the medium, so that we cannot even thus get rid of action at a distance.

The study of the mutual action between the parts of a material system has, in modern times, been greatly simplified by the introduction of the idea of the energy of the system. The energy of the system is measured by the amount of work which it can do in overcoming external resistances. It depends on the present configuration and motion of the system, and not on the manner in which the system has acquired that configuration and motion. A complete knowledge of the manner in which the energy of the system depends on its configuration and motion, is sufficient to determine all the forces acting between the parts of the system. For instance, if the system consists of two bodies, and if the energy depends on the distance between them, then if the energy increases when the distance increases, there must be attraction between the bodies, and if the energy diminishes when the distance increases, there must be repulsion between them. In the case of two gravitating masses m and m' at a distance r, the part of the energy which depends on r is $-\frac{mm'}{r}$. We may therefore express the fact that there is attraction between the two bodies by saying that the energy of the system consisting of the two bodies increases when their distance increases. The question, therefore, Why do the two bodies attract each other? may be expressed in a different form. Why does the energy of the system increase when the distance increases?

But we must bear in mind that the scientific or science-producing value of the efforts made to answer these old standing questions is not to be measured by the prospect they afford us of ultimately obtaining a solution, but by their effect in stimulating men to a thorough investigation of nature. To propose a scientific question presupposes scientific knowledge, and the questions which exercise men's minds in the present state of science may very likely be such that a little more knowledge would show us that no answer is possible. The scientific value of the question, How do bodies act on one another at a distance? is to be found in the stimulus it has given to investigations into the properties of the intervening medium.

Newton, in his *Principia*, deduces from the observed motions of the heavenly bodies the fact that they attract one another according to a definite law. This he gives as a result of strict dynamical reasoning, and by it he shows how not only the more conspicuous phenomena, but all the apparent irregularities of the celestial motions are the calculable results of a single principle. In his *Principia* he confines himself to the demonstration and development of this great step in the science of the mutual action of bodies. He says nothing there about the means by which bodies gravitate towards each other. But his mind did not rest at this point. We know that he did not believe in the direct action of bodies at a distance.

> "It is inconceivable that inanimate brute matter should, without the mediation of something else which is not material, operate upon and affect other matter without mutual contact, as it must do if gravitation in the sense of Epicurus be essential and inherent in it. . . . That gravity should be innate, inherent, and essential to matter, so that one body can act upon another at a distance, through a vacuum, without the mediation of anything else, by and through which their action and force may be conveyed from one to another, is to me so great an absurdity, that I believe no man, who has in philosophical matters a competent faculty of thinking, can ever fall into it."—*Letter to Bentley.*

And we also know that he sought for the mechanism of

gravitation in the properties of an æthereal medium diffused over the universe.

"It appears, from his letters to Boyle, that this was his opinion early, and if he did not publish it sooner it proceeded from hence only, that he found he was not able, from experiment and observation, to give a satisfactory account of this medium and the manner of its operation in producing the chief phenomena of nature."[1]

In his *Optical Queries*, indeed, he shows that if the pressure of this medium is less in the neighbourhood of dense bodies than at great distances from them, dense bodies will be drawn towards each other, and that if the diminution of pressure is inversely as the distance from the dense body the law will be that of gravitation. The next step, as he points out, is to account for this inequality of pressure in the medium; and as he was not able to do this, he left the explanation of the cause of gravity as a problem to succeeding ages. As regards gravitation the progress made towards the solution of the problem since the time of Newton has been almost imperceptible. Faraday showed that the transmission of electric and magnetic forces is accompanied by phenomena occurring in every part of the intervening medium. He traced the lines of force through the medium; and he ascribed to them a tendency to shorten themselves and to separate from their neighbours, thus introducing the idea of stress in the medium in a different form from that suggested by Newton; for, whereas Newton's stress was a hydrostatic pressure in every direction, Faraday's is a tension along the lines of force, combined with a pressure in all normal directions. By showing that the plane of polarisation of a ray of light passing through a transparent medium in the direction of the magnetic force is made to rotate, Faraday not only demonstrated the action of magnetism on light, but by using light to reveal the state of magnetisation of the medium, he "illuminated," to use his own phrase, "the lines of magnetic force."

From this phenomenon Thomson afterwards proved, by strict dynamical reasoning, that the transmission of magnetic force is associated with a rotatory motion of the small parts of the medium. He showed, at the same time, how the centrifugal force due to this motion would account for magnetic attraction.

A theory of this kind is worked out in greater detail in Clerk Maxwell's *Treatise on Electricity and Magnetism*. It is there shown that, if we assume that the medium is in a state of stress, consisting of tension along the lines of force and pressure in all directions at right angles to the lines of force, the tension and the pressure being equal in numerical value and proportional to the square of the intensity of the field at the given point, the observed electrostatic and electromagnetic forces will be completely accounted for.

The next step is to account for this state of stress in the medium. In the case of electromagnetic force we avail ourselves of Thomson's deduction from Faraday's discovery stated above. We assume that the small parts of the medium are rotating about axes parallel to the lines of force. The centrifugal force due to this rotation produces the excess of pressure perpendicular to the lines of force. The explanation of electrostatic stress is less satisfactory, but there can be no doubt that a path is now open by which we may trace to the action of a medium all forces which, like the electric and magnetic forces, vary inversely as the square of the distance, and are attractive between bodies of different names, and repulsive between bodies of the same names.

The force of gravitation is also inversely as the square of the distance, but it differs from the electric and magnetic forces in this respect, that the bodies between which it acts cannot be divided into two opposite kinds, one positive and the other negative, but are in respect of gravitation all of the same kind, and that the force between them is in every case attractive. To account for such a force by means of stress in an intervening medium, on the plan adopted for electric and magnetic forces, we must assume a stress of an opposite kind from that already mentioned. We must suppose that there is a pressure in the direction of the lines of force, combined with a tension in all directions at right angles to the lines of force. Such a state of stress would, no doubt, account for the observed effects of gravitation. We have not, however, been able hitherto to imagine any physical cause for such a state of stress. It is easy to calculate the amount of this stress which would be required to account for the actual effects of gravity at the surface of the earth. It would require a pressure of 37,000 tons' weight on the square inch in a vertical direction, combined with a tension of the same numerical value in all horizontal directions. The state of stress, therefore, which we must suppose to exist in the invisible medium, is 3000 times greater than that which the strongest steel could support.

Another theory of the mechanism of gravitation, that of Le Sage, who attributes it to the impact of "ultramundane corpuscules," has been already discussed in the article ATOM, *supra*, p. 46.

Sir William Thomson[2] has shown that if we suppose all space filled with a uniform incompressible fluid, and if we further suppose either that material bodies are always generating and emitting this fluid at a constant rate, the fluid flowing off to infinity, or that material bodies are always absorbing and annihilating the fluid, the deficiency flowing in from infinite space, then, in either of these cases, there would be an attraction between any two bodies inversely as the square of the distance. If, however, one of the bodies were a generator of the fluid and the other an absorber of it, the bodies would repel each other.

Here, then, we have a hydrodynamical illustration of action at a distance, which is so far promising that it shows how bodies of the same kind may attract each other. But the conception of a fluid constantly flowing out of a body without any supply from without, or flowing into it without any way of escape, is so contradictory to all our experience, that an hypothesis, of which it is an essential part, cannot be called an *explanation* of the phenomenon of gravitation.

Dr Robert Hooke, a man of singular inventive power, in 1671 endeavoured to trace the cause of gravitation to waves propagated in a medium. He found that bodies floating on water agitated by waves were drawn towards the centre of agitation.[3] He does not appear, however, to have followed up this observation in such a way as to determine completely the action of waves on an immersed body.

Professor Challis has investigated the mathematical theory of the effect of waves of condensation and rarefaction in an elastic fluid on bodies immersed in the fluid. He found the difficulties of the investigation to be so great that he has not been able to arrive at numerical results. He concludes, however, that the effect of such waves would be to attract the body towards the centre of agitation, or to repel it from that centre, according as the wave's length is very large or very small compared with the dimensions of the body. Practical illustrations of the effect of such waves have been given by Guyot, Schellbach, Guthrie, and Thomson.[4]

A tuning-fork is set in vibration, and brought near a delicately suspended light body. The body is immediately

[1] Maclaurin's account of Sir Isaac Newton's discoveries.

[2] *Proceedings of the Royal Society of Edinburgh*, 7th Feb. 1870.

[3] *Posthumous Works*, edited by R. Waller, pp. xiv. and 184.

[4] *Philosophical Magazine*, June 1871.

attracted towards the tuning-fork. If the tuning-fork is itself suspended, it is seen to be attracted towards any body placed near it.

Sir W. Thomson has shown that this action can in all cases be explained by the general principle that in fluid motion the average pressure is least where the average energy of motion is greatest. Now, the wave motion is greatest nearest the tuning-fork, the pressure is therefore least there; and the suspended body being pressed unequally on opposite sides, moves from the side of greater pressure to the side of less pressure, that is towards the tuning-fork. He has also succeeded in producing repulsion in the case of a small body lighter than the surrounding medium.

It is remarkable that of the three hypotheses, which go some way towards a physical explanation of gravitation, every one involves a constant expenditure of work. Le Sage's hypothesis of ultramundane corpuscules does so, as we have shown in the article Atom. That of the generation or absorption of fluid requires, not only constant expenditure of work in emitting fluid under pressure, but actual creation and destruction of matter. That of waves requires some agent in a remote part of the universe capable of generating the waves.

According to such hypotheses we must regard the processes of nature not as illustrations of the great principle of the conservation of energy, but as instances in which, by a nice adjustment of powerful agencies not subject to this principle, an apparent conservation of energy is maintained. Hence, we are forced to conclude that the explanation of the cause of gravitation is not to be found in any of these hypotheses.

For the mathematical theory of attraction and attraction of ellipsoids, see Potential; for attraction of gravitation, capillary attraction, and attraction of cohesion, see respectively Gravitation, Capillary Attraction, and Constitution of Bodies. (J. C. M.)

ATTWOOD, Thomas, musical composer, was born in London in 1767. As one of the boy choristers in the chapel royal he received his early instruction in music from Nares and Ayrton. In 1783 he was sent to study abroad at the expense of the prince of Wales, who had been favourably impressed by his skill as a performer on the harpsichord. After spending two years at Naples, Attwood proceeded to Vienna, where he became a favourite pupil of Mozart. On his return to London he held for a short time an appointment as one of the chamber musicians to the prince of Wales. In 1795 he was chosen organist of St Paul's, and in the following year he succeeded Dr Dupuis as composer to the chapels royal. His court connection was further confirmed by his appointment as musical instructor to the duchess of York and afterwards to the princess of Wales. For the coronation of George IV. he composed the anthem, *The King shall Rejoice*, a work of high merit. The king, who had neglected him for some years on account of his connection with the princess of Wales, now restored him to favour, and in 1821 appointed him organist to his private chapel at Brighton. Soon after the institution of the Royal Academy of Music, Attwood was chosen one of the professors. He wrote the anthem, *O Lord, grant the King a Long Life*, which was performed at the coronation of William IV., and he was composing a similar work for the coronation of Queen Victoria when he died (March 24, 1838). Attwood's compositions are favourable specimens of the English school. His services and anthems were published in a collected form after his death by his pupil Walmesley, and are frequently used in cathedral worship. Of his secular compositions several songs and glees are well known and popular. The operas which he composed in early life are now almost forgotten, belonging, as they do, to a period when English music was at its lowest ebb.

ATWOOD, George, an author celebrated for the accuracy of his mathematical and mechanical investigations, and considered particularly happy in the clearness of his explanations, and the elegance of his experimental illustrations, was born in the early part of the year 1746. He was educated at Westminster school, to which he was admitted in 1759. Six years afterwards he was elected *off* to Trinity College, Cambridge. He took his degree of Bachelor of Arts in 1769, with the rank of third wrangler and first Smith's prizeman. These distinctions were amply sufficient to give him a claim to further advancement in his own college. In due time he obtained a fellowship, and was afterwards one of the tutors of the college. He became Master of Arts in 1772, and in 1776 was elected a fellow of the Royal Society of London. In the year 1784 he ceased to reside at Cambridge, and soon afterwards received from Mr Pitt a patent office, which required but little of his attendance, and enabled him still to devote a considerable portion of his time to his special studies. He died in 1807. Atwood's published works, exclusive of papers contributed to the *Philosophical Transactions*, for one of which he obtained the Copley medal, are as follows:—(1.) *Analysis of a Course of Lectures on the Principles of Natural Philosophy*, Cambridge, 1784. (2.) *Treatise on the Rectilinear Motion and Rotation of Bodies*, Cambridge, 1784, which contains a good account of the elementary principles of mechanics, though it is deficient in the application of higher mathematical analysis. It also gives some interesting experiments, by means of which mechanical truths can be ocularly exhibited and demonstrated, and describes the machine, since called by Atwood's name, for verifying experimentally the laws of simple acceleration of motion. (3.) *Review of the Statutes and Ordinances of Assize which have been established in England from the 4th year of King John*, 1202, *to the 37th of his present Majesty*, London, 1801, a work of some historical research. (4.) *Dissertation on the Construction and Properties of Arches*, London, 1801, with supplement, pt. i. 1801, pt. ii. 1804, an elaborate and, in its time, valuable work, though it is now completely superseded.

ATYS, Attis, or Attes, in the *Phrygian and Lydian Mythology*, a youth beloved for his beauty by the goddess Rhea, there called Agdistis. Like Adonis, he was a personification of the changes in nature, from the beauty of spring and summer to the severity and darkness of winter. The story, as told at Pessinus, the centre of the worship of the goddess, was that she had born to Zeus a being both male and female; that the gods, displeased, had transformed this being into a tree, from the fruit of which the daughter of the river-god Sangarius bore a boy, who grew up among herdsmen marvellous in his beauty, so as to win the love of Agdistis. This was Atys, and he was about to be married to the king's daughter of Pessinus, when the goddess appeared among the guests, terrified them, and caused Atys to run to the woods, where he maimed himself and was transformed into a pine tree; from his blood sprang violets. Agdistis begged Zeus to restore him, but he could only assure her that the youth would never decay, and that his hair would always grow. She conveyed the pine to her cave at Pessinus, and gave herself up to grief.

AUBAGNE, a town of France, in the department of Bouches-du-Rhône, with a population of 7408, who carry on the manufacture of wine, pottery, leather, coarse cloth, &c. The only remarkable monument is a fountain to the memory of the Abbé Barthélemy, whose family was long connected with the town.

AUBE, a department of France, bounded on the N. by the department of Marne, N.W. by Seine-et-Marne, W.

by Yonne, S. by Cote-d'Or, and E. by Haute-Marne. It consists of a portion of Champagne and Vallage, with a small part of Burgundy, and has an area of 2317 square miles. Its general inclination from S.E. to N.W. presents little variety of surface, the only elevations being a double line of hills along the course of the Seine, never exceeding 1150 feet in height. The department belongs to the Seine basin, and is watered by that river and its tributaries, the Ource, the Sarce, the Melda, and the Aube, &c. The climate is comparatively mild, but damp. Heavy rains fall at the beginning of winter. In the N. and N.W. the soil is dry and sterile; but the S. and E. districts are very fertile, particularly the valleys, which are admirably adapted for the cultivation of the vine. About two-thirds of the surface consists of arable land, and the agricultural condition of the country is improving. The principal productions are wheat, rye, oats, potatoes, and wine, of which last about one-half is exported. In minerals Aube is one of the poorest departments in France; a few iron mines have been worked, but with insignificant results. Chalk and clay are abundant; and there are also quarries of marble, lithographic stone, and building stone. The principal manufacture is hosiery; but the department also produces glass, earthenware, paper, sugar, and ropes, and has a large number of distilleries, tile-works, and dye-works, and an oil factory. Among the celebrated men connected with Aube are Villehardouin, Pope Urban IV., Mignard, Danton, Beugnot, and Ulbach. The capital is Troyes, and the arrondissements are Troyes, Arcis-sur-Aube, Nogent-sur-Seine, Bar-sur-Aube, and Bar-sur-Seine. Population in 1872, 255,687.

AUBENAS, a town of France, department of Ardèche, near the river of that name, 14 miles S.W. of Privas. It is beautifully situated on the slope of a hill, but its streets generally are crooked and narrow. It is surrounded by a ruinous wall flanked with towers, and has an old Gothic castle, now occupied by the municipal authorities. As the centre of the silk trade of the surrounding district, it is a place of considerable traffic, and there is besides a large local manufacture of silk and woollen goods. Population, 7694.

AUBER, Daniel François Esprit, musical composer, the chief representative of the French school, was the son of a Paris printseller. He was born at Caen, in Normandy, on the 29th January 1782, while his mother was on a visit to that town. Destined by his father to the pursuits of trade, he was allowed, nevertheless, to indulge his fondness for music, and learnt to play at an early age on several instruments, his first teacher being the Tyrolean composer, Ladurner. Sent at the age of twenty to London to complete his business training, he returned after the rupture of the peace of Amiens. He had already attempted musical composition, and at this period produced several *concertos pour basse*, in the manner of the violoncellist, Lamare, in whose name they were published. The praise given to his concerto for the violin, which was played at the Conservatoire by Mazas, encouraged him to undertake the resetting of the old comic opera, *Julie*. Conscious by this time of the need of regular study of his chosen art, he placed himself under the severe training of Cherubini, by which the special qualities of the young composer were admirably developed. In 1813 he made his *début* in an opera in one act, the *Séjour Militaire*, the unfavourable reception of which put an end for some years to his attempts as composer. But the failure in business and death of his father, in 1819, compelled him once more to turn to music, and to make that which had been his pastime the serious employment of his life. He produced another opera, the *Testament et les Billets-doux*, which was no better received than the former. But he persevered, and the next year was rewarded by the complete success of his *Bergère Châtelaine*, an opera in three acts. This was the first in a long series of brilliant successes, terminating only in the eighty-sixth year of his age. In 1822 began his long association with M. Scribe, who shared with him, as librettist, the success and growing popularity of his compositions. The opera of *Leicester*, in which they first worked together (1823), is remarkable also as showing the first evidences of the influence of Rossini on Auber's style. This style was, however, distinctly original, and was easily recognisable. A phrase of Auber, said his friend Théodore Gautier, is not the phrase of any one else. His characteristics are lightness and facility, sparkling vivacity, grace and elegance, clear and piquant melodiousness,—these marking him out as a true son of France, and making him her darling singer. Depth of thought, elevation of sentiment, intensity of passion, inspiration which grasps the sublime and the infinite—these are not in Auber.

Devoted by preference to the comic opera, as the most fitting field for his talents, he ventured on more than one occasion to pass into the field of grand opera, and in his *La Muette de Portici*, familiarly known as *Masaniello*, he achieved his greatest musical triumph. Produced at Paris in 1828, it rapidly became a European favourite, and its overture, songs, and choruses were everywhere heard. The duet, *Amour sacré de la patrie*, was welcomed like a new *Marseillaise;* sung by Nourrit at Brussels in 1830, it became the signal for the revolution which broke out there. Among his other works, about fifty in all, the more important are—*Fra Diavolo* (1830), *Lestocq* (1834), *L'Ambassadrice* (1836), *Le Domino Noir* (1837), *Le Lac des Fées* (1839), *Les Diamants de la Couronne* (1841), *Haydée* (1847), *Marco Spada* (1853), and *La Fiancée du roi de Garbe* (1864). Official and other dignities testified the public appreciation of Auber's works. In 1829 he was elected member of the Institute, in 1830 he was named director of the court concerts, and in 1842 he succeeded Cherubini as director of the Conservatoire. He was also a member of the Legion of Honour from 1825, and attained the rank of commander in 1847. One of Auber's latest compositions was a march, written for the opening of the International Exhibition in London in 1862. His fascinating manners, his witty sayings, and his ever ready kindness and beneficence won for him a secure place in the respect and love of his fellow-citizens. He remained in his old home during the German siege of Paris, 1870–71, but the miseries of the Communist war which followed sickened his heart, and he at last refused to touch his beloved instrument, or to take food. He died May 13, 1871. (W.L.R.C.)

AUBIN, a town of France, in the department of Aveyron and arrondissement of Villefranche, principally remarkable for its extensive mines of coal, sulphur, and alum. It also carries on an active trade in sheep, iron goods, &c. A church of the 12th century, with some remarkable sculpture, and the ruins of the castle of the counts of Rouergue, are still in existence. Population, 8863.

The name Aubin, or St Aubin, is one of the most frequent in France, being borne by upwards of fifty villages from the Pyrenees to Jersey.

AUBURN, the capital of Cayuga county, in the state of New York, on the railway between Albany and Buffalo, 174 miles W. of the former. The irregularity of the surface on which the city is built has prevented the complete carrying out of the rectangular arrangement of streets, which is so much in favour in the United States, but the thoroughfares are wide and lined with trees, and the houses for the most part well built. The principal public buildings are in Genesee Street. The most remarkable of the institutions is the state prison, founded in 1816, which is conducted on the "silent system," and usually contains upwards of 1000 prisoners, who are employed each in

the work to which he has been trained. Auburn also possesses a Presbyterian theological seminary, founded in 1821, an academy, five public free schools, sixteen churches, an orphan asylum, two opera houses, and several newspaper offices. The water-power supplied by the outlet of the neighbouring lake of Owasco is utilised in a number of manufactories. Cotton and woollen goods, carpets, agricultural implements and other tools, paper, flour, and beer are the principal products.

AUBUSSON, a town of France, situated in a picturesque valley on the banks of the Creuse, in the department to which that river gives its name. It is said to have owed its origin to a number of Saracens, who, having escaped from the battle in which their nation was defeated by Charles Martel, were enticed by the beauty and convenience of the spot to establish themselves permanently there. It has long been famous for its carpets and tapestry, the art of weaving which was probably derived from those Eastern settlers, and it also manufactures common cotton and woollen goods, leather, tobacco, &c. Population, 6625.

AUCH, the ancient *Climberrum* or *Augusta Auscorum*, one of the most ancient cities of France, capital of the department of Gers. In Cæsar's time this was the chief town of the Ausci. In the 8th century it became the capital of Gascony; and when that district was divided into countships, was the capital of Armagnac. The site of the modern town does not exactly coincide with that of the ancient, being on the opposite (the left) bank of the river Gers. Auch was probably destroyed by the Saracens about 724 A.D., and was afterwards rebuilt in its present picturesque situation on the slope of a hill. On the opposite side of the river, and occupying the site of the ancient city, is a considerable suburb, which is connected with the town by a bridge; and communication between the lower and the upper town is afforded by long flights of steps. The streets, though narrow, are generally well built, and a fine promenade in the upper part of the town gives a magnificent view of the surrounding country. Auch is the seat of an archbishopric, which was founded in the 4th century, and gave, till the Revolution, the title of Primate of Aquitania to the holder of the see. It has tribunals of commerce and primary jurisdiction, a royal college, an agricultural society, a theological seminary, with a museum and an extensive library, a theatre, &c. The cathedral of St Mary, one of the most magnificent in France, was commenced in the reign of Charles VIII. (1489), and finished in that of Louis XV. It exhibits several styles of architecture, contains many elegant monuments, and is adorned with fine stained-glass windows and carved woodwork. The *préfecture*, formerly the archiepiscopal palace, is a vast and noble edifice. The principal manufactures are hats, various kinds of linen and cotton stuffs, leather, &c., and there is a considerable trade, especially in the brandies of Armagnac. Population in 1872, 13,087.

AUCHTERARDER, a town and parish of Scotland, county of Perth, 15 miles W.S.W. of Perth. The town consists of a single street about a mile in length. It was formerly a royal burgh, but is now disfranchised. Near it is an ancient castle, said to have been a hunting-seat of Malcolm Canmore. It was in connection with this parish that the ecclesiastical dispute arose which led to the Disruption in the Church of Scotland in 1843. Population of town in 1871, 2599.

AUCHTERMUCHTY, a royal burgh and parish of Scotland, county of Fife, 8 miles W.S.W. of Cupar. The town is irregularly built on an elevated site, and is divided by the Leverspool, a rapid streamlet which runs down its centre. The manufacture of linen is carried on. Population of burgh in 1871, 1082.

AUCKLAND, a province of New Zealand, consisting of the northern portion of North Island, and bounded for the most part on the S. by the 39th parallel of latitude. In the N.W. it runs out into a peninsula between 200 and 300 miles in length, with a very irregular coast-line, especially on the eastern side. The total area of the province is about 17,000,000 acres, of which nearly 11,275,000 are still in possession of the Maoris, who are, however, continually disposing of their claims to the Government. The surface of the province is of a very varied character, presenting wide and fertile plains, stretches of fern-heath and swamp, mountain ranges and isolated peaks, tracts of richly-wooded jungle, rocky plateaus, and districts of strange volcanic activity. All round the coast there are a large number of natural harbours, and the most of the interior is traversed by navigable streams. The principal river-system is that of the Waikato (or Rushing Water), which rises in the Taupo Lake, in the south of the province, forces its way through an extensive rocky table-land, flows onwards for about 35 miles through a rich but marshy basin, joins its waters with the Waipa (or Peaceful Water), its largest tributary, cuts a passage through the Taupiri range, and after traversing the fertile expanse of its lower basin, turns abruptly to the W. and falls into the sea about 35 miles S. of the city of Auckland. The value of the Waikato as a commercial highway is greatly lessened by its mouth being encumbered with sandbanks, that prevent the entrance of ships. To the E. of this river lies the valley of the Thames, fertile and well watered by several streams, and still further eastward extends the versant of the Bay of Plenty. The course of settlement has hitherto advanced for the most part along the valleys of the Waikato and the Thames,—Cambridge, about 104 miles S. of the city of Auckland, being the frontier station in the former, and Tapapa, a little further to the S. in the latter. Nearly the whole of the N.W. peninsula is occupied by a scattered population, and various flourishing townships are situated along the coast on all sides. In 1873 there were 3842 holdings in the province, and about 225,000 acres had been broken up. Hitherto the cultivation of the cereals has not proved sufficiently remunerative, though climate and soil are equally favourable, and the attention of the farmer has principally been turned to the rearing of the various descriptions of live stock, more especially sheep. The natural wealth of the province consists principally in its gold and timber. Coal has been found in several districts, and a few mines have been successfully worked, as Kawakawa (at the Bay of Islands), Drury, and Whangarei; but the most important deposits are comparatively undisturbed. It is believed that iron may eventually be found in considerable quantities, and various minerals have been pointed out in the interior by scientific travellers. The chief seats of the gold-diggings are the Coromandel peninsula and the Thames valley. The quantity exported in 1871 was valued at £1,888,708. The most important timber tree is the kauri-pine, which is peculiar to Auckland, and does not grow further south than 37° 30′. It is of magnificent dimensions, and valuable, not only as the most extensively used building material, but on account of the fossil gum which is found wherever the kauri forest has been. This gum forms one of the chief articles of export, about 14,277 tons being the amount in the three years 1870, 1871, and 1872. There are various other trees of considerable value, such as the rimu, the kahikatea, and the totara. The timber trade, both domestic and foreign, is increasing in importance, and shipbuilding is extensively carried on. There are large districts overgrown with the *Phormium* or New Zealand flax, and the right to cut it on the waste lands is granted by the Government at a low price. In 1873, 1497 tons

of the prepared fibre, valued at £27,783, were exported, besides a considerable quantity of manufactured rope. These great necessities of commerce, roads and railways, are being constructed in various directions. A line is in course of formation from Auckland up the valley of the Waikato, as far as Newcastle, at the confluence of the Waipa, and a survey has been made for about 20 miles further. A road runs from Bowen, on the Bay of Plenty, across the country, through the wonderful lake district, with its boiling fountains, steam geysers, and mud-baths, round by the east coast of Taupo Lake, and over the highlands to Napier, in Hawke's Bay province. The history of Auckland was for long the history of New Zealand, and will be fully treated under that heading. (See NEW ZEALAND.)

For a descriptive account of a large part of the province, the reader is referred to Dr Hochstetter's valuable works, especially to his *New Zealand*, 1863. A very graphic sketch of some of the natural curiosities is furnished by Anthony Trollope in his *Australia and New Zealand*, vol. ii.

AUCKLAND, the capital of the above province, is finely situated on an isthmus in the N.W. peninsula, on the S. shore of the Waitemata harbour, which is formed by an inlet of the Hauraki Gulf. Lat. 36° 51′ S., long. 174° 50′. On the other side of the isthmus lies the harbour and town of Manukau, which serves as a supplementary port to the city. Auckland was founded in 1840 by Governor Hobson, and became a burgh in 1851. It was till 1865 the seat of the Government, which is now situated at Wellington. The city has a fine appearance, especially from the harbour, and is surrounded by a number of flourishing suburban villages, with several of which it is connected by railway. Among the public buildings in the city and neighbourhood may be mentioned the governor's house, the cathedral, St John's Episcopal college, about 4 miles distant, the Auckland college and grammar school, the Episcopal grammar school, in the suburb of Parnell, the provincial hospital, the provincial lunatic asylum, and the orphanage at Parnell. A wharf, 1690 feet in length, has been built opposite the centre of the city, and affords excellent accommodation for the gradually increasing traffic of the harbour. In 1872, 170 non-colonial vessels, with a tonnage of 51,257 tons, entered the port, besides a large number of coasting ships. There are registered at Auckland 167 sailing vessels and 20 steamships, most of them of provincial build. The population, which was 7989 in 1862, had increased by 1871 to 12,937 (with the suburbs to 18,000), and is now estimated at about 21,000.

AUCKLAND ISLANDS, a group discovered in 1806 by Captain Briscoe, of the English whaler "Ocean," about 180 miles S. of New Zealand, in lat. 50° 24′, long. 166° 7′ E. The islands, of volcanic origin, are very fertile, and are covered with forest. They were granted to the Messrs Enderby by the British Government as a whaling station, but the establishment was abandoned in 1852. (See Raynal's *Auckland Islands*, 1874.)

AUCKLAND, WILLIAM EDEN, BARON, an eminent diplomatist and politician, third son of Sir Robert Eden, Bart., of West Auckland, was born in 1744. He was educated at Eton and Oxford, and adopted the profession of the law. At the age of twenty-seven he resigned his practice at the bar, and engaged in political life as under-secretary to Lord Suffolk. By the favour of the duke of Marlborough, he obtained a seat for Woodstock, and soon gave proof of his ability in the House. He attached himself to Lord North's party, and after serving under Lord Carlisle on the unsuccessful commission to the colonists in America, acted as secretary to that nobleman, when he held the post of viceroy in Ireland. During this time he had obtained the offices of director and auditor of Greenwich Hospital, which probably yielded him an income sufficient for carrying on his political career. In 1783 he took a leading part in negotiating the remarkable coalition between North and Fox, and was rewarded by being made vice-treasurer of Ireland. In 1784 he opposed Pitt's proposal for commercial reciprocity with Ireland, but in so doing contrived to separate himself to some extent from his own party, and shortly after accepted from Pitt the office of plenipotentiary at Paris. Here he successfully negotiated the important commercial treaty with France; and after his appointment as ambassador to Spain, he rendered valuable service in settling the dispute between the British and French Governments with regard to the affairs of Holland. In 1789 he was made an Irish peer, with the title of Baron Auckland, and in 1793 he was raised to the British peerage as Baron Auckland, of West Auckland, Durham. For three years, 1798-1801, he held office as postmaster-general. He died suddenly in 1814. In 1776 he married the sister of the first earl of Minto, by whom he had a large family. Besides numerous pamphlets on political matters of the day, Lord Auckland wrote a treatise on the *Principles of the Penal Law*, 1771. His political conduct has been frequently censured; he was a skilful diplomatist, and as a statesman was specially remarkable for his clear grasp of economic principles. His *Journal and Correspondence*, 4 vols. 1860-1862, published by his son, the bishop of Bath and Wells, throws considerable light on the political history of his time.

AUCKLAND, GEORGE EDEN, EARL OF, Governor-General of India, born 20th August 1784, was the second son of the subject of the preceding notice. He completed his education at Oxford, and was admitted to the bar in 1809. His elder brother was drowned in the Thames in the following year; and in 1814, on the death of his father, he took his seat in the House of Lords as Baron Auckland. He supported the Reform party steadily by his vote, and in 1830 was made president of the Board of Trade and master of the Mint. In 1834 he held office for a few months as first lord of the Admiralty, and in 1835 he was appointed Governor-General of India. He proved himself to be a painstaking and laborious legislator, and devoted himself specially to the improvement of native schools, and the expansion of the commercial industry of the nation committed to his care. These useful labours were interrupted in 1838 by the hostile movements of the Persians, which excited the fears not only of the Anglo-Indian Government but of the home authorities. Lord Auckland resolved to enter upon a war in Afghanistan, and on the 1st October 1838, published at Simla his famous manifesto. The early operations were crowned with success, and the Governor-General received the title of Earl of Auckland. But reverses followed quickly, and in the ensuing campaigns the British troops suffered the most severe disasters. Lord Auckland had the double mortification of seeing his policy a complete failure, and of being superseded before his errors could be rectified. In the autumn of 1841 he was succeeded in office by Lord Ellenborough, and returned to England in the following year. In 1846 he was made first lord of the Admiralty, which office he held until his death, 1st January 1849. He died unmarried, and the earldom became extinct.

AUCTION, a mode of selling property by offering it to the highest bidder in a public competition. By 8 Vict. c. 15, the uniform duty of £10 per annum is imposed on every licence to carry on the business of auctioneer, but duties on sales by auction are abolished. It is the duty of an auctioneer to sell for the best price he can obtain, and his authority cannot be delegated to another unless by special permission of his employer. The auctioneer's name must be exhibited on some conspicuous place during the

sale, under a penalty of £20. Sales by auction usually take place under certain conditions, which it is the duty of the auctioneer to read to the bidders before the sale begins. To complete a sale by auction there must be a *bidding* by, or on behalf of, a person capable of making a contract, and an *acceptance* thereof by the auctioneer, and until the bidding is accepted both vendor and bidder are free, and may retract if they choose. If due notice is given, an agent may be employed to bid on behalf of the seller, but the employment of several bidders is improper, and if the sale is declared to be *without reserve*, any bidding on the behalf of the seller will vitiate the sale. *Puffing*, it has been said, is illegal, even if there be only one puffer. On the other hand, any hindrance to a free sale, either by a bidder deterring competitors from offering against him, or by an engagement among the competitors to refrain from bidding, in order to keep down the price of the goods and then share the profit, is a fraud upon the vendor. Two persons, however, may agree not to bid against each other. Auctioneers are entitled by their licence to act as appraisers also.

AUDÆUS, or AUDIUS, a reformer of the 4th century, by birth a Mesopotamian. He suffered much persecution from the Syrian clergy for his fearless censure of their irregular lives, and was expelled from the church. He was afterwards banished into Scythia, where he gained many followers and established the monastic system. He died there at an advanced age, about 370 A.D. The Audæans celebrated the feast of Easter on the same day as the Jewish Passover, and they were also charged with attributing to the Deity a human shape. They appear to have founded this opinion on Genesis i. 26.

AUDE, a southern department of France, forming part of the old province of Languedoc, bounded on the E. by the Mediterranean, N. by the departments of Hérault and Tarn, N.W. by Upper Garonne, W. by Ariége, and S. by that of Eastern Pyrenees. It lies between lat. 42° 40′ and 34° 30′ N., and is 80 miles in length from E. to W., and 60 miles in breadth from N. to S. Area, 2341 square miles. The department of Aude is traversed on its western boundary from S. to N. by a mountain range of medium height, which unites the Pyrenees with the Southern Cevennes; and its northern frontier is occupied by the Black Mountains, the most western part of the Cevennes chain. The Corbières, a branch of the Pyrenees, runs in a S.W. and N.E. direction along the southern district. The Aude, its principal river, has almost its entire course in the department. Its principal affluents on the left are the Fresquel, Orbiel, Argent-Double, and Cesse; on the right, the Guette, Salse, and Orbieu. The canal of Languedoc, which unites the Atlantic with the Mediterranean, traverses the department from E. to W. The lowness of the coast causes a series of large lagunes, the chief of which are those of Bages, Sigean, Narbonne, Palme, and Leucate. The climate is variable, and often sudden in its alterations. The wind from the N.W., known as the *Cers*, blows with great violence, and the sea breeze is often laden with pestilential effluvia from the lagunes. Various kinds of wild animals, as the chamois, bear, wild boar, wolf, fox, and badger, inhabit the mountains and forests; game of all kinds is plentiful; and the coast and lagunes abound in fish. Mines of iron, copper, lead, manganese, cobalt, and antimony exist in the department; and, besides the beautiful marbles of Cascastel and Caunes, there are quarries of lithographic stone, gypsum, limestone, and slate. The coal mines are for the most part abandoned. The mountains contain many mineral springs, both cold and thermal. The agriculture of the department is in a very flourishing condition. The meadows are extensive and well watered, and are pastured by numerous flocks and herds. The grain produce, consisting mainly of wheat, oats, rye, and Indian corn, considerably exceeds the consumption, and the vineyards yield an abundant supply of both white and red wines. Olives and almonds are also extensively cultivated, and the honey of Aude is much esteemed. Besides important manufactures of woollen and cotton cloths, combs, jet ornaments, and casks, there are paper-mills, distilleries, tanneries, and extensive iron and salt works. The chief town is Carcassonne, and the department is divided into the four arrondissements of Carcassonne, Limoux, Narbonne, and Castelnaudary. Population in 1872, 285,927.

AUDEBERT, JEAN BAPTISTE, a distinguished French naturalist and artist, was born at Rochefort in 1759. He studied painting and drawing at Paris, and gained considerable reputation as a miniature painter. In 1787 he was employed to make drawings of some objects in a natural history collection, and was also a contributor in the preparation of the plates for Olivier's *Histoire des Insectes*. He thus acquired a taste for the study of natural history, and devoted himself with great eagerness to the new pursuit. In 1800 appeared his first original work, *L'Histoire Naturelle des Singes, des Makis, et des Galéopithèques*, illustrated by 62 folio plates, drawn and engraved by himself. The colouring in these plates was unusually beautiful, and was laid on by a method devised by the author himself. Audebert died in 1800, but he had left complete materials for another great work, *Histoire des Colibris, des Oiseaux-Mouches, des Jacamares, et des Promerops*, which was published in 1802. 200 copies were printed in folio, 100 in large quarto, and 15 were printed with the whole text in letters of gold. Another work, left unfinished, was also published after the author's death, *L'Histoire des Grimpereaux, et des Oiseaux de Paradis.* The last two works also appeared together in two volumes with the title *Oiseaux dorés ou à reflets metalliques*, 1802.

AUDITOR, a person appointed to examine the accounts kept by the financial officers of the Crown, public corporations, or private persons, and to certify as to their accuracy. The multifarious statutes regulating the audit of public accounts have been superseded by the 29 and 30 Vict. c. 39, which gives power to the Queen to appoint a "comptroller and auditor-general," with the requisite staff to examine and verify the accounts prepared by the different departments of the public service. In examining accounts of the appropriation of the several supply grants, the comptroller and auditor-general "shall ascertain first whether the payments which the account department has charged to the grant are supported by vouchers or proofs of payments; and second, whether the money expended has been applied to the purpose or purposes for which such grant was intended to provide." The Treasury may also submit certain other accounts to the audit of the comptroller-general. All public moneys payable to the Exchequer are to be paid to the "account of Her Majesty's Exchequer" at the Bank of England, and daily returns of such payments must be forwarded to the comptroller. Quarterly accounts of the income and charge of the consolidated fund are to be prepared and transmitted to the comptroller, who, in case of any deficiency in the consolidated fund, may certify to the bank to make advances. The accounts of local boards, poor-law unions, &c., must be passed in a similar manner by an official auditor. It is the duty of the auditor to disallow all illegal payments, and surcharge them upon the person making or authorising them; but such disallowances may be removed by *certiorari* into the Court of Queen's Bench, or an appeal may be made to the local Government Board. In municipal corporations two burgesses must be chosen annually as auditors of the accounts.

English-speaking world amount to nearly £3,000,000 annually.

(*c*) In this connexion may be instanced the diffusion of the Bible in the world. The British and Foreign Bible Society was founded in 1804; the American Bible Society twelve years later; in 1891 these two societies were but two out of 80 Bible societies in the world. In 1800 the translations of the Bible were 47 in number; there are now 90 complete and 230 partial versions, making a total of 320 translations more or less complete.

(*d*) Evidence of the continuous growth of aggressive Christian energy may be found in the rapid increase of missionary bishoprics which has taken place of recent years. In the first half of the 19th century 23 new bishoprics were founded; in the latter half there were 69; the rate of increase was trebled in the second period. The same feature is shown in the Protestant Episcopal Church of America. During the 19th century it has added 73 new bishoprics, and 52 of these belong to the latter half of it. The two churches added to their organization 165 new sees in the same century, and no fewer than 73 of these have come into existence since 1870.

(*e*) But apart from figures, the whole position of Christian business has undergone a change in public estimation. Missionary meetings used to be dull, and missionary literature flat and insipid. Now all this is changed. Meetings are large and enthusiastic, and missionary literature displays a culture and breadth of treatment unknown to our fathers. The journals or magazines issued by societies treat of every land from Greenland to Patagonia, from Japan to the Southern Islands, and they set forth with intelligence and learning questions of geography, philology, sociology, art and science, native manners and customs, in addition to, or in illustration of, direct missionary information. The popular sympathy which so often waits on popular knowledge has been further enlisted by what are known as missionary loan exhibitions. In these vivid illustrations of native life and missionary work are given by means of costumes, curiosities, and models. To such an exhibition in Birmingham there were as many as 100,000 visitors; and everywhere similar exhibitions have been crowded.

As a witness to the changed popular feeling towards missionary enterprise, perhaps nothing can be more striking than the fact that there are now in England and America public monuments commemorating the zeal and devotion of the missionary. In Washington Square in New York there is a church which is a memorial to Judson the missionary; in Westminster Abbey there is a monument to David Livingstone, who lies in the ancient national shrine where the greatest of Englishmen are buried.

II. The Measure of Christian Progress in Matters not Reducible to Statistics.

(i.) *The Alleged Decline of Christian Influence.*—In estimating the present position and prospects of the Christian religion, it is necessary to refer to matters which are regarded by its friends and foes as tokens of its declining influence.

First, it is said that there are signs that Christianity has lost, or is losing, its moral influence. Ordinances and institutions which owe their sanctity to Christian influence are no longer socially observed. The Sunday, for instance, is being slowly transformed into a day of pleasure. Still more significant, it is alleged, is the lowering of moral standards: that which was once regarded as harmful is now treated as legitimate; the increase of luxury has led many to treat indulgences as though they were necessaries; the wish to live according to a liberal scale, and after an easeful fashion, has stimulated a passionate eagerness for wealth, and the determination to have it has led to a disregard of the code of honour, while the possession of the good things of life, as they are called, has produced enervation of character; restlessness, born of ease, has destroyed steadiness of habit; and impatience of toil has driven men to seek riches in doubtful rather than in diligent methods. In these ways, it is said, the claims of the Christian life are subordinated to the interests of the moment.

Against this must be set the fact that the apprehensions which here find expression have been common in all ages; they cannot be accepted as evidence of the declining influence of Christianity without some more tangible evidence. Earnestness, ambitious of greater Christian consistency, is always alive to contemporary evils. "The Lord's day is become the devil's market day" was the complaint of a bishop in 1724. Immorality at the same time was considered to be so rampant that men said, "Our light looks like the evening of the world." It is thus that men who measure public manners by the measure of their philanthrophic desires will ever speak. But for the purpose of the scientific historian, contemporary morals must be measured by a comparison of facts and statistics, and not by the despondency of the good. When, therefore, we find a steady diminution in pauperism and crime, and a marked increase of longevity owing to a more careful regard for human life and its conditions of health and happiness, we shall see that the advance of moral improvement is steady and sure, even if not rapid enough to satisfy the desires of the good. The most wholesome sign, under these circumstances, is the dissatisfaction of the good, for it is the witness that the spirit of earnestness and devotion is still a powerful factor in social life. When we quit the warm realms of zeal and enter the cold sphere of statistics, we find that the progress of moral standards advances with slow but decisive foot. The percentage of crime is strikingly lower; the paupers are proportionately fewer; greater care for the condition of the poor indicates a more tender public conscience. Social ambitions among us are becoming more unselfish. The general moral sense is higher. Intemperance is now a disgrace; slavery is illegal, and would be impossible to any enlightened Christian society. The ethical principles of Christianity have been planted deep among our social ideas, and have revolutionized manners. In our judgment, whatever undesirable features remain as blemishes on our civilization, the standards of moral life are gradually improving, and this improvement is largely due to the prevailing force of Christian ethics.

Secondly, it is said that everywhere men are increasingly reluctant to identify themselves with the Christian religion. Many discard the outward forms of Christian worship; attendance at worship is declining; and, perhaps most startling of all, the number of those who join the ranks of the Christian ministry is steadily diminishing among all Christian denominations. This last fact is the one which Christian churches should face: a searching inquiry into the causes for the decline of candidates for the ministry of the Church would be of the greatest interest. Till such inquiry has been made we can only speculate upon causes. Among these the following have been suggested:—(*a*) The unsettled condition of theological opinion, due to the progress of historical criticism. This is probably one cause, and it has given rise to the question how far the Christian churches should relax the terms of subscription required by their ministers. There can be no doubt that many of the dogmas to which subscription is required are, if not obsolete, yet expressed in terms which are at least incongruous with modern ideas.

for the great cost of the publication—leaving him, however, a very inadequate compensation for his extraordinary industry and skill. The first volume was published at New York in the end of the year 1830, the second in 1834, the third in 1837, and the fourth and last in 1839. The whole consists of 435 coloured plates, containing 1055 figures of birds the size of life. It is certainly the most magnificent work of the kind ever given to the world, and is well characterised by Cuvier, "C'est le plus magnifique monument que l'Art ait encore élevé à la Nature."

During the preparation and publication of his great work Audubon made several excursions from Great Britain. In the summer of 1828 he visited Paris, where he made the acquaintance of Cuvier, Humboldt, and other celebrated naturalists, and received from them every mark of honour and esteem. The following winter he passed in London. In April of 1830 he revisited the United States of America, and again explored the forests of the central and southern federal territories. In the following year he returned to London and Edinburgh, but the August of 1831 found him again in New York. The succeeding winter and spring he spent in Florida and South Carolina; and in the summer of 1832 he set out for the Northern States, with an intention of studying the annual migrations of birds, particularly of the passenger pigeon, of which he has given a striking description; but his career was arrested at Boston by a severe attack of cholera, which detained him there till the middle of August. After that he explored the coasts, lakes, rivers, and mountains of North America, from Labrador and Canada to Florida, during a series of laborious journeys, that occupied him for three years. From Charleston, accompanied by his wife and family, he took his third departure for Britain. During his earlier residence in Edinburgh he had begun to publish his *American Ornithological Biography*, which at length filled five large octavo volumes. The first was issued there by Adam Black in 1831; the last appeared in 1839. This book is admirable for the vivid pictures it presents of the habits of the birds, and the adventures of the naturalist. The descriptions are characteristically accurate and interesting.

In 1839 Audubon bade a final adieu to Europe; and returning to his native country, he published, in a more popular form, his *Birds of America*, in seven octavo volumes, the last of which appeared in 1844. His ardent love of nature still prompted him to new enterprises, and he set out on fresh excursions; but in these he was always accompanied by his two sons, and one or two other naturalists. The result of these excursions was the projection of a new work, *The Quadrupeds of America*, in atlas folio, and also a *Biography of American Quadrupeds*, both of which were commenced at Philadelphia in 1840. The latter was completed in 1850, and is, perhaps, even superior to his *Ornithological Biography*.

To great intelligence in observing, and accuracy in delineating nature, to a vigorous, handsome frame, and pleasing expressive features, Audubon united very estimable mental qualities, and a deep sense of religion without a trace of bigotry. His conversation was animated and instructive, his manner unassuming, and he always spoke with gratitude to Heaven for the very happy life he had been permitted to enjoy. He died, after a short illness, in his own residence on the banks of the Hudson, at New York, on the 27th of January 1851. See *Life and Adventures of J. J. Audubon the Naturalist*, edited, from materials supplied by his widow, by Robert Buchanan, London, 1868.

AUGEIAS (Αὐγείας, Αὐγέας, *cf.* ἡλίου αὐγή), in *Greek Legend*, a son of Helios, the sun. He was a prince of Elis, and, consistently with his being a descendant of the sun-god, had an immense wealth of herds, including twelve bulls sacred to Helios, and white as swans. He lived beside the stream Menios (Μήν=moon); and his daughter Agamede was, like Medeia and Circe, skilled in witchcraft, and connected with the moon goddess. The task of Hercules was to clear out all his stalls in one day, and without help. This he did by making an opening in the wall and turning the stream through them. Augeias had promised him a tenth of the herd, but refused this, alleging that Hercules had acted only in the service of Eurystheus.

AUGEREAU, Pierre François Charles, Duke of Castiglione, was the son of obscure parents, and born in 1757. After serving for a short period in the armies of France, he entered the Neapolitan service, and for some time supported himself by teaching fencing at Naples. In 1792 he joined the Republican army that watched the movements of Spain. He rose rapidly to the rank of brigadier-general, and commanded a division in the army of Italy. Here he distinguished himself in numerous engagements by his energy, skill, and vigorous rapidity of action. To him were due in great measure the brilliant victories of Millesimo, Dego, and Castiglione, and he led the decisive charges at the bloody combats of Lodi and Arcola. In 1797 he took part with Barras and the Directory, and was an active agent in the revolution of the 18th of Fructidor; but his jealousy of his former comrade, Bonaparte, prevented their intimacy; and he was one of the general officers not privy to the noted revolution of the 18th of Brumaire (Nov. 9) 1799. He received, however, the command of the army of Holland and the Lower Rhine, but was superseded in 1801. From that time he lived in retirement, till 1804, when he was made a marshal of the French empire, and in the following year he was appointed to the command of the expedition against the Vorarlberg, which he quickly subdued. He also distinguished himself greatly in the battles of Jena and Eylau. In 1809–10 he commanded the French in Catalonia, and tarnished his laurels by his great cruelty to the Spaniards; but he was again more honourably conspicuous in the campaign of 1813, especially in the terrible battle of Leipsic. In 1814 he had the command of a reserve army at Lyons, and might have made a diversion in favour of Napoleon, but he preferred to submit, and retained a command under the Bourbons. In the following year he at first refused to join Napoleon on his escape from Elba, and when he would afterwards have accepted a command his services were declined. He also failed to obtain military office under the new dynasty, and after having had the painful task of being one of the commission on the trial of Ney, he returned to his estates, where he died of dropsy in 1816.

AUGSBURG, a celebrated city of Germany, capital of the circle of Swabia and Neuburg in Bavaria, the principal seat of the commerce of South Germany, and of commercial transactions with the south of Europe. It derives its name from the Roman Emperor Augustus, who, on the conquest of Rhætia by Drusus, established a Roman colony named *Augusta Vindelicorum* (about 14 B.C.) In the 5th century it was sacked by the Huns, and afterwards came under the power of the Frankish kings. It was almost entirely destroyed in the war of Charlemagne against Thassilon, duke of Bavaria; and after the dissolution and division of that empire, it fell into the hands of the dukes of Swabia. After this it rose rapidly into importance as a manufacturing and commercial town, and its merchant princes, the Fuggers and Welsers, rivalled the Medici of Florence; but the alterations produced in the currents of trade by the discoveries of the 15th and 16th centuries occasioned a great decline. In 1276 it was raised to the rank of a free imperial city, which it retained, with many changes in its internal constitution, till 1806, when it was annexed to the kingdom of Bavaria. Meanwhile, it was

the scene of numerous events of historical importance. It was besieged and taken by Gustavus Adolphus in 1632, and in 1635 it surrendered to the imperial forces; in 1703 it was bombarded by the electoral prince of Bavaria, and forced to pay a contribution of 400,000 dollars; and in

the war of 1803 it suffered severely. Of its conventions the most memorable are those which gave birth to the Augsburg confession (1530) and to the Augsburg alliance (1686).

The city is pleasantly situated in an extensive and fertile plain, between the rivers Wertach and Lech, 36 miles W.N.W. of Munich, lat. 48° 21′ 44″ N., long. 10° 54′ 42″ E. Its fortifications were dismantled in 1703, and have since been converted into public promenades. Maximilian Street is remarkable for its breadth and architectural magnificence. One of its most interesting edifices is the Fugger House, of which the entire front is painted in fresco. Among the public buildings of Augsburg most worthy of notice is the town-hall, said to be one of the finest in Germany, built by Elias Holl in 1616–20. One of its rooms, called the "Golden Hall," from the profusion of its gilding, is 113 feet long, 59 broad, and 53 high. The palace of the bishops, where the memorable Confession of Faith was presented to Charles V., is now used for Government offices. The cathedral dates in its oldest portions from the 10th century. There are also various churches and chapels, a school of arts, a polytechnic institution, a picture gallery in the former monastery of St Catherine, a museum, observatory, botanical gardens, an exchange, gymnasium, deaf-mute institution, orphan asylum, public library, several remarkable fountains dating from the 16th century, &c. The "Fuggerei," built in 1519 by the brothers Fugger, consists of 106 small houses, let to indigent Roman Catholic citizens at a merely nominal rent. The manufactures of Augsburg are various and important, consisting of woollen, linen, cotton, and silk goods, watches, jewellery, and goldsmith-work, mathematical instruments, machinery, leather, paper, chemical stuffs, types, &c. Copper-engraving, for which it was formerly noted, is no longer carried on; but printing, lithography, and publishing have acquired a considerable development, one of the best-known Continental newspapers being the *Allgemeine Zeitung* or *Augsburg Gazette*. Augsburg is an important railway junction. On the opposite side of the river, which is here crossed by a bridge, lies the little village of Lechhausen. Population in 1871, 51,270.

AUGSBURG CONFESSION. See Creeds.

AUGURS, in *Roman Antiquities*, a college or board appointed to interpret, according to the books (*libri augurales*) in which the science of divination was laid down, the *auspicia* or signs of approval or disapproval sent by Jupiter on the occasion of any public transaction. At first, it is said, there were only two augurs, one from each of the tribes Ramnes and Tities. Two more were added by Numa, and again other two for the third tribe of Luceres, that is six altogether. But in the year 300 B.C. it is certain that there were only four, to which number five plebeian places were added by the *lex Ogulnia*. Sulla increased the number to fifteen, at which it continued, with the exception that Cæsar appointed a sixteenth, and the emperors frequently added as *supra numerum* persons of distinction, or of their own family. An augur retained his office and sacred character for life. The college had the right of election of new members. The insignia of their office were the *lituus*, or crook, and the dress called *trabea*. The natural region to look to for signs of the will of Jupiter was the sky, where lightning and the flight of birds seemed directed by him as counsel to men. The latter, however, was the more difficult of interpretation, and upon it, therefore, mainly hinged the system of divination with which the augurs were occupied, and which is expressed in the terms *augurium* and *auspicium* (*aves gerere, aves spicere*). The presence of augurs was required only in observing signs in the sky, where their first duty was to mark out with the *lituus* a space or *templum* in the sky within which the omen must occur. Such observations being properly made only in the city of Rome, augurs are not found elsewhere. Signs of the will of the gods were of two kinds, either in answer to a request (*auspicia impetrativa*), or incidental (*auspicia oblativa*). Of such signs there were five classes:— (1.) *Signs in the sky* (*cœlestia auspicia*), consisting chiefly of thunder and lightning, but not excluding falling stars and other phenomena. Lightning from left to right was favourable, from right to left unfavourable; and this being a very direct and impressive token of the will of Jupiter, the observation of it was held to apply to all public transactions fixed for the day on which it occurred. Whether favourable or the reverse in its direction, the appearance of lightning was held as a voice of the god against business being done in the public assemblies. But since the person charged to take the auspices (*de cœlo servasse*) for a certain day was constitutionally subject to no other authority who could test the truth or falsehood of his statement that he had observed lightning, it happened that this became a favourite means of putting off meetings of the public assembly. Restrictions were, however, imposed on it in the later times of the republic. When a new consul, prætor, or quæstor entered on his first day of office and prayed the gods for good omens, it was a matter of custom to report to him that lightning from the left had been seen. (2.) *Signs from birds* (*signa ex avibus*), with reference to the direction of their flight, and also to their singing, or uttering other

sounds. In matters of ordinary life on which divine counsel was prayed for, it was usual to have recourse to this form of divination. For public affairs it was, by the time of Cicero, superseded by the fictitious observation of lightning. (3.) *Feeding of birds* (*auspicia ex tripudiis*), which consisted in observing whether a bird,—usually a fowl,—on grain being thrown before it, let fall a particle from its mouth (*tripudium solistimum*). If it did so, the will of the gods was in favour of the enterprise in question. The simplicity of this ceremony recommended it for very general use, particularly in the army when on service. The fowls were kept in cages by a servant, styled *pullarius*. In imperial times are mentioned the *decuriales pullarii*. (4.) *Signs from animals* (*pedestria auspicia*, or *ex quadrupedibus*), *i.e.*, observation of the course of, or sounds uttered by, quadrupeds and serpents within a fixed space, corresponding to the observations of the flight of birds, but much less frequently employed. It had gone out of use by the time of Cicero. (5.) *Warnings* (*signa ex diris*), consisting of all unusual phenomena, but chiefly such as boded ill. Being accidental in their occurrence, they belonged to the *auguria oblativa*, and their interpretation was not a matter for the augurs, unless occurring in the course of some public transaction, in which case they formed a divine veto against it. Otherwise, reference was made for an interpretation to the Pontifices in olden times, afterwards frequently to the Sibylline books, or the Etruscan haruspices, when the incident was not already provided for by a rule, as, for example, that it was unlucky for a person leaving his house to meet a raven, that the sudden death of a person from epilepsy at a public meeting was a sign to break up the assembly, not to mention other instances of adverse omens. A Roman, however, did not necessarily regard a warning as binding unless it was clearly apprehended. Not only could an accidental oversight render it useless, but to some extent measures could be taken to prevent any warning being noticed. At sacrifices, for instance, the flute was played *ne quid aliud exaudiatur* (Pliny, *Nat. Hist.*, xxviii. 2, 11).

Among the other means of discovering the will of the gods were casting lots, oracles of Apollo (in the hands of the college *sacris faciundis*), but chiefly the examination of the entrails of animals slain for sacrifice. Anything abnormal found there was brought under the notice of the augurs as warnings, but usually the Etruscan haruspices were employed for this. The persons entitled to ask for an expression of the divine will on a public affair were the magistrates. To the highest offices, including all persons of consular and prætorian rank, belonged the right of taking *auspicia maxima;* to the inferior offices of ædile and quæstor, the *auspicia minora;* the differences between these, however, must have been small. The subjects for which *auspicia publica* were always taken were the election of magistrates, their entering on office, the holding of a public assembly to pass decrees, the setting out of an army for war. They could only be taken in Rome itself; and in case of a commander having to renew his *auspicia*, he must either return to Rome or select a spot in the foreign country to represent the hearth of that city. The time for observing auspices was, as a rule, between midnight and dawn of the day for which the transaction was fixed about which they were desired. But whether it was so ordered in the ritual, or whether this was to leave the whole day free, is not known. In military affairs this course was not always possible, as in the case of taking auspices before crossing a river. The founding of colonies, the beginning of a battle, before calling together an army, before sittings of the senate, at decisions of peace or war, were occasions, not always but frequently, for taking auspices. The place where the ceremony was performed was not fixed but varied, so as to have a close relation to the object to which it referred. A spot being selected, the official charged to make the observation (*spectio*) pitched his tent there some days before. A matter postponed through adverse signs from the gods could on the following or some future day be again brought forward for the auspices (*repetere auspicia*). If an error (*vitium*) occurred in the auspices, the augurs could, of their own accord or at the request of the senate, inform themselves of the circumstances, and decree upon it. A consul could refuse to accept their decree while he remained in office, but on retiring he could be prosecuted. *Auspicia oblativa* referred mostly to the comitia. A magistrate was not bound to take notice of signs reported merely by a private person, but he could not overlook such a report from a brother magistrate. For example, if a quæstor on his entry to office observed lightning and announced it to the consul, the latter must delay the public assembly for the day. (A. S. M.)

AUGUST, originally *Sextilis*, as being the sixth month in the pre-Julian Roman year, received its present name from the Emperor Augustus. The preceding month, *Quintilis*, had been called July after the great Julius Cæsar, and the senate thought to propitiate the emperor by conferring a similar honour upon him. August was selected, not as being the natal month of Augustus, but because in it his greatest good fortune had happened to him. In that month he had been admitted to the consulate, had thrice celebrated a triumph, had received the allegiance of the soldiers stationed on the Janiculum, had concluded the civil wars, and had subdued Egypt. As July contained thirty-one days, and August only thirty, it was thought necessary to add another day to the latter month, in order that Augustus might not be in any respect inferior to Julius.

AUGUSTA, the capital of the State of Maine, and seat of justice, is situated on the Kennebec River (in Kennebec county), 43 miles from its mouth, in lat. 44° 19′ N., long. 69° 50′ W. The city lies mainly on the right bank of the Kennebec River, which is here crossed by a bridge 520 feet long. The business portion of the city was destroyed by fire in 1865, but has since been rebuilt. Its principal public buildings are the State house, State insane asylum, and United States arsenal. It has several banks, daily and weekly newspapers, and numerous churches. The population of Augusta, by the census of 1870, was 7808.

AUGUSTA, a city of Georgia, in the United States of America, the capital of the county of Richmond. It is situated in a beautiful plain, on the Savannah River, 231 miles from its mouth, and has extensive railway communication. Like other American cities, it is spacious and regular in its plan, Greene Street, for example, being 168 feet in width, with a row of trees extending along each side. The principal buildings are the city hall, a masonic hall, an oddfellows' hall, the Richmond academy, the Georgia medical college, the opera-house, and an orphan asylum. Besides these, the city possesses an arsenal, water-works, a number of banks, newspaper offices, extensive cotton factories and flour mills, several foundries, two tobacco factories, &c. Water-power is abundantly supplied from the river by the Augusta canal, which was constructed in 1845. Augusta was an important place during the revolutionary war, and continued to flourish amazingly till the opening of the Georgia railway. A temporary decline then took place, owing to the change in the methods of traffic; but a new current of prosperity speedily set in, which still continues. Population in 1870, 15,386.

AUGUSTAN HISTORY is the title bestowed upon a collection of the biographies of the Roman emperors, from Hadrian to Carinus, written under Diocletian and Constan-

tine, and usually regarded as the composition of six authors,—Ælius Spartianus, Julius Capitolinus, Ælius Lampridius, Vulcatius Gallicanus, Trebellius Pollio, and Flavius Vopiscus. Upon investigation, however, there appears good reason for reducing these writers to four. The distribution of the respective biographies among them, according to the arrangement of the MSS., is supported by no extraneous authority, and depends upon no intelligible principle. Without entering into detail, for which space fails us, it must suffice to state that up to and including the biography of Alexander Severus, the authorship of the various memoirs is interchanged among Spartianus, Lampridius, and Capitolinus, in a manner only explicable upon the hypothesis of a division of labour among these writers, or on that of their having selected their subjects entirely at random. The latter is contradicted by their own affirmations, and no trace of any mutual concert is discoverable, neither is there any perceptible difference of style. When, therefore, we find the excerpts in the Palatine MS. assigning all the biographies preceding that of Maximin to Spartianus alone, and remark that his prænomen and that of Lampridius are alike given as Ælius, we cannot avoid suspecting with Casaubon and Salmasius that the full name was Ælius Lampridius Spartianus, and that two authors have been manufactured out of one. We further find Spartianus observing, at the commencement of his life of Ælius Verus, that having written the lives of all the emperors who had borne the title of Augustus from Julius Cæsar down to Hadrian, he purposes from that point to comprise the Cæsars also. This excludes the idea of his having written without a plan, or in concert with any colleague. His biographies are regularly dedicated to Diocletian down to that of Pescennius Niger, after which, with one exception, probably due to the corruption of the MSS., they are inscribed to Constantine, as would naturally be the case with a work continued under this prince's reign after having been commenced under his predecessor's. We may also with probability ascribe to Spartianus the life of Avidius Cassius, attributed in the MSS. to Vulcatius Gallicanus, but whose author describes his undertaking in terms almost identical with those employed by Spartianus. No biography subsequent to that of Alexander Severus is attributed to Spartianus by any MS., and the next series, comprising the Maximins, the Gordians, and Maximus and Balbinus, is undoubtedly the production of Julius Capitolinus, who addresses his work to Constantine, and professedly proceeds, in some respects, upon a different plan from his predecessor. The work of Spartianus must have remained incomplete, and Capitolinus must have proposed to fill up the interval between him and Trebellius Pollio, who dedicates his life of Claudius Gothicus to Constantius Chlorus, and whom we know, from the testimony of Vopiscus, to have written the lives of the Philippi and their successors up to Claudius, some years before 303 A.D. In that year (and not 291 A.D., as supposed by Salmasius and Clinton) Vopiscus was solicited by the urban prefect, Junius Tiberianus, to undertake the life of Aurelian; this biography appears from internal evidence to have been published by 307 A.D., and the lives of Aurelian's successors down to Carinus were added before the death of Diocletian in 313. We may therefore reduce the Augustan historians from six to four, and assign their respective shares as follows: To Spartianus, the biographies from Julius Cæsar to Alexander Severus, all anterior to Hadrian being lost; to Capitolinus, those from Maximin to the younger Gordian; to Trebellius Pollio, the lives of Valerian, Gallienus, the "Thirty Tyrants," and Claudius Gothicus, those of the Philippi, the Decii, Gallus, Æmilianus, and part of Valerian's being lost; to Vopiscus, the remainder, from Aurelian to Carinus. Some difficulty is created by the mention of Capitolinus, the latest biographer in order of composition, by his predecessor Vopiscus, but the passage may be an interpolation, or may refer to some other work.

The importance of the Augustan history as a repertory of information is very considerable, but its literary pretensions are of the humblest order. The writers' standard was confessedly low. "My purpose," says Vopiscus, "has been to provide materials for more eloquent persons than myself." Considering the perverted taste of the age, it is perhaps fortunate that the task fell into the hands of no showy declaimer, who measured his success by his skill in making surface do duty for substance, but of homely, matter-of-fact scribes, whose sole concern was to record what they knew. Their narrative is most unmethodical and inartificial; their style is tame and plebeian; their conception of biography is that of a collection of anecdotes; they have no notion of arrangement, no measure of proportion, and no criterion of discrimination between the important and the trivial; they are equally destitute of critical and of historical insight, unable to sift the authorities on which they rely, and unsuspicious of the stupendous social revolution comprised within the period which they undertake to describe. Their value, consequently, depends very much on that of the sources to which they happen to have recourse for any given period of history, and on the fidelity of their adherence to these when valuable. Marius Maximus and Junius Cordus, to whose qualifications they themselves bear no favourable testimony, were their chief authorities for the earlier lives of the series. For the later they have been obliged to resort more largely to public records, and have thus preserved matter of the highest importance, rescuing from oblivion many imperial rescripts and senatorian decrees, reports of official proceedings and speeches on public occasions, and a number of interesting and characteristic letters from various emperors. Their incidental allusions sometimes cast vivid though undesigned light on the circumstances of the age, and they have made large contributions to our knowledge of imperial jurisprudence in particular. Even their trivialities have their use; their endless anecdotes respecting the personal habits of the subjects of their biographies, if valueless to the historian, are most acceptable to the archæologist, and not unimportant to the economist and moralist. Their errors and deficiencies may in part be ascribed to the contemporary neglect of history as a branch of instruction. Education was in the hands of rhetoricians and grammarians; historians were read for their style, not for their matter, and since the days of Tacitus, none had arisen worth a schoolmaster's notice. We thus find Vopiscus acknowledging that when he began to write the life of Aurelian, he was entirely misinformed respecting the latter's competitor Firmus, and implying that he would not have ventured on Aurelian himself if he had not had access to the MS. of the emperor's own diary in the Ulpian library. The writers' historical estimates are superficial and conventional, but report the verdict of public opinion with substantial accuracy. The only imputation on the integrity of any of them lies against Trebellius Pollio, who, addressing his work to a descendant of Claudius, the successor and probably the assassin of Gallienus, has dwelt upon the latter versatile sovereign's carelessness and extravagance without acknowledgment of the elastic though fitful energy he so frequently displayed in defence of the empire. The caution of Vopiscus's references to Diocletian cannot be made a reproach to him.

No biographical particulars are recorded respecting any of these writers. From their acquaintance with Latin and Greek literature they must have been men of letters by profession, and very probably secretaries or librarians to persons of distinction. They appear particularly versed in

law. Spartianus's reference to himself as "Diocletian's own" seems to indicate that he was a domestic in the imperial household. They address their patrons with deference, acknowledging their own deficiencies, and seem painfully conscious of the profession of literature having fallen upon evil days.

The first edition of the *Augustan History* was printed at Milan in 1475, by Bonus Accursius, along with Suetonius. Being based upon the best MSS. it is superior to any of its successors until Casaubon's (1603). Casaubon manifested great critical ability in his notes, but for want of a good MS. left the restoration of the text to Salmasius (1620), whose notes are a most remarkable monument of erudition combined with acuteness in verbal criticism and general vigour of intellect. Little has since been done for the improvement of the text, which is still in a very unsatisfactory state. The most accurate edition is that by Jordan and Eyssenhardt (Berlin, 1863), grounded on a collation of the Bamberg MS. with the Palatine (now the Vatican) used by Salmasius. The most important separate dissertations on the Augustan historians are that on the sixth volume of Heine's *Opuscula Philologica;* Brocks's essay on the first four of them (Königsberg, 1869); Dirksen's elucidation of their references to Roman jurisprudence (Leipsic, 1842); Peter's critical emendations (Posen, 1863); Brunner's monograph on Vopiscus in the second volume of Büdinger's *Untersuchungen zur Römischen Kaisergeschichte*, and J. Müller's disquisition in the third (Leipsic, 1868-69). There is no English translation. (R. G.)

AUGUSTI, John Christian William, a distinguished German theologian, was born at Eschenberga, near Gotha, in 1772. He was of Jewish descent, his grandfather having been a rabbi who had been converted to the Christian faith. His early education he received partly from Moller, pastor of Gierstädt, who introduced him to the study of Hebrew, and partly at the gymnasium at Gotha. He then proceeded to the university of Jena, and completed his studies there in 1793. In 1798 he obtained a post as privat-docent, or university lecturer on philosophy, and began to turn his attention chiefly to Oriental subjects. In 1800 he was made professor extraordinary of philosophy, and three years after was appointed to the chair of Oriental languages. In 1808 he received the degree of doctor of theology, and in 1812 accepted a call to the chair of theology at the recently renovated university of Breslau. During the troubled years 1813 and 1814 he acted as rector, and received great praise for his firm and judicious conduct. In 1819 he was transferred to the university of Bonn, and in 1828 he united with his professorship the office of director of the consistory. He died at Coblentz in 1841. Augusti had little sympathy with the modern philosophical interpretations of dogma, and although he took up a position of free criticism with regard to the Biblical narratives, he yet held fast to the traditional faith. His works on theology (*History of Dogma*, 1805, and *System of Dogmatics*, 1809) are simple statements of fact, and do not attempt a speculative treatment of their subjects. In addition to several exegetical works, his most important writings are the *Denkwürdigkeiten aus der Christlichen Archäologie*, 12 vols., 1817-31, a partially digested mass of materials, and the *Handbuch der Christ. Archäologie*, 3 vols., 1836-7, which gives the substance of the larger work in a more compact and systematic form.

AUGUSTINE (Aurelius Augustinus), one of the four great fathers of the Latin Church, and admittedly the greatest of the four, more profound than Ambrose, his spiritual father, more original and systematic than Jerome, his contemporary and correspondent, and intellectually far more distinguished than Gregory the Great, the last of the series. The theological position and influence of Augustine may be said to be unrivalled. No single name has ever exercised such power over the Christian church, and no one mind ever made such an impression upon Christian thought.

Aurelius Augustinus was born at Tagaste (Tajelt), a town of Numidia, on the 13th of November 354 A.D. His father, Patricius, was a burgess of this town, and was still a pagan at the time of his son's birth. His mother, Monica, was not only a Christian, but a woman of the most elevated, tender, and devoted piety, whose patient prayerfulness for both her husband and son (at length crowned with success in both cases), and whose affectionate and beautiful enthusiasm, have passed into a touching type of womanly saintliness for all ages. She early instructed her son in the faith and love of Jesus Christ, and for a time her instruction seems to have impressed his youthful mind. Falling ill he wished to be baptised; but when the danger was past, the rite was deferred, and, notwithstanding all his mother's admonitions and prayers, he grew up without any profession of Christian piety, or any devotion to Christian principles. Inheriting from his father a vehement and sensual disposition, he early gave way to the unbridled impulses of passion, and while still a mere youth, formed a connection, common enough at the time, but at variance with the principles of Christian morality. As the result of the connection he became the father of a son, whom he named Adeodatus in a fit of pious emotion, and to whom he was passionately attached.

In the midst of all his youthful pleasures Augustine was an earnest student. His father, observing the early development of his talents, formed the ambition of training him to the brilliant and lucrative career of a rhetorician, and he seems to have spared no expense to equip him for this career. The youth studied not only at his native town, but at Madaura and Carthage, and especially devoted himself to the Latin poets—many traces of his love for which are to be found in his writings. His acquaintance with Greek literature was much more limited, and, indeed, it has been doubted whether he could use, in the original, either the Hebrew or Greek Scriptures.[1] Apparently, he was in the habit of using translations of Plato (*Confess.*, viii. 2), but, on the other hand, Greek words frequently occur in his writings correctly rendered and discriminated; and he speaks in one of his epistles to Marcellinus (LIX. tom. ii. 294) of referring to the Greek Psalter and finding, in reference to certain difficulties, that it agreed with the Vulgate. Clausen, who has particularly investigated the point, sums up the evidence to the effect that Augustine was "fairly instructed in Greek grammar, and a subtle distinguisher of words," but that beyond this his knowledge was insufficient for a thorough comprehension of Greek books, and especially for those in the Hellenistic dialect.

While a student at Carthage he was particularly attracted by the theatre, the spectacles at which were of unusual magnificence. To his enthusiastic and sensuous spirit they were irresistible, and the extent to which he seems to have yielded to the fascination is sufficient proof of his active alienation from Christianity at this period. The Christian church, as it has been said, "abhorred the pagan theatre. The idolatrous rites, the lascivious attitudes, the gladiatorial shows, which were its inseparable accompaniments, were equally opposed to the dogmatic monotheism, to the piety, and to the mercy of the gospel." One of the most significant signs of a man having become a Christian was his habitual absence from the theatre. No one was more emphatic on this point afterwards than Augustine himself, and as the result of his own experience, he seems to have doubted, apart from the gross immoralities of the pagan stage, whether the indulgence in fictitious joys and woes is a warrantable excitement (*Confess.*, iii. 2).

Cicero's *Hortensius*, which he read in his nineteenth year, first awakened in Augustine's mind the spirit of specula-

[1] "Augustinus extitit, ut alii, Ebrææ ac Græcæ linguæ ignarus." (Walch, *Bibl. Patrist.*, p. 352.) "Imperitus non tantum Hebraicæ sed etiam Græcæ linguæ, ipsos fontes adire non potuit, sed solam fere translationem Latinam explicare conatus est."—(Rosenmüller, *Hist. Interpret.*, iii. 40.)

tion. He engaged restlessly in philosophical studies, and passed from one phase of thought to another, unable to find satisfaction in any. Manichæism first enthralled him. Its doctrine of two principles, one of good and one of evil, seemed to answer to the wild confusion of his own heart, and the conflict of higher and lower impulses which raged within him. It seemed to solve the mysteries which perplexed him in his own experience and in the world. He became a member of the sect, and entered into the class of *auditors*. His ambition was to be received among the number of the *Elect*, and so get to the heart of what he believed to be their higher knowledge. But falling in with Faustus, a distinguished Manichæan bishop and disputant, and entering into discussion with him, he was greatly disappointed. The system lost its attraction for him; he gradually became disgusted, and abandoned it. But before this he had left Carthage, shocked with the licence of the students, and had betaken himself for a time to Rome in the pursuit of his profession. There he also soon became dissatisfied, and accepted an invitation to proceed to Milan, where the people were in search of a teacher of rhetoric. He travelled thither at the public expense, and was welcomed by friends who already seem to have recognised his distinction (*Confess.*, i. 16).

At Milan the conflict of his mind in search of truth still continued. He was now in his thirtieth year, and for eleven years he had been seeking for mental rest, unable to find it. "To-morrow," he said to himself, "I shall find it: it will appear manifestly, and I shall grasp it" (*Confess.*, vi. 18). But it still eluded his grasp, and he sunk back again into despondency. The way, however, was being prepared for his conversion. Ambrose was bishop of Milan, and, although he had a weak voice, was noted for his eloquence. Augustine was attracted by his reputation, and went to hear the famous Christian preacher in order, as he himself relates (*Confess.*, v. 23), "to see whether his eloquence answered what was reported of it. I hung on his words attentively," he adds, "but of the matter I was but an unconcerned and contemptuous hearer." He confesses his delight so far: "The bishop's eloquence was more full of knowledge, yet in manner less pleasurable and soothing, than that of Faustus." He wished an opportunity of conversation with him, but this was not easily found. Ambrose had no leisure for philosophic discussion. He was accessible to all who sought him, but never for a moment free from study or the cares of duty. "Augustine used to enter, as all persons might, without being announced; but after staying for a while, afraid of interrupting him, he departed again." He continued, however, to hear Ambrose preach, and gradually the gospel of divine truth and grace was received into his heart. First Plato and then St Paul opened his mind to higher thoughts, and at length certain words of the latter were driven home with irresistible force to his conscience. He was busy with his friend Alypius in studying the Pauline epistles. His struggle of mind became intolerable; the thought of divine purity fighting in his heart with the love of the world and of the flesh. He burst into an incontrollable flood of tears and rushed out into his garden, flinging himself under a fig tree that he might allow his tears to have full vent, and pour out his heart to God. Suddenly he seemed to hear a voice calling upon him to consult the divine oracle, "Take up and read, take up and read." He left off weeping, rose up, and sought the volume where Alypius was sitting, and opening it read in silence the following passage: "Not in rioting and drunkenness, not in chambering and wantonness, not in strife and envying. But put ye on the Lord Jesus Christ, and make not provision for the flesh to fulfil the lusts thereof" (Rom. xiii. 13, 14). He adds, "I had neither desire nor need to read farther. As I finished the sentence, as though the light of peace had been poured into my heart, all the shadows of doubt dispersed. Thus hast Thou converted me to Thee, so as no longer to seek either for wife or other hope of the world, standing fast in that rule of faith in which Thou so many years before hadst revealed me to my mother" (*Confess.*, viii. 30).

After his conversion, which is supposed to have occurred in the summer of 386, Augustine gave up his profession as a teacher of rhetoric, and retired to a friend's house in the country, in order to prepare himself for baptism. His religious opinions were still to some extent unformed, and even his habits by no means altogether such as his great change demanded. He mentions, for example, that during this time he broke himself off a habit of profane swearing, and in other ways sought to discipline his character and conduct for the reception of the sacred rite. He received baptism in Easter following, in his thirty-third year; and along with him his son Adeodatus and his friend Alypius were admitted to the Christian church. Monica, his mother, had rejoined him, and at length rejoiced in the fulfilment of her prayers. Dying before his return to his native country, her last hours were gladdened by his Christian sympathy. She implored him to lay her body anywhere, but wherever he might be to remember her "at the altar of the Lord," a devout duty which he invites others to share with him, so that her last request may, "through the prayers of many," receive a more abundant fulfilment.

Augustine went back to Rome for a short period and then returned to his native city, where he took up his abode in retirement, forming, with some friends who joined him in devotion, a small religious community, which looked to him as its head. They had all things in common, as in the early church, and fasting and prayer, Scripture reading and almsgiving, formed their regular occupations. Their mode of life was not formally monastic according to any special rule, but the experience of this time of seclusion was, no doubt, the basis of that monastic system which Augustine afterwards sketched, and which derived from him its name. Solitary monasticism had sprang up in the Egyptian deserts before this. The life of St Anthony by Athanasius had widely diffused the fervour for religious solitariness, and greatly touched Augustine at this period of his profession. It did not remain for him, therefore, to originate the monastic idea; but the association of monks in communities under a definite order and head received a special impulse both from Ambrose and his illustrious convert. As may be imagined, the fame of such a convert in such a position soon spread, and invitations to a more active ecclesiastical life came to him from many quarters. He shrank from the responsibility, but his destiny was not to be avoided. After three years spent in retirement he took a journey to Hippo, to see a Christian friend, who desired to converse with him as to his design of quitting the world and devoting himself to a religious life. He was the less reluctant to make this journey, because there being already a bishop at Hippo he hoped to escape all solicitation. But although the Christian community there had a bishop, they wanted a presbyter; and Augustine being present at the meeting called to choose a presbyter, the people unanimously chose him. He burst into tears, and would fain have escaped; but the church could not spare his services. He was ordained to the presbyterate, and in a few years afterwards he was made coadjutor to the bishop, and finally became sole bishop of the see.

Henceforth Augustine's life is filled up with his ecclesiastical labours, and is more marked by the series of his numerous writings and the great controversies in which they engaged him than by anything else. Already he had distinguished himself as an author. He had written several

philosophical treatises; he had combated the scepticism of the New Academy (*Contra Academicos libri tres*, 386 A.D.); he had treated of the "Blessed Life" (*De vita beata*, 386) and of the "Immortality of the Soul" (*De Immortalitate Animæ*, 387); he had defended the church against the Manichæans, whose doctrines he had formerly professed. "When I was at Rome," he says (*Retract.*, i. 7), "after my baptism, and could not hear in silence the vaunting of the Manichæans over true Christians, to whom they are not to be compared, I wrote two books, one on *The Morals of the Catholic Church*, and the other on *The Morals of the Manichæans.*" These tracts or pamphlets, for they are little more, were written in the year 388, about two years after his conversion. Later, in 395, and again in 400, he pursued the controversy with the Manichæans, making an elaborate reply, in the latter year, to his old associate and friend Faustus. The reply was provoked by an attack made by Faustus on the Catholic faith, which the "brethren" invited Augustine to answer. This he did characteristically and energetically by giving in succession "the opinions of Faustus, as if stated by himself," and his own in response. It was natural that the Manichæan heresy, which had so long enslaved his own mind, should have first exercised Augustine's great powers as a theological thinker and disputant. He was able from his own experience to give force to his arguments for the unity of creation and of spiritual life, and to strengthen the mind of the Christian church in its last struggle with that dualistic spirit which had animated and moulded in succession so many forms of thought at variance with Christianity.

But the time was one of almost universal ecclesiastical and intellectual excitement; and so powerful a mental activity as his was naturally drawn forth in all directions. Following his writings against the Manichæans come those against the Donatists. This controversy was one which strongly interested him, involving as it did the whole question of the constitution of the church and the idea of catholic order, to which the circumstances of the age gave special prominence. The Donatist schism sprang out of the Diocletian persecutions in the beginning of the century. A party in the Church of Carthage, fired with fanatical zeal on behalf of those who had distinguished themselves by resistance to the imperial mandates and courted martyrdom, resented deeply the appointment of a bishop of moderate opinions, whose consecration had been performed, they alleged, by a *traditor*. They set up, in consequence, a bishop of their own, of the name of Majorinus, succeeded in 315 by Donatus. The party made great pretensions to purity of discipline, and rapidly rose in popular favour, notwithstanding a decision given against them both by the bishop of Rome and by the Emperor Constantine, to whom they personally appealed. Augustine was strongly moved by the lawlessness of the party, and launched forth a series of writings against them, the most important of which survive, though some are lost. Amongst these are *Seven Books on Baptism*, and a lengthened answer, in three books, to Petilian, bishop of Cirta, who was the most eminent theologian amongst the Donatist divines. At a somewhat later period, about 417, he wrote a treatise concerning the correction of the Donatists (*De Correctione Donatistarum*), "for the sake of those," he says in his *Retractations*, ii. c. 48, "who were not willing that the Donatists should be subjected to the correction of the imperial laws." In these writings, while vigorously maintaining the validity of the Catholic Church as it then stood in the Roman world, and the necessity for moderation in the exercise of church discipline, Augustine yet gave currency, in his zeal against the Donatists, to certain maxims as to the duty of the civil power to control schism, which were of evil omen, and have been productive of much disaster in the history of Christianity.

The third controversy in which Augustine engaged was the most important, and the most intimately associated with his distinctive greatness as a theologian. As may be supposed, from the conflicts through which he had passed, the bishop of Hippo was intensely interested in what may be called the anthropological aspects of the great Christian idea of redemption. He had himself been brought out of darkness into "marvellous light," only by entering into the depths of his own soul, and finding, after many struggles, that there was no power but divine grace, as revealed in the life and death of the Son of God, which could bring rest to human weariness, or pardon and peace for human guilt. He had found human nature in his own case too weak and sinful to find any good for itself. In God alone he had found good. This deep sense of human sinfulness coloured all his theology, and gave to it at once its depth—its profound and sympathetic adaptation to all who feel the reality of sin—and that tinge of darkness and exaggeration which as surely have repelled others. When the expression Augustinianism is used, it points especially to those opinions of the great teacher which were evoked in the Pelagian controversy, to which he devoted the most mature and powerful period of his life. His opponents in this controversy were Pelagius, from whom it derives its name, and Cœlestius and Julianus, pupils of the former. Pelagius was a British monk. Augustine calls him Brito; and Jerome points to his Scottish descent, in such terms, however, as to leave it uncertain whether he was a native of Scotland or Ireland (*habet progeniem Scotiæ gentis de Britannorum vicinia*). He was a man of blameless character, devoted to the reformation of society, full of enthusiasm, and that confidence in the natural impulses of humanity which often accompanies philanthropic enthusiasm. Travelling to Rome about the beginning of the 5th century, he took up his abode for a time there, and soon made himself conspicuous by his activity and opinions. His pupil Cœlestius carried out the views of his master with a more outspoken logic, and was at length arraigned before the bishop of Carthage, for the following, amongst other, heretical opinions:—(1.) That Adam's sin was purely personal, and affected none but himself; (2.) That each man, consequently, is born with powers as incorrupt as those of Adam, and only falls into sin under the force of temptation and evil example; (3.) That children who die in infancy, being untainted by sin, are saved without baptism. Views such as these were obviously in conflict with the whole course of Augustine's experience, as well as with his interpretation of the catholic doctrine of the church. And when his attention was drawn to them by the trial and excommunication of Cœlestius, he undertook their refutation, first of all, in three books on *Forgiveness of Sins and Baptism*, addressed to his friend Marcellinus, in which he vindicated the necessity of the baptism of infants because of original sin and the grace of God by which we are justified (*Retract.*, ii. c. 23). This was in 412. In the same year he addressed a further treatise to the same person, "My beloved son Marcellinus," on *The Spirit and the Letter*. Three years later he composed two further treatises on *Nature and Grace*, and the relation of the *Human to the Divine Righteousness*. The controversy was continued during many years in no fewer than fifteen treatises. Upon no subject did Augustine bestow more of his intellectual strength, and in relation to no other have his views so deeply and permanently affected the course of Christian thought. Even those who most usually agree with his theological stand-point will hardly deny that, while he did much in these writings to vindicate divine truth and to expound the true relations of the divine and human,

he also, here as elsewhere, was hurried into extreme expressions as to the absoluteness of divine grace and the extent of human corruption. Like his great disciple in a later age—Luther—Augustine was prone to emphasise the side of truth which he had most realised in his own experience, and, in contradistinction to the Pelagian exaltation of human nature, to depreciate its capabilities beyond measure. There are few thoughtful minds who would not concede the deeper truthfulness of Augustine's spiritual and theological analysis, in comparison with that of his opponent, as well as its greater consistency with Scripture; but there are also few who would now be disposed to identify themselves with the dogmatism of the orthodox bishop any more than with the dogmatism of the heretical monk. And on one particular point, which more or less runs through all the controversy—the salvation of infants—the Christian consciousness, in its later and higher growth, may be said to have pronounced itself decisively on the side of the monk rather than of the bishop.

In addition to these controversial writings, which mark the great epochs of Augustine's life and ecclesiastical activity after his settlement as a bishop at Hippo, he was the author of other works, some of them better known and even more important. His great work, the most elaborate, and in some respects the most significant, that came from his pen, is *The City of God.* It is designed as a great apologetic treatise in vindication of Christianity and the Christian church,—the latter conceived as rising in the form of a new civic order on the crumbling ruins of the Roman empire,—but it is also, perhaps, the earliest contribution to the philosophy of history, as it is a repertory throughout of his cherished theological opinions. This work and his *Confessions* are, probably, those by which he is best known, the one as the highest expression of his thought, and the other as the best monument of his living piety and Christian experience. *The City of God* was begun in 413, and continued to be issued in its several portions for a period of thirteen years, or till 426. The *Confessions* were written shortly after he became a bishop, about 397, and give a vivid sketch of his early career. To the devout utterances and aspirations of a great soul they add the charm of personal disclosure, and have never ceased to excite admiration in all spirits of kindred piety. His systematic treatise on *The Trinity*, which extends to fifteen books, and occupied him for nearly thirty years, must not be passed over. "I began," he says (*Retract.*, ii. 15), "as a very young man, and have published in my old age some books concerning the Trinity." This important dogmatic work, unlike most of his dogmatic writings, was not provoked by any special controversial emergency, but grew up silently during this long period in the author's mind. This has given it something more of completeness and organic arrangement than is usual with him, if it has also led him into the prolonged discussion of various analogies, more curious than apt in their bearing on the doctrine which he expounds. The exegetical writings of Augustine,—his lengthened *Commentary on St John* and on the *Sermon on the Mount*, &c.,—and then his *Letters*, remain to be mentioned. The former have a value from his insight into the deeper spiritual meanings of Scripture, but hardly for their exegetical characteristics. The latter are full of interest in reference to many points in the ecclesiastical history of the time, and his relation to contemporary theologians like Jerome. They have neither the liveliness nor variety of interest, however, which belong to the letters of Jerome himself. The closing years of the great bishop were full of sorrow. The Vandals, who had been gradually enclosing the Roman empire, appeared before the gates of Hippo, and laid siege to it. Augustine was ill with his last illness, and could only pray for his fellow-citizens. He passed away during the progress of the siege, on the 28th of August 430, at the age of seventy-five, and was spared the indignity of seeing the city in the hands of the enemy.

The character of Augustine, both as a man and a theologian, has been briefly indicated in the course of our sketch. Little remains to be added without entering into discussions too extended for our space. None can deny the greatness of Augustine's soul—his enthusiasm, his unceasing search after truth, his affectionateness, his ardour, his self-devotion. And even those who may doubt the soundness or value of some of his dogmatic conclusions, cannot hesitate to acknowledge the depth of his spiritual convictions, and the strength, solidity, and penetration with which he handled the most difficult questions, and wrought all the elements of his experience and of his profound Scriptural knowledge into a great system of Christian thought.

The best complete edition of Augustine's writings is that of the Benedictines, in 11 vols. folio, published at Paris, 1679–1800, and reprinted in 1836–38 in 22 half-volumes. Tillemont, in his *Ecclesiastical History*, has devoted a quarto volume to his life and writings. Two extensive monographs have appeared on him; the one by Kloth, a Roman Catholic (Aachen, 1840), and the other by Bindemann, a Protestant (Berlin, 1844, 1855). See also Ritter's *Hist. of Christian Philosophy*, vol. i.; Böhringer's *Hist. of the Church;* Dr P. Schaff's *St Augustine* (Berlin, New York, and London, 1854); Nourrisson, *La Philosophie de S. Augustine* (Paris, 1866); A. Dorner, *Augustinus* (Berlin, 1872); Neander's *Church History;* Mozley's *Augustinian Doctrine of Predestination*, 1855; Jameson's *Sacred and Legendary Art.* (J. T.)

AUGUSTINE, or AUSTIN, ST, the first archbishop of Canterbury, was originally a monk in the Benedictine convent of St Andrew at Rome, and was educated under the famous Gregory, afterwards Pope Gregory I., by whom he was sent to Britain with forty monks of the same order, to carry out the favourite project of converting the English to Christianity. The missionaries set out with much reluctance, for the journey was long and perilous, and on the way they endeavoured to persuade the Pope to allow them to return. His orders, however, were peremptory; they proceeded, therefore, on their journey, and at last landed, some time in the year 596, on the isle of Thanet. Having sent interpreters to explain their mission to King Ethelbert, whose queen, Bertha, was a Christian, they received from him permission to preach and to make converts. He treated them with great favour, held a public conference with them, and assigned them a residence at Durovernum, now Canterbury. His own conversion to the Christian faith, which took place shortly afterwards, had a powerful influence with his subjects, who joined the new church in great numbers. Augustine, seeing the success of his labours, crossed to France, and received consecration at Arles. He then despatched messengers to the Pope to inform him of what had been done, and to propose for his consideration certain practical difficulties that had arisen. They brought back the *pallium*, with which Augustine was consecrated as first archbishop of Canterbury, and certain vestments and utensils for the new churches. Gregory also gave most prudent counsel for dealing with the new converts, strongly advising the archbishop to make the change of faith, so far as ceremonial went, as gradual as possible, and not on any account to wound the feelings of the people by destroying their temples, but rather to consecrate them afresh, and use them for Christian worship. Augustine passed the remainder of his life principally at Canterbury, where he died, probably in 607, on the 26th May. See *Lives of the English Saints*, No. III. 1847, and Mrs Jameson's *Legends of the Monastic Orders.*

AUGUSTINIANS, a monastic order of the Roman Catholic Church, claiming to have received its rule from St Augustine. See ABBEY and MONASTICISM.

AUGUSTOVO, a city in Russian Poland, in the government of Suvalki, situated on the river Netta, near a lake, which abounds in fish. It was founded in 1557 by Sigismund II. (Augustus), and is laid out in a very regular manner, with a large market-place. It carries on a large trade in cattle and horses, and manufactures linen and huckaback. Population, 9383.

AUGUSTUS AND THE AUGUSTAN AGE. The name of Augustus was the title of honour given by the Romans to the emperor Caius Julius Cæsar Octavianus, or, as he was originally designated, Caius Octavius. This title was intended to be hereditary in his family, but all the succeeding Cæsars or emperors of Rome continued to adopt it, long after they had ceased to be connected with the first Augustus by blood. The era of Augustus formed an illustrious epoch in Roman history, and was distinguished for its splendid attainments in arts and arms, and more especially in literature. The Romans in later times looked back to the age of Augustus with great complacency, as the most prosperous and the most distinguished in their annals. The name of the "Augustan Age" has been specially applied to it in modern times, and the same title has been given, with more or less justice, to certain epochs in modern history as the highest compliment to their glory. The reign of Louis XIV. is called the Augustan age of France; the reign of Anne, the Augustan age of England.

Personal history of Augustus.

Caius Octavius was the son of a noble Roman of the same name, of the plebeian order. The father had married Atia, the daughter of Julia, sister to the great C. Julius Cæsar, who was accordingly great-uncle to the young Octavius. Cæsar, the dictator, having no son of his own, took an interest in this youth, caused him to be enrolled among the Patricians, and bred him with a view to the highest honours of the republic. Already, in his eighteenth year, he had chosen him for his "master of the horse," but this was a merely nominal distinction. The young man was sent to carry on his education at the camp at Apollonia in Illyricum, and there, at the age of nineteen, he heard of his great kinsman's assassination (44 B.C.). He had already become a favourite with the soldiers, who offered to escort him to Rome, and follow his fortunes. But this he declined, and crossed over alone to Italy. On landing he learnt that Cæsar had made him his heir and adopted him into the Julian gens, whereby he acquired the designation of C. Julius Cæsar Octavianus. The inheritance was a perilous one; his mother and others would have dissuaded him from accepting it, but he, confident in his abilities, declared at once that he would undertake its obligations, and discharge the sums bequeathed by the dictator to the Roman people. M. Antonius had possessed himself of Cæsar's papers and effects, and made light of his young nephew's pretensions. The liberators paid him little regard, and dispersed to their respective provinces. Cicero, much charmed at the attitude of Antonius, hoped to make use of him, and flattered him to the utmost, with the expectation, however, of getting rid of him as soon as he had served his purpose. Octavianus conducted himself with consummate adroitness, making use of all competitors for power, but assisting none. Considerable forces attached themselves to him. The senate, when it armed the consuls against Antonius, called upon him for assistance; and he took part in the campaign in which Antonius was defeated at Mutina, but both the consuls, Hirtius and Pansa, slain. The soldiers of Octavianus demanded the consulship for him, and the senate, though now much alarmed, could not prevent his election. He now effected a junction with Antonius, who quickly overthrew the power of the republican party in their stronghold, the Cisalpine provinces, with the death of Decimus Brutus, the ablest of the liberators. Thereupon Octavianus and Antonius, taking Lepidus into union with them, met on the river Rhenus near Bononia, and proclaimed themselves a triumvirate for the reconstitution of the commonwealth. They divided the western provinces among them, the east being held for the republic by M. Brutus and Cassius. They drew up a list of proscribed citizens, entered Rome together, and caused the assassination of three hundred senators and two thousand knights. They further confiscated the territories of many cities throughout Italy, and divided them among their soldiers. Cicero was murdered at the demand of Antonius. The remnant of the republican party took refuge either with Brutus and Cassius in the East, or with Sextus Pompeius, who had made himself master of the seas.

Octavianus and Antonius crossed the Adriatic in 42 B.C. to reduce the last defenders of the republic. Brutus and Cassius were defeated, and fell at the battle of Philippi. War soon broke out between the victors, the chief incident of which was the siege and capture by famine of Perusia, and the alleged sacrifice of three hundred of its defenders by the young Cæsar at the altar of his uncle. But peace was again made between them. Antonius married Octavia, his rival's sister, and took for himself the eastern half of the empire, leaving the west to Cæsar. Lepidus was reduced to the single province of Africa. Meanwhile Sextus Pompeius made himself formidable by cutting off the supplies of grain from Rome. The triumvirs were obliged to concede to him the islands in the western Mediterranean. But Octavianus could not allow the capital to be kept in alarm for its daily sustenance. He picked a quarrel with Sextus, and when his colleagues failed to support him, undertook to attack him alone. Antonius, indeed, came at last to his aid, in return for military assistance in the campaign he meditated in the East. But Octavianus was well served by the commander of his fleet, M. Vipsanius Agrippa. Sextus was completely routed, and driven into Asia, where he perished soon afterwards. Lepidus was an object of contempt to all parties, and Octavianus and Antonius remained to fight for supreme power.

The alliance of Antonius with Cleopatra, queen of Egypt, alienated the Romans from him. They now gladly accepted the heir of Cæsar as the true successor of the most illustrious of their heroes. It was felt almost universally that the empire required a single head, and that repose could only be assured by the sovereignty of the chief of its armies. The battle of Actium, followed by the death of Antonius, 31 B.C., raised the victor to universal empire. Nevertheless, Octavianus did not hasten to assume his position. He first regulated the affairs of Egypt, which he annexed to the Roman dominions, then lingered for a time in Greece, and entered upon a fifth consulship at Samos, 29 B.C. On his return to Rome he distributed the vast sums he had accumulated among the people and the soldiers, while he soothed the pride of the nobles by maintaining unchanged the outward show of republican government. Of his personal history from this period there remains little to be said. He continued to reside almost constantly at Rome and in the neighbourhood, making one expedition into Spain, 27 B.C., and a journey through Greece in 21, on which occasion he advanced into Syria, and received back the standards taken by the Parthians from Crassus. In 16 B.C. he went to Gaul to regulate the affairs of that province, an expedition which he repeated, 9 B.C. But from thenceforth he intrusted the defence of the position to his lieutenants, and more especially to the young princes of his own family. The empire continued to enjoy profound internal tranquillity. More than one plot was formed against the head of the state by some of the discontented nobility, but these were discovered and disconcerted; and when it was evident that they met with no favour from the people generally, he

could afford to treat them with a signal clemency, which seems to have secured him from any further attempts. The serenity and placability which he displayed in his latter years forms a marked contrast to his jealousy and ferocity at an earlier period; and the character of the Emperor Augustus Cæsar has been a problem to historians in consequence. The life of the emperor was prolonged to the year 14 A.D. He died at Nola in his seventy-fifth year, after holding supreme power in the state for nearly half a century.

His policy and government.

During the years which had intervened between his accepting the inheritance of Cæsar, and his attaining to Cæsar's undivided sovereignty, the young aspirant had been meditating how to secure the retention of his power. At first, excited by fears for his own personal safety, and urged by the examples of party leaders around him, and of others who had gone before him, he plunged into a career of wholesale bloodshed, and cut off without scruple every public man from whose principles or whose passions he might have cause of apprehension. A large proportion, perhaps, of the senators and nobles had perished in the proscriptions and bloody wars of the triumvirate. Still it could not be expected that the germs of republican sentiment would ever be wholly eradicated. The sense of patriotism and the sense of interest would not fail to raise up enemies to the sovereign ruler of the Roman commonwealth. The conqueror's first object was to protect himself by force of arms, his next to soothe the passions of the class from whose resentment he had most cause of fear, and after that to raise up another class in direct sympathy with himself to balance the power which the first must necessarily retain in a well-ordered government. It was to the attainment of these three objects that Octavianus directed his organisation of the commonwealth.

Imperator.

The powers of the imperator or commander of the Roman army ceased on his return to the city. He then became once more a plain citizen. If war again arose he must seek his reappointment to command with the usual forms. Cæsar had not trusted his countrymen so far. He had claimed from them the title of imperator in perpetuity. With this title prefixed to his name, he continued to be still the commander of the legions, whether in the city or in the provinces. With this power his successor dared not dispense. On his arrival at Rome from the East he at once required the senate to accord it to him, as to his uncle before him; but he pretended only to ask it for a limited period of five years. At the expiration of that term, however, he assumed it again and again, though each time for ten years only, but never actually relinquished it to the end of his career. He thus received authority to command the whole force of the state in chief, and the officers who acted under him became simply his lieutenants. If they gained victories, the honours of the triumph were reserved for the imperator "under whose auspices" they were reputed to have served. It followed that all the provinces on the frontiers, or in which armies were maintained, were placed under the emperor's direct authority, while it was only the central and peaceful portions of the empire that were handed over to the government of the senate. The imperial provinces were administered by the legati Cæsaris, the senatorial by proconsuls.

The person of the emperor was thus secured as far as the power of the sword could secure it. But he was anxious that the source of this power should not be too apparent. The second Cæsar wished to maintain the appearance at least of government by the constitutional powers of the republic. The senate had once been practically the ruling power, as far as it was not actually controlled by the masters of the legions. He would not degrade it in its own estimation, or in the estimation of the people, any further, at least, than might be necessary for his main object. He caused himself to be appointed censor, not for one but for five years, in order to give him full time to revise the list of senators, to supply the fearful gaps in the ranks of the old nobility, and to expel such members, and many they were, who seemed unworthy, from their foreign extraction, their low birth, their scanty means, or their bad character, to have a place in that august assembly. The irregularities of the epoch which he hoped now to close had filled its benches with personages who degraded the order in the eyes of genuine citizens. The nobles and good citizens generally hailed this revision with deep satisfaction. It accorded with the national taste as well as with historical traditions. From the individual resentments it provoked, it was an act of some personal danger to the censor; but the danger was more than repaid by the popularity attending upon it, which was enhanced to the utmost by the liberality with which provision was made for raising some of the poor but honourable members of the order to the standard of property now to be required of them.

Princeps Senatus.

The emperor placed himself at the head of this reconstituted body, by assuming the office and title of *Princeps Senatus*. The office was indeed little more than nominal; it gave the right of proposing measures and of speaking first in the highest legislative assembly of the state, and having been borne in earlier times by some of the most distinguished of Roman patriots, it carried with it the respect and affection of the people. The titular precedence it gave was all the more valuable, inasmuch as it might be conceded without a blush by the sturdiest republican in the senate. But it was the consul who possessed practically the chief authority in the assembly. Octavianus had been already five times consul, and he shrank from seizing in perpetuity an office which, according to Roman ideas, differed in nothing from royalty, except that it was elective, and that it was limited to the tenure of a single year. Yet he could hardly afford to yield it to the citizen whom the people might at any time elect to thwart or to rival him. What should he do? He took what was certainly a bold step. It was a manifest innovation upon the forms of the free state when he required from the citizens the perpetual "potestas," or power of the consulship, at the same moment that he resigned the office itself, and suffered consuls to be annually elected to sit, one on each side of him, in the senate. The potestas which was thus conceded to him rendered him the head of the state, both in its legislative and executive departments. When he quitted the city he carried with him into the provinces a proconsular authority, and became to all intents and purposes king for life of the Romans and of their subjects. Even in the senatorial provinces he was now recognised as supreme; and thus it was that in him were centred all the great political functions which had been hitherto divided by the great assembly of the Roman magnates.

Assumption of potestas.

But the emperor did not limit his views to becoming the chief of the nobles. It was the part of a wary statesman to associate himself not less intimately with the opposite faction, which, under the name of the plebeians, had aimed at securing co-ordinate power with the patricians. The original meaning of these designations had indeed long been lost. The plebeians could boast many families as eminent both for honours and possessions as their haughty rivals. Step by step they had won an equal share with them in political privileges. But the class which still bore the title of plebeian was much more widely extended, and embraced the great mass of the knights and men of business in the city, and also of the citizens settled throughout the provinces. This large class had for more than a century contended with the nobles for the perquisites of office, and their mutual rivalry had

armed Sulla against Marius and Cæsar against Pompeius. The heir of Cæsar inherited the favour of the plebeians, and was bound to requite it by distinguished patronage. The plebeians were still the electors to the tribunate, and still regarded the tribunes as their protectors against the encroachments of the patricians represented by the senate. The tribunes had proved themselves most useful allies to Cæsar, and might yet again array themselves in support of the faithful inheritor of his principles. The emperor proposed to balance the consular potestas by assuming at the same time a tribunician potestas also. He thus endowed himself with the authority of the tribune for life, and assured the commons of the city and empire that he could at any time exercise the formidable veto upon the proceedings of the consuls which had served them so well, even down to recent times. Thus did he become emperor indeed,—the sovereign both of the nobles and the people in the city, as well as the commander of the army in the field and in the provinces.

There remained yet another sovereign authority in the state, namely, that which the chief pontiff exercised over the affairs of religion. However much the religious sentiment had been weakened throughout the Roman world, there was yet enough superstition left among the citizens to confer great and sometimes overwhelming influence upon the legitimate interpreter of divine things to the nation. The senate had exercised this power with great effect, as long as the appointment to the chief pontificate rested with the patrician curiæ. Of late years, however, this important dignity had been thrown open to the commons also. Octavianus was well pleased to accept it on the nomination of the whole people combined. He allowed, indeed, his former colleague Lepidus to retain it unmolested during his lifetime, but upon his death he assumed himself the exalted position which he might hesitate to intrust to any other. With this last addition to his prerogatives the emperor might well be content. The name of king he had from the first utterly repudiated. The office of dictator approached too near to that of a king to be acceptable to a ruler, who studied to confine himself within the limits of the republican constitution. Yet there still lacked some general appellative which might reflect in a single word the full dignity and power resulting from the combination of so many honours and prerogatives. The emperor proposed at first, it is said, to assume the name of *Romulus;* but Romulus had been a king; and further, Romulus had been destroyed, according to the tradition, by the senate, just as Cæsar had been in later times. Such associations were ominous. At last he fixed upon the epithet *Augustus*, a name which no man had borne before, and which, on the contrary, had been applied to things the most noble, most venerable, and most sacred. The rites of the gods were called *august;* their temples were *august.* The word itself was derived from the holy *auguries;* it was connected in meaning with the abstract term *authority*, and with all that increases and flourishes upon earth. The use of this glorious title could not fail to smooth the way to the general acceptance of the divine character of the mortal who was deemed worthy to bear it. The senate had just decreed the divinity of the defunct Cæsar; the courtiers were beginning now to insinuate that his successor, while yet alive, enjoyed an effluence from deity; the poets were even suggesting that altars should be raised to him; and in the provinces, among the subjects of the state at least, temples to his divinity were actually rising, and the *cult* of Augustus was beginning to assume a name, a ritual, and a priesthood.

Chief pontiff.

The title Augustus.

Religious sentiment of the age

Augustus, as we may now call him, viewed all this with secret satisfaction. It was one of his first objects, indeed, to restore the outward show at least of reverence for divine things, and re-establish the old Roman religion on its firm political basis. It was easy to rebuild, or cause to be rebuilt, the fallen or dilapidated temples of the national gods. The nobles paid their court to their master by seconding his efforts in this direction. The Pantheon, the temple of all the gods, if such was its original destination, remains still as a monument of his minister Agrippa's munificence; but Virgil would assure us that not less than three hundred "grand" temples were erected throughout the city. Perhaps, indeed, these were mostly the sacella or chapels of the Lares, which are placed at the corners of the streets. Augustus took the sentiment of the people at a favourable moment. They were thoroughly sickened by the miseries of the civil wars; they were ashamed of the crimes for which the whole nation were more or less responsible; they were eager to rush into any scheme of expiation and reparation that should be offered to them, and lend their hands to the material work of restoring at least the outward semblance of penitence for sin, and thankfulness for the mercy vouchsafed them. There can be no doubt that the conscience of the nation was awakened to a sense of the divine retribution under which they had suffered, but which had been at last averted under the blessed influence of the ruler whom they had at last chosen. The Romans had not lost their belief in a divine Providence, which oppressed them with anxiety and terror, however little they connected it with a sense of moral duty.

The spirit of materialistic philosophy had, however, been rife among them, and during the past century the anti-religious dogmas of Epicurus had sapped the belief of the educated and literary classes. The patrician youth of Rome had been trained in the schools of Greece, and especially at Athens, or had been placed under the teaching of Greek instructors at home; and of the three contending schools, the Stoics, the Epicureans, and the Academics, the second was that which had carried off far the greater number of disciples. The men of books or of speculative character might be generally Academics, and claim Cicero as their noblest leader; the men of imagination and deep religious fervour might follow, with Cato and Brutus, the teaching of the Stoics; but the practical men, the men of arts and arms and business, if they adhered to any school of thought at all, were almost all, like Cæsar himself and his associates generally, addicted to the easy precepts and still laxer morality of Epicurus. This philosophy was noted for its utter denial of Providence and, for all practical objects, of divinity altogether. None of these rival systems, whatever degrees of right sense and reason they might embrace respectively, could sanction any real belief in the still current mythology of the national worship, which was assailed and derided on all sides. Nevertheless, such was the pertinacious adherence of the Roman people to their ancient forms, especially where they had any connection with their national polity, that the outward ritual of their religion was still maintained, though a mere shadow of its former substance. Statesmen, indeed, had invented a formula for reconciling their actual unbelief with their outward profession. Varro had said, and the dictum was favourably accepted, that the ancient beliefs were to be upheld as a matter of public policy. Such, no doubt, was the principle on which Augustus, who was himself neither a believer nor a philosopher, but a politician only, proceeded, when he assumed the part of a restorer of the national religion. He touched, with great sagacity, a chord which vibrated to the heart of the people, who firmly believed that the destinies of the city were bound up with the due observance of the ancient rites, and statesmen looked on with decorous acquiescence at shows and ceremonies to which they attached no significance whatever.

The world "composes its countenance to the expression

assumed by the king." Such was the aphorism of the man of the world, and in this particular Augustus was a king indeed. The Romans rushed forward in the course he marked out for them. His word dictated the fashions of the day, not in sentiment only, but in many particulars of external conduct. He was anxious to restore the dignity of the Roman citizen, as one of the conquering race which ruled its subjects as much by the prestige of its character as by its arms, and he resented all relaxation from the strait-laced discipline of the ancients, even to the petty matters of their dress and deportment. He marked his sovereign displeasure at the degenerate Romans who indulged in the loose habiliments of Greece. "Are these," he exclaimed, in the language of Virgil, "the rulers of the world, the nation of the gown?" And in order to keep up the high distinction of Roman citizenship at a period when provincials from all sides were crowding into it, he reversed, in this single instance, the policy of Cæsar, and was very sparing in granting admission to the Roman franchise. He was, indeed, extremely careful in striking a balance between the tendency of the age to a general fusion of castes and privileges and the ancient spirit of exclusion, in which he thought the strength of the republic still really reposed. The policy of Augustus was one, on the whole, of cautious and moderate reaction. He made an effort to stay the process of disintegration, which he found so rife throughout the vital forces of the empire. The lawlessness of his own usurpation did indeed combine with the gross selfishness of his personal character to sap the moral principles of society, and render its ultimate dissolution inevitable; but he made a vigorous effort to stem the tide, and succeeded in giving the Roman world a period of rest in the downward path which it was generally pursuing.

Literature of the age. The character of the period, however, as an epoch of rest for reflection and self-control, was chiefly marked in the literature, which, more than anything else, has contributed to give it the name of the Augustan Age. The religious sentiment which has been described, resting as it did upon a deep sympathy with historical antiquity,

Virgil. coloured by a bold and vigorous imagination, is reflected in the poetry of Virgil, and more particularly in the spirit of his great epic, the *Æneid.* No doubt, both depth and tenderness of feeling may be traced even in the eclogues of the same master, however slight for the most part their subjects, and however imitative their treatment. The *Georgics* present us with more serious and dignified characteristics, and though these pieces are directed mainly to the practical treatment of practical operations, they admit of high moral as well as religious colouring. They recall the Roman reader to the moral foundations of the national character, its honest simplicity, its love of nature, its devotion to labour, its conviction that industry is the appointed path to virtue and to honour. But this moral feeling is elevated by a sense of the divine within man and around him. The Roman husbandman, the breed of heroes, is never suffered to forget that there is a God and a Providence, or that the favour of the divine power has always fallen upon the industrious and the virtuous. "Thus it is that Etruria of old, and Rome in later times, waxed illustrious and mighty; thus that the city on the seven hills became the fairest object of creation." The *Georgics* are undoubtedly animated throughout with a religious sentiment, and bespeak the high religious purpose of their author. But in the *Æneid* this religious sentiment and purpose are both still more distinctly proclaimed to us. The great epic of Virgil, the national epic of the Roman people, glorifies the divine Providence which founded Rome in the beginning, and carried her through all her triumphs to the consummation of her greatness in the era of Augustus. It begins with the divine Æneas, and it leads us on to the divine Cæsar. The greatness and the weakness of the hero of the poem equally tend to this one end, the illustration of the Providence which has educed strength out of weakness, and overruled everything to the glory of the Roman people. The moral to be deduced from the story of Æneas is too plain for any Roman to mistake. The divinity which protects Rome is the Lord of heaven and earth and all that is therein. There is no God or Lord like unto Him. Blessed are the Romans who have this Lord for their God. The majesty of the Roman empire, now at the crowning summit of its progress, is the immediate efflux of this sovereign power, and the one is for ever bound up with the other. If such was the doctrine sung by Virgil, surely none could be more grateful to Augustus, the sovereign ruler of an empire so guided and protected.

The names of Virgil and Horace are familiarly united Horace in every review of the age of Augustus; yet no two men can stand more in contrast one with the other in their personal character, in the scope of their writings, and in the influences they respectively exercised upon their contemporaries. Horace, as is well known, had been a republican in his youth; he had espoused the cause of Brutus and Cassius, and, while yet a student in the schools at Athens, had obtained a commission in their army. He fought in person in the battle of Philippi, and, as he tells us himself, threw away his shield in his rapid flight from the swords of the Cæsarians. From that time he abjured the losing cause, and obtained, perhaps without seeking it, the advice of the minister Mæcenas, by whom he was taken into favour and introduced to Augustus himself. However agreeable might be his temper and manners, it is not likely that the politic usurper would distinguish a mere upstart with admission to his society without at least tacitly exacting some return. The character of this poet's compositions, both in his lyrics and his satires and epistles, seems pretty clearly to betray the inspiration of the emperor and his astute associates. The most animated and imaginative of his pieces are almost invariably employed in sounding the praises of the Cæsar and his family. When he descends from his highest flights of poetry, he finds congenial matter for his muse in delicate flattery of Mæcenas and other magnates of the court. But it will be observed that he seldom, if ever, addresses the haughty nobles of Rome except in a strain of prudential advice, soothing their pride, but lowering their ambition, and directing them to seek contentment and happiness not in objects of public interest, but in the tranquil enjoyment of ease, which he dignifies with the name of philosophy. The poetry of Horace is full of pleasing sentiments, but it contains perhaps no single strain of generous and ennobling enthusiasm. Such feelings it was the policy of Augustus to discourage, and the policy of Augustus is faithfully represented in the utterances of his courtly flatterer. But there was another task imposed upon him, and it is to this that his satires and epistles are more commonly directed, namely, to put out of countenance the offensive self-assertion of the "new men" of the empire, the men whom the fortunes of the civil war had suddenly raised from their native obscurity, and enriched or ennobled, notwithstanding the barrenness of their origin and the vulgarity of their breeding. Augustus wanted, no doubt, to tame the aspiring spirits of his genuine nobles, but he shrank from driving them to desperation by swamping them with an inundation of base-born inferiors, perhaps their own former clients and freedmen. It was part of Horace's office, as a gentleman usher at court, to discountenance all such undue pretensions, and shut the door with consummate urbanity upon the most disagreeable or the most importunate of the courtiers. He

possessed in perfection both the delicate irony and the graceful amenity which are essential to the performance of a task so critical. Doubtless Horace, in his own peculiar line, exercised as great an influence in Roman society as Virgil. The laughing philosopher was no less a power among his contemporaries than the religious devotee. Each of them, in his several way, performed an immense service to the government under which he enjoyed favour and reward; nor can we deny that, considering how necessary the government of Augustus was to the bleeding commonwealth, each in his several way did an invaluable service to his country.

Nor, though we may admit that irony and persiflage were Horace's *forte*, should we do him justice if we supposed that he had no feelings of genuine tenderness and earnestness. Even Horace had his instinctive sense of religious duty, which peeps out occasionally from under the robe of his pretended philosophy, and shows that he recognised a principle of duty, and felt ill at ease in the consciousness of his own deficiencies. We may recognise in many of his later compositions his growing dissatisfaction with the worldly views of life which he had been wont to recommend, and some efforts at the attainment of higher sources of satisfaction. Both Virgil and Horace were cut off in middle life, but both, we imagine, had already entered into the cloud, and were painfully conscious that the commonwealth they loved had fallen into its decline, and that their own attempts to invigorate or to soothe it were little likely to prove availing. If Virgil deserves our admiration, Horace too is not unworthy of our sympathy; and it is well that we can part in such good temper from the two most perfect artists of the Roman, or perhaps of the ancient, world altogether.

Of Ovid, the third great poet of the Augustan Age, we can hardly think or speak so favourably. Ovid, too, was a genuine representative of his epoch, which occupied, however, the latter part of the career of Augustus, when the character of the age had begun to show manifest signs of deterioration. In the character of this poet, which may be abundantly gathered from his numerous works, there appears no religious feeling and no moral purpose. Nevertheless, his writings reflect, in some important particulars, the social tendencies of the epoch, and afford valuable illustrations of the genius of the Augustan Age. To the historian and archæologist the *Fasti* presents a store of interesting information; but in this poetical account of the Roman calendar the writer undoubtedly proposed to meet a social want of the time. The work is in fact a *rationale* of the divine offices, and expounds to the nation the "seasons and the reasons (*tempora cum causis*)" of the religious services which the emperor recommended to their pious attention. Minute and manifold as were the memorials of their past history, or of their accredited mythology, which the *cult* of the Roman temples enshrined, we can imagine how much they must have faded away from the recollection of the people generally during the century of confusion from which they had just emerged, and how even the priests and flamens of the national divinities must have stood in need of a learned interpreter of the rites which they mechanically performed. The *Fasti* is remarkable as a speaking witness to the fact of the ceremonial revival of the Augustan Age.

The generally immoral tendency of a great part of Ovid's poetry is well known; and it speaks all the worse for the character of the age that the writer could declare, and probably not without justice, that his personal conduct was purer than the sentiments with which he sought to please the public. The deterioration of sentiment between Virgil and Ovid is marked in the tone with which they speak in the higher flights of their respective poetry. The writer of the *Æneid* fully maintains the pure standard of thought and expression which he received as a tradition from Homer, and which had been respected by the epic poets generally; but Ovid, in his *Metamorphoses*, an heroic, if not an epic, composition, allows himself to descend far below this exalted level, and is not only licentious in his language, but seems to choose, and of set purpose, the most licentious of the stories which his varied subject offers. Again, though Horace adopts the lighter tone and looser phraseology of the lyric poets of Greece, there is at least nothing meretricious in his style; he was not a corrupter of youth himself, nor were the models such which he proposed for adaptation. But Ovid descends to the imitation of a more wanton kind of poetry. He, too, seeks his models for the most part from among the Greeks, but they are the Greeks of a more degenerate age—the Greeks of the court of Alexandria, who pandered to the vicious tastes of a corrupt and degraded society. But, imitator as he doubtless was, Ovid had a strong personal individuality, and all his poetry is marked with the genuine sentiment of his age and country. Perhaps we trace more of the real man in his *Tristia* and *Ex Ponto*, in which he is thrown entirely on his own resources, though in the depth of his affliction and the decline of his powers, than in the abler and more interesting works in which he owed we know not how much to the Greeks before him.

We have, besides these, the remains of other poets, such as Tibullus and Propertius, who also hold up the mirror to their times, and assist us in scanning its character on all sides. But it will be well to pass them over in this brief sketch, and bring our review of the literature of the Augustan Age to a close with a notice of the great historian Livy. The consummate excellence in form and style of the work to which we refer bears witness to the intellectual accomplishments of the epoch. No doubt the Romans did much at a later period to improve their method of teaching, and to extend their acquaintance with the highest models of literary excellence. An age succeeded in which Rome was formed into an academy, like that of Athens or Alexandria, when all the arts and sciences of the time were taught or practised under the direct instruction of approved professors. Great were the merits of the historical literature of Rome at a later age, and illustrious are some of the men who distinguished themselves in its exercise. But, on the whole, a reasonable criticism will award to Livy the palm of merit at least in the two particulars just specified,—a palm which he may well contest even with the masters of the art in Greece. The form of Livy's history partakes in exquisite proportion of the descriptive, the narrative, and the dramatic; it is replete with personal characteristics, which bring us into direct acquaintance with the individuals of whom it treats; it abounds, moreover, in matter of antiquarian interest, which we who read it at a distance of nineteen centuries feel to be specially valuable, and which did not fail to attract the sympathy even of the writer's own contemporaries. The Romans in the time of Augustus were just beginning to be keenly self-conscious. They felt that they had attained to such a position in the world's history as no people before them had acquired. They were led by all the traditions of their youth to attribute their splendid success to the examples of national virtue paraded before them. They were sensible of the deep debt they owed to their ancestors, and they wanted to know who their ancestors were; they wanted to trace the features of their own character in the lineaments of the great men who had gone before them. Of these ancient heroes of the commonwealth they had hitherto imbibed a faint and vague conception from songs and poems and family or national traditions. The legends connected with their ritual and their laws and

Livy.

institutions assumed the existence of those heroes, and the reality of the deeds imputed to them; but the men and their deeds were for the most part wrapped in obscurity, or presented under dubious colours. The voice of Livy's contemporaries muttered around him that of all their compatriots he should be held most in honour among them, who should bring these traditions of the past into the light of day, and make them pass among a generation, willing so to accept them, as genuine and accredited history. The history of Livy was the true product of the age, inasmuch as it answered to the call of the age. It presented Roman history to the Romans much as Shakespeare's dramas presented English history to the English; the history in both cases was just what the people wished to believe, and from thenceforth they so accepted and believed it.

As regards the style of Livy's composition, it is enough to say that it is generally regarded as the most perfect specimen of the Latin prose writing that we possess, and we may be pretty confident that if anything better had been written, posterity would not have suffered it to perish. It holds the middle place between the oratorical exuberance of Cicero and the philosophic sententiousness of Tacitus. While sentence follows sentence throughout in logical sequence, so that the thread of meaning and argument is never lost under a mass of verbiage, yet we are beguiled in our lengthened study by the repeated recurrence of passages of highly-imaginative colouring; we feel that if the historian sometimes deviates into poetry, he never misleads us with a show of empty rhetoric. The Roman people, as represented by Livy, retained the genuine strength and bluntness of their character. The teaching of their Greek instructors had had as yet little effect in seducing them into the conceits and affectations of the more frivolous people they had conquered. The history of Livy remains the noblest monument of the *Romanus honos*, the national dignity, which his countrymen so proudly contrasted with the *Graia licentia*, which was gradually enervating and degrading them. The spirit of the Augustan Age is set forth, perhaps at its best and brightest, in the illustrious history of Livy.

It is probable that Livy, who had been a republican in his heart, lived for the most part the retired life of a student, though he is said to have been employed in the education of some of the princes of the imperial family. He reflects the character of the earlier generation, among whom he was born, rather than of the later, in which he died, at an advanced age, in the fourth year of Tiberius. All the great poets above mentioned met an early death about the middle of the principate of Augustus, except Ovid, who survived to the eighth year of his successor. Accordingly, it is in Ovid, as might be expected, that we trace the first marks of degeneracy from the high standard of the Augustan literature—the Golden Age of Latin composition. The decline of Rome, both in intellect and morals, was becoming rapidly apparent. The splendid promise of the Augustan Age was quickly exhausted. The spirit of freedom evaporated under the influences of the time, and the spurious appearances which the emperor kept up had no power to impart real vigour to the national constitution. Just in the same manner it is abundantly clear that the fame of the age of Louis XIV. in France is founded on the excellence of the men who were actually born and bred in an earlier epoch and under a healthier *régime*. Neither the age of Augustus nor that of Louis produced the men who have rendered it illustrious. But the decline of Rome was becoming marked before the death of Augustus in other respects also. Although internal dissensions had been appeased, and private ambition quelled, the external relations of the empire were insecure, and caused vivid apprehensions. The frontiers of the Rhine and Danube were constantly harassed by the indomitable spirit of the barbarians beyond them. On the Danube the Roman arms seem to have been crowned with a sufficient measure of success, but on the Rhine the great disaster of Varus, and the loss of three legions, left a deep impression of gloom upon the feelings of the age. Augustus himself suffered a succession of disappointments in the premature death of his nearest kindred, and in the loss of his trustiest advisers. Though he maintained to the last an outward serenity almost touching, he appears to have been painfully conscious of the substantial failure of the great pacification he had accomplished, and to have augured nothing but evil from the character of the stepson, to whom, at the last moment, he was content to leave his inheritance. A general foreboding of evil was creeping over the minds of his people. The age of Augustus, which lasted nearly fifty years, was indeed a long day even in the life of a nation, but its sun was manifestly hastening to its setting, and the night was coming, slowly, gradually, but surely. (C. M.)

AUGUSTUS II. (also, and more accurately, designated FREDERICK AUGUSTUS I.), Elector of Saxony and King of Poland, second son of John George III. of Saxony, was born at Dresden, 12th May 1670. His personal beauty was remarkable, and from his great physical strength he received the surname of The Strong, by which he is commonly distinguished. He was very carefully educated, and spent several years travelling in Europe, visiting most of the courts, and taking part in some campaigns against the French. In 1694 he succeeded his elder brother as elector of Saxony, and shortly after, having entered into alliance with Austria, was appointed to the chief command of the imperial forces against the Turks. In 1697, after having suffered a defeat at Olasch, he resigned this office, and proceeding to Vienna, entered into negotiations with regard to the throne of Poland, left vacant by the death of John Sobieski in 1696. As a preliminary step in his candidature, Augustus renounced the Protestant faith, and proclaimed himself a Catholic. Among his rivals the most formidable was the French prince of Conti. Both expended enormous sums in buying over the Polish nobles, and both claimed to be elected at the general diet. Conti, however, was not on the spot, and Augustus, marching into Poland with his Saxon forces, gained possession of the kingdom. Scarcely was he settled on the throne, when he entered into alliance with Russia and Denmark against the young king of Sweden, and with his Saxon troops (for the Poles would not unite with him) invaded Livonia. In the campaigns which followed (1700–1704), he was completely worsted by the extraordinary military genius of his opponent, the celebrated Charles XII. of Sweden; he was driven from Poland, and Stanislaus Leszczinski was crowned in his place. The Swedes, following up their victories, invaded Saxony, and in 1706, at Altranstädt, Augustus was compelled to make peace, to repay the expenses of the Swedish army, to acknowledge Stanislaus as king of Poland, and to congratulate him on his accession. After these reverses he spent some time as a volunteer in the Netherlands, but the defeat of Charles at Pultowa (1709) again raised his hopes. He at once declared the Altranstädt treaty null and void, and having received promises of assistance from Russia, entered Poland, drove out Stanislaus, and was a second time proclaimed king. During the following years he continued to carry on the war with Sweden, while at the same time his kingdom was distracted by the jealousy with which the Poles regarded the Saxon troops, who were compelled to leave Poland in 1717. In 1718 Charles XII. was killed at Fredericshall, and from that time the reign of Augustus was marked by no important event. His court became celebrated as the

most extravagant and luxurious in Europe, and he himself as the most dissolute and magnificent of princes. His lavish expenditure, though it enriched his capital with treasures of art, impoverished both Poland and Saxony, and laid the foundations for the future misfortunes of those countries. He died, 1st February 1733, from mortification of an old wound. Of his numerous natural children, the most famous was the distinguished general, Maurice of Saxony.

AUGUSTUS III., or FREDERICK AUGUSTUS II., Elector of Saxony and King of Poland, only legitimate son of Augustus the Strong, was born at Dresden, 7th October 1696. He was brought up in the Protestant faith, but in 1712, while on his travels, he entered the Church of Rome, though his change of opinion was not publicly known till 1717. In 1733 he succeeded his father as elector of Saxony, and put forward claims to the kingdom of Poland. The Polish nobles, however, had become dissatisfied with foreign rule, and endeavoured to reinstate Stanislaus Leszczinski, whose daughter was married to Louis XV. of France. Russia and Austria, probably bribed, but certainly dreading French influence in Poland, supported Augustus, who was elected, though in an informal manner, and by their aid established himself in the kingdom. On the death of Charles of Austria in 1740, Saxony at first joined the league against Maria Theresa, but jealousy of the Prussian successes in the first campaign caused Augustus to unite with the empress when war broke out a second time in 1744. His forces were completely defeated by Frederick, and Saxony was overrun and pillaged by the Prussian troops. Eleven years later Augustus joined the alliance against Frederick, which gave rise to the Seven Years' War. He was again unfortunate; the whole Saxon army was surrounded and compelled to surrender at Pirna in 1756, and during the remainder of the war Saxony and Poland were the seats of operations, and suffered severely. Augustus died 5th October 1763, surviving only by a few months the peace of Hubertsburg. During his reign considerable additions were made to the collections of art treasures formed by his father, and Dresden began to be celebrated throughout Europe for its china and pictures.

AUK, a name common to several species of sea-fowl belonging, with one exception, to the family *Alcidæ*. Of these, special interest attaches to the Great Auk, or Garefowl (*Alca impennis*), from the circumstance that there is no authentic record of its having been taken, or even seen alive, for more than a quarter of a century. In the autumn of 1821 Dr Fleming, while on a cruise through the Hebrides, observed and described one which had been taken alive in the sea off St Kilda and put on board the yacht. With a rope attached to one of its legs, this specimen was occasionally allowed to disport itself in its native element, where it astonished every one by the rapidity with which it swam under water. On one of these occasions it got loose from its bonds, and was soon beyond reach of pursuit. Another specimen had been observed a few years before off Papa Westra, one of the Orkney Islands, but in spite of the exertions of the crew of a six-oared boat, continued for several hours, the auk could not be overtaken. This specimen, however, was afterwards secured, and is now in the British Museum. The Great Auk measures about three feet in length, has a large bill, but wings so small as to be totally useless for flying, serving, however, as powerful swimming organs. It is said to have laid a single egg on the bare rock,—usually, from the inability of the bird to rise on wing to the higher cliffs, close to the water edge. Its food, according to Fabricius, consisted of the lump-sucker and other fishes of a similar size. From the earliest existing accounts, the Great Auk does not appear to have ever been more than an occasional visitant to the British Isles, and then chiefly to the sea around St Kilda and the Orkneys, while Iceland, the Faroes, and the islets about Newfoundland, appear to have been its proper home. The probability that this bird is now totally extinct gives special value to the remains of it now existing. These, according to Professor Newton, are as follows:—71 or 72 skins, 9 skeletons, 38 or 41 detached bones of different birds, and 65 eggs. The other Auks are the Puffin, the Razorbill, and the Little Auk, all widely distributed along the northern-temperate and Arctic coasts.

AULIC COUNCIL (from the Latin *aula*, a hall, in German, *Reichshofrath*), one of the two supreme courts of the old Germanic empire, the other being the imperial chamber (*Reichskammergericht*). It was called into existence in 1501 by the Emperor Maximilian, and was by him intended to counterbalance the influence of the imperial chamber, which he had been compelled to form by the states six years before. The Aulic Council had in many respects equal power with the chamber; from its decisions there was no appeal, and under its special jurisdiction were included the consideration of the imperial reserved rights, fees, and privileges, the settlement of disputes as to precedence among the several states, and the arrangement of matters relating to the Italian possessions of the empire. All questions of law could be submitted either to this council or to the chamber. The members were at first appointed by the emperor, at whose death the court dissolved, and new appointments were made by his successor. The power of the council increased under several of the emperors; it was formally recognised as coequal with the imperial chamber; and after the peace of Westphalia its organisation was altered so as to meet the requirements of the time. It then and afterwards consisted of a president, vice-president, and eighteen councillors, all selected and paid by the emperor, and of a vice-chancellor, whose appointment rested with the electorate of Mainz. Six members were Protestants, and the votes of these six, when unanimous, could not be overturned by any majority of the others. The councillors were divided into two parties—the first consisting of the counts and barons, the second of the men of learning, who possessed equal rights with the nobles, but were more highly paid. At the dissolution of the old Germanic imperial system in 1806, the Aulic Council in its former signification came to an end, though an Austrian court bearing the same title still continued to sit in Vienna.

AULIS, a town in Bœotia, supposed to have been situated on a rocky peninsula between two bays, about three miles S. of Chalcis. During the Trojan war it was the rendezvous of the Greek fleet, and has obtained celebrity as the scene of the sacrifice of Iphigenia. Pausanias states that in his day there was still to be seen here the temple of Artemis ascribed to Agamemnon.

AUMALE, formerly ALBEMARLE, from the Latin *Alba Marla*, a town of France, in the department of Seine Inférieure, on the banks of the Bresle, 35 miles N.E. of Rouen. Grain and hemp are cultivated in the neighbourhood; cloth is manufactured; and the town has a trade in wool and cattle. Population, 2229. Aumale was erected by William the Conqueror into a countship, which was afterwards held in succession by the houses of Castile, Dammartin, Harcourt, and Lorraine; and in 1547 it was raised to the rank of a dukedom in favour of Francis of Lorraine. It afterwards passed to the house of Savoy, from whom it was purchased in 1675 by Louis XIV., who conferred it as an appanage on one of his natural sons. In 1769 it came into possession of the house of Orleans. The earl of Albemarle, in the British peerage, derives his title from Aumale.

AUNGERVYLE, RICHARD, commonly known by the name of *Richard de Bury*, was born in 1281, at Bury St

Edmund's in Suffolk, and educated at the university of Oxford. He entered the order of Benedictine monks, but was shortly afterwards appointed tutor to the prince of Wales. On the accession of his pupil to the throne as Edward III., he was promoted to various offices of dignity, and was finally made bishop of Durham, as well as lord high chancellor and treasurer of England. He was several times engaged in embassies on the Continent, and became acquainted with many of the most eminent men of the time, particularly with the poet Petrarch. A portion of his correspondence with the latter has been preserved. At Oxford he founded a library for the use of the students, which he furnished with the best collection of books then in England, and appointed five keepers, to whom he granted yearly salaries. He died at his manor of Auckland, 24th April 1345, and was buried in the cathedral church of Durham. His works are—(1.) *Philobiblon*, containing directions for the management of his library at Oxford, and an elaborate eulogy of learning, written in very bad Latin,—first printed at Cologne 1473, then at Spires, 1483, and finally at Oxford, 1599; (2.) *Epistolæ Familiarium*, some of which are addressed to Petrarch; (3.) *Orationes ad Principes*, mentioned by Bale and Pits.

AURAY, a small town of France, situated on the slope of a hill near the mouth of the river of the same name, in the department of Morbihan, 10 miles W. of Vannes. Its port is greatly frequented by coasting vessels; and it carries on a considerable industry in stocking-weaving, silk-spinning, tanning, shipbuilding, &c. The principal buildings are the church of St Esprit (13th century), which is now transformed into a college, the church of St Gildas, the town-house (17th century), and the Chartreuse, which marks the site of the battle of 1364, in which Charles of Blois was defeated by John de Montfort. In the neighbourhood is the church of Sainte Anne d'Auray, one of the principal places of pilgrimage in Brittany. Population, 4542. (See Palliser's *Brittany and its Byeways*, 1869.)

AURELIANUS, CÆLIUS, a celebrated Latin physician, born probably at Sicca in Numidia, but regarding whose life scarcely anything is known. The very date at which he flourished is quite uncertain. In his books he refers frequently to Soranus, and does not mention Galen, from which it has been inferred that he lived at a period intermediate between these two writers, *i.e.*, during the 2d century A.D. But if the writings under his name are, as seems at least probable, translations or paraphrases from Soranus, the absence of any reference to Galen can easily be understood. Again, Galen does not mention Aurelianus, though he notices many minor physicians; from which fact, together with the corrupt Latin style of his extant works, it has been supposed by several authorities that the more correct date is the 5th century A.D. The writings of Aurelianus, which are composed from the point of view of the methodical school, and show considerable practical skill in the diagnosis of ordinary and even of exceptional diseases, consist of the following:—(1.) A treatise, in three books, on acute diseases (*Acutarum* or *Celerum Passionum*), Paris, 1533 and 1826. (2.) A treatise, in five books, on chronic diseases (*Tardarum* or *Chronicarum Passionum*), Basle, 1529. Both these treatises were published together in 1566, and frequently since. (3.) Fragments of a comprehensive treatise on medical science in the form of a dialogue (*Medicinales Responsiones*), referred to in the preface to the work on acute diseases, have been discovered and published by Val. Rose in his *Anecdota Græca et Græco-Latina*, vol. ii. 1871.

AURELIUS ANTONINUS, MARCUS, the noblest of pagans, the crown and flower of Stoicism, was born at Rome 121 A.D., the date of his birth being variously stated as the 21st and the 26th April. His original name was Marcus Annius Verus. His father, Annius Verus, died while he was prætor; his mother, who survived her husband, was Domitia Calvilla or Lucilla. By both his parents he was of noble blood, his mother being a lady of consular rank, and his father claiming descent from Numa Pompilius. Marcus was an infant when his father died, and was thereupon adopted by his grandfather. The latter spared no pains upon his education, and the moral training which he received, both from his grandfather and from his mother, and to which he alludes in the most grateful and graceful terms in his *Meditations*, must have been all but perfect. The noble qualities of the child attracted the attention of the Emperor Hadrian, who, playing upon the name Verus, said that it should be changed to Verissimus. When Marcus reached the age of seventeen, Hadrian adopted, as his successor, Titus Antoninus Pius (who had married Annia Galeria Faustina, the sister of Annius Verus, and was consequently the uncle of Marcus), on condition that he in turn adopted both his nephew and Lucius Ceionius Commodus, the son of Ælius Cæsar, whom Hadrian, being childless, had originally intended as his successor, but who had died before him. It is generally believed that, had Marcus been old enough, Hadrian would have adopted him directly.

After the death of Hadrian, and the accession of Antoninus Pius to the throne, it became at once apparent that a distinguished future was in store for Marcus. He had been, at the age of fifteen, betrothed to the sister of Commodus; the engagement was broken off by the new emperor, and he was instead betrothed to Faustina, the daughter of the latter. In 139 A.D. the title of Cæsar was conferred upon him, and he dropped the name of Verus. The full name he then bore was Marcus Ælius Aurelius Antoninus, Ælius coming from Hadrian's family, and Aurelius being the original name of Antoninus Pius. He is generally known as Marcus Aurelius or Marcus Aurelius Antoninus. In 140 A.D. he was made consul, and entered fully upon public life.

The education of Aurelius in his youth was so minute, and has been so detailed by himself, that it ought not to be passed over without notice. Professor Long says, with perfect truth, apparently, of the trainers and the trained, "Such a body of teachers, distinguished by their acquirements and their character, will hardly be collected again, and as to the pupil we have not had one like him since." We have already alluded to the care bestowed upon him in youth by his mother and grandfather; a better guardian than that thoroughly good man and prudent ruler, Antoninus Pius, could not be conceived. Marcus himself says, "To the gods I am indebted for having good grandfathers, good parents, a good sister, good teachers, good associates, good kinsmen and friends, nearly everything good." He never attended any of the Roman public schools, and this he makes a matter for self-congratulation. He was trained by tutors, in whom, particularly in Rusticus, he appears to have been very fortunate, and to whom he showed gratitude when he reached the throne by raising them to the highest dignities of the state. Like most of the young Romans of the day, he began his studies with rhetoric and poetry, his teachers being Herodes Atticus and M. Cornelius Fronto. But at the early age of eleven, he entered upon another course of study, in which he may be said to have continued more or less till the end of his life. He became acquainted with Diognetus the Stoic, was fascinated by the philosophy he taught, assumed the dress of his sect, and ultimately abandoned rhetoric and poetry for philosophy and law, having among his teachers of the one Sextus of Chæronea, and of the other L. Volusianus Marcianus, a distinguished jurist. He went thoroughly and heartily into the practice as well as the

theory of Stoicism, and lived so abstemious and laborious a life, that he injured his health. It was from his Stoical teachers that he learned so many admirable lessons,—to work hard, to deny himself, to avoid listening to slander, to endure misfortunes, never to deviate from his purpose, to be grave without affectation, delicate in correcting others, "not frequently to say to any one, nor to write in a letter, that I have no leisure," nor continually to excuse the neglect of ordinary duties by alleging urgent occupations. Through all his Stoical training, Aurelius preserved the natural sweetness of his nature, so that he emerged from it the most lovable as well as the saintliest of Pagans.

Antoninus Pius reigned from 138 to 161 A.D., and the concord between him and his destined heir was so complete, that it is recorded that during these twenty-three years Marcus never slept oftener than twice away from the house of Pius. It is generally believed that Aurelius married Faustina in 146, at all events a daughter was born to him in 147. The two noblest of imperial Romans were associated both in the administration of the state and in the simple country occupations and amusements of the sea-side villa of Lorium, the birthplace of Pius, to which he loved to retire from the pomp and the wretched intrigues of Rome.

Antoninus Pius died of fever 161 A.D., at his villa of Lorium, at the age of seventy-five. As his end approached, he summoned his friends and the leading men of Rome to his bedside, and recommended to them Marcus, who was then forty years of age, as his successor, without mentioning the name of Commodus, his other adopted son, commonly called Lucius Verus. It is believed that the senate agreed with what appeared to be the wishes of the dying emperor, and urged Aurelius to take the sole administration of the empire into his hands. But at the very commencement of his reign, Marcus showed the magnanimity of his nature by admitting Verus as his partner in the empire, giving him the tribunician and proconsular powers, and the titles Cæsar and Augustus. This was the first time that Rome had two emperors as colleagues. Verus proved to be a weak, self-indulgent man; but he had a high respect for his adoptive brother, and deferred uniformly to his judgment. Although apparently ill-assorted, they lived in peace; and Verus married Lucilla, the daughter of Aurelius. In the first year of his reign Faustina gave birth to twins, one of whom survived to become the infamous Emperor Commodus.

The early part of the reign of Aurelius was clouded by various national misfortunes: an inundation of the Tiber swept away a large part of Rome, destroying fields, drowning cattle, and ultimately causing a famine; then came earthquakes, fires, and plagues of insects; and finally, the unruly and warlike Parthians resumed hostilities, and under their king, Vologeses, defeated a Roman army and devastated Syria. Verus, originally a man of considerable physical courage and even mental ability, went to oppose the Parthians, but, having escaped from the control of his colleague in the purple, he gave himself up entirely to sensual excesses, and the Roman cause in Armenia would have been lost, and the empire itself, perhaps, imperilled, had Verus not had under him able generals, the chief of whom was Avidius Cassius. By them the Roman prestige was vindicated, and the Parthian war brought to a conclusion in 165, the two emperors having a triumph for their victory in the year following. Verus and his army brought with them from the East a terrible pestilence, which spread through the whole empire, and added greatly to the horrors of the time. The people of Rome seem to have been completely unnerved by the universal distress, and to have thought that the last days of the empire had come. Nor were their fears without cause. The Parthians had at the best been beaten, not subdued, the Britons threatened revolt, while signs appeared that various tribes beyond the Alps intended to break into Italy. Indeed, the bulk of the reign of Aurelius was spent in efforts to ward off from the empire the attacks of the barbarians. To allay the terrors of the Romans, he went himself to the wars with Verus, his headquarters being Carnuntum on the Danube. Ultimately, the Marcomanni, the fiercest of the tribes that inhabited the country between Illyria and the sources of the Danube, sued for peace in 168. The following year Verus died, having been, it is said, cut off by the pestilence which he had brought from Syria, although in that wicked age there were not wanting gossips malignant enough to say even of Marcus that he hastened his brother's death by poison.

Aurelius was thenceforth undisputed master of the Roman empire, during one of the most troubled periods of its history. Mr Farrar, in his *Seekers after God*, thus admirably describes the manner in which he discharged his multifarious duties:—"He regarded himself as being, in fact, the servant of all. It was his duty, like that of the bull in the herd, or the ram among the flocks, to confront every peril in his own person, to be foremost in all the hardships of war, and most deeply immersed in all the toils of peace. The registry of the citizens, the suppression of litigation, the elevation of public morals, the care of minors, the retrenchment of public expenses, the limitation of gladiatorial games and shows, the care of roads, the restoration of senatorial privileges, the appointment of none but worthy magistrates, even the regulation of street traffic, these and numberless other duties so completely absorbed his attention, that, in spite of indifferent health, they often kept him at severe labour from early morning till long after midnight. His position, indeed, often necessitated his presence at games and shows, but on these occasions he occupied himself either in reading, in being read to, or in writing notes. He was one of those who held that nothing should be done hastily, and that few crimes were worse than the waste of time."

Peace was not long allowed the emperor. The year after the death of his partner, two of the German tribes, the Quadi and the Marcomanni, renewed hostilities with Rome, and, for three years, Aurelius resided almost constantly at Carnuntum, that he might effectually watch them. In the end, the Marcomanni were driven out of Pannonia, and were almost destroyed in their retreat across the Danube. In 174 Aurelius gained a decisive victory over the Quadi, to which a superstitious interest is attached, and which is commemorated by one of the sculptures on the Column of Antonine. The story is that the Roman army had been entangled in a defile, from which they were unable to extricate themselves, while at the same time they suffered intensely from thirst. In this extremity a sudden storm gave them abundance of rain, while the hail and thunder which accompanied the rain confounded their enemies, and enabled the Romans to gain an easy and complete victory. This triumph was universally considered at the time, and for long afterwards, to have been a miracle, and bore the title of "The Miracle of the Thundering Legion." The Gentile writers of the period ascribed the victory to their gods, while the Christians attributed it to the prayers of their brethren in a legion to which, they affirmed, the emperor then gave the name of Thundering. Dacier, however, and others who adhere to the Christian view of the miracle, admit that the appellation of Thundering or Lightning (κεραυνοβόλος, or κεραυνοφόρος) was not given to the legion because the Quadi were struck with lightning, but because there was a figure of lightning on their shields. It has also been

virtually proved that it had the title even in the reign of Augustus.

Even after this Aurelius was not allowed to rest. From Rome, to which he had returned, he marched to Germany to carry on the war against the tribes which harassed the empire. There the alarming news reached him that Avidius Cassius, the brave and experienced commander of the Roman troops in Asia, had revolted and proclaimed himself emperor. But the rebellion did not last long. Cassius had only enjoyed his self-conferred honour for three months, when he was assassinated, and his head was brought to Marcus. With characteristic magnanimity, Marcus did not thank the assassins for what they had done; on the contrary, he begged the senate to pardon all the family of Cassius, and to allow his life to be the only one forfeited on account of the civil war. This was agreed to, and it must be considered as a proof of the wisdom of Aurelius's clemency, that he had little or no trouble in pacifying the provinces which had been the scene of rebellion. He treated them all with forbearance, and it is said that when he arrived in Syria, and the correspondence of Cassius was brought him, he burnt it without reading it. During this journey of pacification his wife Faustina, who had borne him eleven children, died. The gossiping historians of the time, particularly Dion Cassius and Capitolinus, charge Faustina with the most shameless infidelity to her husband, who is even blamed for not paying heed to her crimes. But none of these stories rest on evidence which can fairly be considered trustworthy; while, on the other hand, there can be no doubt whatever that Aurelius loved his wife tenderly, and trusted her implicitly while she lived, and mourned deeply for her loss. It would seem that Aurelius, after the death of Faustina and the pacification of Syria, proceeded, on his return to Italy, through Athens, and was initiated in the Eleusinian mysteries, the reason assigned for his doing so being, that it was his custom to conform to the established rites of any country in which he happened to find himself. Along with his son Commodus he entered Rome in 176, and obtained a triumph for victories in Germany. In 177 occurred that persecution of Christians, the share of Aurelius in which has caused great difference of opinion, and during which Attalus and others were put to death. Meanwhile the war on the German frontier continued, and the hostile tribes were defeated as on former occasions. In this campaign Aurelius led his own forces; and, probably on that account, he was attacked by some infectious disease, which ultimately cut him off, after a short illness, according to one account, in his camp at Sirmium (Mitrovitz) on the Save, in Lower Pannonia, and, according to another, at Vindobona (Vienna), on the 17th March 180 A.D., in the fifty-ninth year of his age. His ashes (according to some authorities, his body) were taken to Rome, and he was deified. Those who could afford the cost obtained his statue or bust, and, for a long time, statues of him held a place among the Penates of the Romans. Commodus, who was with his father when he died, erected to his memory the Antonine Column (now in the Piazza Colonna at Rome), round the shaft of which are sculptures in relief commemorating the miracle of the Thundering Legion and the various victories of Aurelius over the Quadi and the Marcomanni.

The one blemish in the life of Aurelius is his hostility to Christianity, which is the more remarkable that his morality comes nearer than any other heathen system to that of the New Testament. Attempts have been made to show that he was not responsible for the atrocities with which his reign is credited, but the evidence of Justin, of Athenagoras, of Apollinaris, and, above all, of Melito, bishop of Sardis, and of the Church of Smyrna, is overwhelmingly to the effect that not only were there severe persecutions of Christians, in which men like Polycarp and Justin perished, but that the foundation of these persecutions was certain rescripts or constitutions issued by Aurelius as supplementary to the milder decrees of his predecessors Hadrian and Antoninus Pius. In explanation, however, if not in extenuation, of the attitude of Aurelius towards Christianity, several circumstances should be taken into consideration. In the first place, it is evident that he knew little of the Christians, and absolutely nothing of Christian ethics. In his *Meditations* he makes only one reference (xi. 3) to the adherents of the new creed, and that of the most contemptuous character, showing that he confounded them all with certain fanatics of their number, whom even Clemens of Alexandria compares, on account of their thirst for martyrdom, to the Indian gymnosophists. How far this ignorance was culpable it is impossible at so remote a date to say. Further, it should be noted, in regard to the rescripts upon which the persecutions were founded, that, although they were in the name of the emperor, they may not have proceeded directly from him. There is no evidence that he was an active persecutor, except a passage in Orosius to the effect that there were persecutions of the Christians in Asia and Gallia "under the orders of Marcus;" and it should not be kept out of consideration that he was to some extent a constitutional monarch, and had to pay deference both to the *consulta* of the senate and the precedents of previous emperors. At the time there was a great popular outcry against the Christians on social and political, even more than on religious, grounds; and Aurelius may have been as much at the mercy of intriguers or fanatics when he gave his sanction to the butcheries of Christians in Asia Minor, as William III. was at the mercy of Stair and Breadalbane, the real authors of the massacre of Glencoe. Finally, it should be borne in mind that, in the reign of Aurelius, the Christians had assumed a much bolder attitude than they had hitherto done. Not only had they caused first interest and then alarm by the rapid increase of their numbers, but, not content with a bare toleration in the empire, they declared war against all heathen rites, and, at least indirectly, against the Government which permitted them to exist. In the eyes of Aurelius they were atheists and foes of that social order which he considered it the first of a citizen's duties to maintain, and it is quite possible that, although the most amiable of men and of rulers, he may have conceived it to be his duty to sanction measures for the extermination of such wretches. Still his action at the time must be considered, as John Stuart Mill puts it, as "one of the most tragical facts in all history."

The book which contains the philosophy of Aurelius is known by the title of his *Reflections*, or his *Meditations*, although that is not the name which he gave to it himself, and of the genuineness of the authorship no doubts are now entertained. It is believed that the emperor also wrote an autobiography, which has perished with other treasures of antiquity. The *Meditations* were written, it is evident, as occasion offered,—in the midst of public business, and even on the eve of battles on which the fate of the empire depended,—hence their fragmentary appearance, but hence also much of their practical value and even of their charm. It is believed by many critics that they were intended for the guidance in life of Aurelius's son, Commodus. If so, history records how lamentably they failed in accomplishing their immediate effect, for Commodus proved one of the greatest sensualists, buffoons, and tyrants that disgraced even the Roman purple. But they have been considered as one of the most precious of the legacies of antiquity,—as, in fact, the best of non-inspired reflections on practical morality. They have been recognised as among the most effectual stimuli to strugglers

in life, of whatever class and in whatever position, in the field of speculation as in that of action. The *Meditations* of Marcus Aurelius were, with Machiavelli's *Art of War*, the daily study of Captain John Smith, the real founder of the United States. They are placed by Mr Mill in his posthumous essay on the *Utility of Religion* as almost equal in ethical elevation to the Sermon on the Mount.

Aurelius early embraced, and throughout life adhered to, the Stoical philosophy, probably because he considered it as the sternest and most solid system to oppose to the corruption of his time. But, as Tenneman says, he imparted to it "a character of gentleness and benevolence, by making it subordinate to a love of mankind, allied to religion." In the *Meditations* it is difficult to discover anything like a systematic philosophy, which, indeed, means, as he used the word, tranquillity, or a serene habit of mind. From the manner, however, in which he seeks to distinguish between matter (ὕλη) and cause or reason (αἰτία, λόγος), and from the Carlylean earnestness with which he advises men to examine all the impressions on their minds (φαντασίαι), it may be inferred that he held the view of Anaxagoras—that God and matter exist independently, but that God governs matter. There can be no doubt that Aurelius believed in a deity, although Schultz is probably right in maintaining that all his theology amounts to this,—the soul of man is most intimately united to his body, and together they make one animal which we call man; and so the deity is most intimately united to the world or the material universe, and together they form one whole. We find in the *Meditations* no speculations on the absolute nature of the deity, and no clear expressions of opinion as to a future state. We may also observe here that, like Epictetus, he is by no means so decided on the subject of suicide as the older Stoics. Aurelius is, above all things, a practical moralist. The goal in life to be aimed at, according to him, is not happiness, but tranquillity, or equanimity. This condition of mind can be attained only by "living conformably to nature," that is to say, one's whole nature, and as a means to that, man must cultivate the four chief virtues, each of which has its distinct sphere—wisdom, or the knowledge of good and evil; justice, or the giving to every man his due; fortitude, or the enduring of labour and pain; and temperance, or moderation in all things. It is no "fugitive and cloistered virtue" that Aurelius seeks to encourage; on the contrary, man must lead the "life of the social animal," must "live as on a mountain;" and "he is an abscess on the universe who withdraws and separates himself from the reason of our common nature through being displeased with the things which happen." While the prime principle in man is the social, "the next in order is not to yield to the persuasions of the body, when they are not conformable to the rational principle which must govern." This "divinity within a man," this "legislating faculty" (τὸ ἡγεμονικόν) which, looked at from one point of view, is conscience, and from another is reason, must be implicitly obeyed. He who thus obeys it will attain tranquillity of mind; nothing can irritate him, for everything is according to nature, and death itself "is such as generation is, a mystery of nature, a composition out of the same elements, and a decomposition into the same, and altogether not a thing of which any man should be ashamed, for it is not contrary to the nature of a reasonable animal, and not contrary to the reason of our constitution."

The morality of Marcus Aurelius cannot be said to have been new when it was given to the world, far less can it be said to be systematic. Compared, indeed, with elaborate treatises on ethics, the *Meditations* of Marcus Aurelius are as tonic medicine to succulent food. The charm of his morality lies in its exquisite accent and its infinite tenderness. Where can the connoisseur in morals find anything finer than such sentences as this?—"The pride which is proud of its want of pride is the most intolerable of all;" or where can a more delicate rebuke to the Pharisaism which lurks in the breast of every man be obtained than this?—"One man, when he has done a service to another, is ready to set it down to his account as a favour conferred. Another is not ready to do this, but still, in his own mind, he thinks of the man as his debtor, and he knows what he has done. A third in a manner does not even know what he has done, but he is like a vine which has produced grapes, and seeks for nothing more after it has once produced its proper fruit. So a man when he has done a good act, does not call out for others to come and see, but he goes on to another act as a vine goes on to produce again the grapes in season." But above all, what gives the sentences of Marcus Aurelius their enduring value and fascination, what renders them superior to the utterances of other moralists of the same school, such as Epictetus and Seneca, is that they are the gospel of his life. His practice was in accordance with his precepts, or rather his precepts are simply the records of his practice. To the saintliness of the cloister he added the wisdom of the man of the world; constant in misfortune, not elated by prosperity, never "carrying things to the sweating point;" preserving, in a time of universal corruption, unreality, and self-indulgence, a nature, sweet, pure, self-denying, unaffected, Marcus Aurelius has given to the world one of the finest examples of the possibilities of humanity.

The *Meditations* of Marcus Aurelius have been translated into English, German, French, Spanish, and Italian. The two chief English translations are those of Jeremy Collier (1702) and of George Long; the last may be considered final. The text most commonly used is the Greek one edited by J. M. Schultz (republished by Tauchnitz in 1821). Many books have been written on the life and times of Aurelius, and the essays on his *Meditations* are innumerable. One of the best estimates of him is contained in Mr F. W. Farrar's *Seekers after God*, 1868. A scholarly work issued in 1874 by M. Gaston Boissier, entitled *La Religion Romaine d'Auguste aux Antonines*, gives, perhaps, the most interesting existing account of the state of society under the Antonines.

AUREOLA, Aureole, the radiance or luminous cloud which, in paintings of sacred personages, is represented as surrounding the whole figure. In the earliest periods of Christian art this splendour was confined to the figures of the persons of the Godhead, but it was afterwards extended to the Virgin Mary and to several of the saints. The aureola, when enveloping the whole body, is generally oval or elliptical in form, but is occasionally circular or quatrefoil. When it is merely a luminous disk round the head, it is called specifically a *nimbus*, while the combination of nimbus and aureole is called a *glory*. The strict distinction between nimbus and aureole is not commonly maintained, and the latter term is most frequently used to denote the radiance round the heads of saints, angels, or persons of the Godhead.

AURICH, a town of Prussia, in the province of Hanover, situated on the Trecktief canal. It is regularly built; possesses a castle, which was formerly the residence of the prince of East Friesland, a lyceum, and four libraries; and carries on the manufacture of leather, paper, pottery, and tobacco. The famous meeting-place of the East Frieslanders, *Upstaalsboom*, is in the neighbourhood. Population, 4264.

AURIFABER (the Latinised form of the name Goldschmidt), Joannes, a Lutheran divine, celebrated as the

friend of Luther and as one of the editors of his works, was born in 1519 in the county of Mansfeldt, or, more probably, in the town of Weimar. After completing his education at the university of Wittenberg, where he heard the lectures of Luther, he became tutor to Count Mansfeldt, and in the war of 1544-5 accompanied the army as field-preacher. For some months afterwards he resided with Luther as his *famulus* or private secretary, and was present at his death in 1546. In the following year he spent six months in prison along with John Frederick, elector of Saxony, who had been captured by the emperor, Charles V. He held for some years the office of court-preacher at Weimar, but, owing to theological disputes, was compelled to resign this office in 1561. In 1566 he was appointed to the Lutheran church at Erfurt, which post he held, though not without serious differences with his fellow-clergymen, till his death in 1575. Besides taking a share in the first collected or Jena edition of Luther's works, Aurifaber sought out and published at Eisleben in 1564-5 several writings not included in that edition. He also published Luther's *Letters* (1556, 1565), and *Table Talk* (1566).

AURIFABER, JOANNES, a Lutheran divine, born at Breslau in 1517. He was educated at Wittenberg, and was there specially attracted to Melanchthon, with whom he ever afterwards remained on terms of close friendship. After graduating in 1538 he spent twelve years as *docent* at the university, and having then received his doctorate of divinity, was appointed professor of divinity and pastor of the church of St Nicholas at Rostock. He distinguished himself by his prudence and conciliatory disposition, took a leading part in the composition of the regulations for the Mecklenburg church, and was successful in allaying some religious disputes in the town of Lübeck. The Grand-duke Albert of Prussia, who was very desirous of healing the differences in the Prussian Church caused by the discussion of Osiander's doctrines, was attracted by Aurifaber, invited him to Königsberg in 1553, and in the following year appointed him to the professorship of divinity in that university, and to the presidency of the Samland diocese. Aurifaber, however, found it impossible to conciliate all parties, and in 1565 returned to Breslau, where, for the three remaining years of his life, he discharged the joint offices of pastor in the church of St Elizabeth and director of the Lutheran Church and schools. He died 19th October 1568.

AURILLAC, the capital of the department of Cantal, France, situated on the right bank of the Jourdanne, which is here crossed by a handsome bridge. It contains tribunals of primary instance and commerce, a communal college, societies of agriculture, arts, and commerce, a public library, and a museum. Most of the town is of comparatively modern construction, its more ancient buildings having suffered severely in the religious wars of the 16th century. Of highest claims to antiquity are portions of the castle of St Etienne, the church of St Géraud, and a Benedictine abbey, which is regarded by many as the original nucleus round which Aurillac gathered. There is a statue of Sylvester II., who was a native of the town, and was educated in the abbey, which soon afterwards became one of the most famous schools of France. The manufactures consist of tapestry, lace, cutlery, paper, leather, &c., and a considerable number of horses are bred. Population in 1872, 11,098.

AURORA, the Roman personification of the dawn of day, corresponding to the Greek goddess Eos.

AURORA POLARIS

AURORA POLARIS, AURORA BOREALIS and AUSTRALIS, POLAR LIGHT, NORTHERN LIGHTS, or STREAMERS, an electrical meteor, appearing most frequently in high latitudes, in the form of luminous clouds, arches, and rays, of which the latter sometimes meet at a point near the zenith, and form what is called a *boreal crown*. The arches are sometimes single; sometimes several concentric ones are seen, and they are usually nearly stationary, or move slowly southward. They cross the magnetic meridian at right angles, and, therefore, in England, have their centres nearly N.N.W. The rays rise perpendicularly from the arches, but are sometimes seen detached, or when the arch is below the horizon. They are parallel to the dipping needle, or, in other words, to the curves of magnetic force; and the boreal crown, at which they appear to meet, is merely an effect of perspective. This point is in England about 70° in altitude, and nearly S.S.E. of the zenith. The rays are seldom stationary, but appear and disappear suddenly, shooting with great velocity up to the zenith, and moving slowly eastward or westward, but most commonly the latter. They sometimes cover the whole sky, and frequently have a strong tremulous motion from end to end. This tremulous motion is sometimes seen also in the arches when near the zenith; and Benjamin V. Marsh mentions a case in which the matter of the arch had the appearance of a rapid torrent flowing from east to west. A rare form of aurora is that in which the rays appear to hang from the sky like fringes or the folds of a mantle. The ordinary colour of the aurora is a pale greenish-yellow, but crimson, violet, and steel-colour are not uncommon. Crimson auroras have often been imagined by the superstitious to be omens of war, pestilence, and famine; and lively imaginations have seen in their motions—

> "Fierce fiery warriors fight upon the clouds
> In ranks, and squadrons, and right form of war."

They were called by the ancients *chasmata*, *bolides*, and *trabes*, according to their forms and colours. In Shetland, where they are very frequent, and in the north of Scotland, they are known as the "*merry dancers*" (perhaps the ancient *capræ saltantes*); while, from a curious passage in Sirr's *Ceylon and the Cingalese*, vol. ii. p. 117, it seems that the aurora, or something like it, is occasionally visible in Ceylon, and that the natives call it the *Buddha lights*. Mr Jansen says, however, that the great aurora of 4th February 1872, which was seen at Bombay, was not visible in Ceylon. In many parts of Ireland a scarlet aurora is supposed to be a shower of blood, and under this name is not unfrequently mentioned in the old annals, always in connection with some battle or the murder of a great chief. The earliest mentioned was in 688, in the *Annals of Cloon-mac-noise*, after a battle between Leinster and Munster, in which Foylcher O'Moyloyer was slain. It was observed at Edessa in 502, and in Syria in 1097, 1098, and 1117.

The only thing resembling a distinct history of this phenomenon is that which has been given by Dr Halley, in the *Philosophical Transactions*, No. 347. The first account he gives, taken from a book entitled *A Description of Meteors*, by W. F., D.D., reprinted at London in 1654, describes the appearance of what is called by him *burning spears*, which were seen at London on the 30th January 1560. The next appearance, according to the testimony of Stow, was on the 7th October 1564. In 1574 also, according to Camden and Stow, an aurora borealis was observed two nights successively, viz., on the 14th and 15th of November, having much the same appearances as that described by Dr Halley in 1716. Again, an aurora History

was twice seen in Brabant, in the year 1575, viz., on the 13th of February and 28th of September. Both appearances were described by Cornelius Gemm, professor of medicine at Louvain, who compares them to spears, fortified cities, and armies fighting in the air. Michael Mæstlin, tutor to Kepler, states that at Backnang in Würtemberg these phenomena, which he styles *chasmata*, were seen by himself no less than seven times in 1580. In 1581 they again appeared in great splendour in April and September, and in a less degree in some other months of the same year. In September 1621, a similar phenomenon was observed all over France, and described by Gassendi, who gave it the name of *aurora borealis;* yet neither this, nor any similar appearance posterior to 1574, is described by English writers till the year 1707. From 1621 to 1707, indeed, there is no mention made of an aurora borealis having been seen at all; and, considering the number of astronomers who during that period were continually scanning the heavens, it might almost be supposed that nothing of the kind really made its appearance until after an interval of eighty-six years. A small one was seen in November 1707; and during that and the following year the same appearances were repeated five times. The next on record is that mentioned by Dr Halley in March 1716, which from its brilliancy attracted universal attention, and was considered by the common people as marking the introduction of a foreign race of princes. Since that time these meteors have been much more frequent, and most of our readers must have seen the brilliant displays within the last few years which have been visible over the whole of Europe.

One singular phenomenon which seems to be connected with the aurora is that of a dark bank of cloud below the arches, and usually just above the northern horizon. Although this appears decidedly darker than the uncovered portion of the sky, it is of so thin a character that stars can be seen through it, as well as through the auroral arches and rays, with but little diminution of brightness. It is, however, quite possible that this cloud is only the somewhat misty open sky near the horizon, which appears darker by contrast with the bright arch above it.

Sounds from aurora.

It has been repeatedly affirmed that cracking, hissing, or whizzing sounds have been heard proceeding from the polar lights, and the natives of high latitudes are almost unanimous in alleging that this is sometimes the case. Scoresby, Richardson, Franklin, Parry, Hood, and later observers seem to have listened in vain for such noises, and it seems that in the intense cold of the Arctic night the contraction of the ice, or its cleavage under the pressure of approaching tempests, produces sounds exactly such as are described. Still, mere negative evidence must be received with caution, and it is very possible that in high latitudes such sounds may occasionally be heard, since the electric discharge seems to originate near the poles. The aurora, too, seems to vary greatly in height, and in lower latitudes is usually at such an altitude that audible sounds from it are quite impossible. Musschenbroeck says that the Greenland fishers in his time assured him that they had frequently heard noises proceeding from the aurora borealis, and his testimony is confirmed by that of many others. There is no *a priori* improbability of such sounds being occasionally heard, since a somewhat similar phenomenon accompanies the brush discharge of the electric machine, to which the aurora bears considerable resemblance.

ylight rora.

Numerous observers (*Nature*, iv. 27, 47) have attested the occasional visibility of aurora by daylight. In the *Transactions of the Royal Irish Academy*, 1788, Dr H. Ussher notices that aurora makes the stars "flutter" very much in the telescope, and states that, having noticed this effect strongly one day at 11 A.M., he examined the sky, and saw an auroral corona with rays to the horizon. J. Glaisher, Franklin, and others, have also observed the phenomenon. It is scarcely possible that a light so faint as not even to obscure the stars should be visible in sunlight, and such facts would seem to suggest that the auroral light is developed in cloud or mist of some sort, which may become visible by reflected light, as well as by its own. Franklin says, "Upon one occasion the aurora was seen immediately after sunset, while bright daylight was still remaining. A circumstance to which I attach some importance must not be omitted. Clouds have sometimes been observed during the day to assume the forms of aurora, and I am inclined to connect with these clouds the deviation of the needle, which was occasionally remarked at such times." The writer has seen aurora which could not be distinguished from clouds, till the further development of the display made their real nature evident. Dr Richardson thinks he has observed a polarity in the masses of cloud belonging to a certain kind of cirro-stratus approaching to cirrus, by which their long diameters, having all the same direction, were made to cross the magnetic meridian nearly at right angles. But the apparent convergence of such masses of cloud towards the opposite points of the horizon, which have been so frequently noticed by meteorologists, is an optical deception, produced when they are situated in a plane parallel to that on which the observer stands. These circumstances, says Dr Richardson, are here noticed, because if it shall hereafter be proved that the aurora depends upon the existence of certain clouds, its apparent polarity may, perhaps, with more propriety, be ascribed to the clouds themselves which emit the light; or, in other words, the clouds may assume their peculiar arrangement through the operation of one cause (magnetism, for example), while the emission of light may be produced by another, namely, a change in their internal constitution, perhaps connected with a motion of the electrical fluid. D. Low (*Nat.*, iv. 121) states that he has witnessed as complete a display of auroral motions in the cirrus cloud as he ever beheld in a midnight sky. He thinks that all clouds are subject to magnetic or diamagnetic polarisation, and states that when the lines converge towards the magnetic pole, fine weather follows; when they are at right angles to this position, wet and stormy. The aurora appears in these latitudes usually to occur at a height much greater than that of ordinary clouds. Dr Richardson's observations (Franklin and Richardson's *Journey to the Shores of the Polar Sea*) seem to show, however, that, in the Arctic regions, the aurora is occasionally seated in a region of the atmosphere below a kind of cloud which is known to possess no great altitude, namely, that modification of cirro-stratus which, descending low in the atmosphere, produces a hazy sheet of cloud over head, or a fogbank in the horizon. Indeed, Dr Richardson is inclined to infer that the aurora borealis is constantly accompanied by, or immediately precedes, the formation of one or other of the forms of cirro-stratus. On the 13th of November and 18th December 1826, at Fort Enterprise, its connection with a cloud intermediate between cirrus and cirro-stratus is mentioned; but the most vivid coruscations of the aurora were observed when there were only a few thin attenuated shoots of cirro-stratus floating in the air, or when that cloud was so rare that its existence was only known by the production of a halo round the moon. The natives of the Arctic regions of North America pretend to foretell wind by the rapidity of the motions of the aurora; and they say that when it spreads over the sky in a uniform sheet of light, it is followed by fine weather, and that the changes thus indicated are more or less speedy, according as the appearance of the meteor is early or late in the evening,—an opinion not improbable, when it is recollected

Connection of aurora with clouds.

that certain kinds of cirro-stratus are also regarded by meteorologists as sure indications of rain and wind. Dr Richardson frequently observed the lower surface of nebulous masses illuminated by polar lights,—a fact illustrative of the comparatively low situation of these auroræ. Biot, also, in the island of Unst, observed many auroræ that could not be higher than the region of clouds. Sir John Franklin in like manner observed low auroræ. "The important fact," says he, "of the existence of the aurora at a less elevation than that of dense clouds was evinced on two or three occasions this night (13th February 1821, at Fort Enterprise), and particularly at 11 hours 50 min., when a brilliant mass of light, variegated with the prismatic colours, passed between a uniform steady dense cloud and the earth, and in its progress completely concealed that portion of the cloud which the stream of light covered, until the coruscation had passed over it, when the cloud appeared as before." Captain Parry, as stated in his third voyage, observed auroræ near to the earth's surface. It is said that while Lieutenants Scherer and Ross and Captain Parry were admiring the extreme beauty of a polar light, they all simultaneously uttered an exclamation of surprise at seeing a bright ray of the aurora shoot suddenly downward from the general mass of light, and between them and the land, which was only 3000 yards distant. The ray or beam of the polar light thus passed within a distance of 3000 yards, or less than 2 miles, of them. Further, Mr Farquharson observed in Aberdeenshire an aurora borealis not more than 4000 feet above the level of the sea. Fitzroy believed that aurora in northern latitudes indicates and accompanies stormy weather at a distance, and that straining and cracking of the ice may cause the hissing and whizzing sounds.

M. Silbermann (*Comptes Rendus*, lxviii. p. 1051) notes facts which strongly confirm the connection of aurora with some form of cirrus cloud. He says (of the aurora of 15th April 1869),—"At 11 hours 16 min. the phenomenon disappeared in a singular fashion. It appeared as if the columns of the aurora were still visible, but the stars were hidden, and it soon became obvious that fan-like cirrus clouds, with their point of divergence in the north, had taken the place of the aurora. Between 1 and 2 in the morning these clouds had passed the zenith, and let fall a very fine rain. On stretching out the back of the hand one felt a pricking of cold, and now and then there were minute scintillations in the nearest strata of air, like a hail of tiny crystals of ice, which afterwards turned to a rain of larger and larger drops. At 4 o'clock in the morning the cirrus of the false aurora was still visible, but deformed towards the top, and presenting a flaky aspect. One interesting point is, that the cirrus never appeared to replace the aurora either from the right or the left, but to substitute itself for it, like the slow changes of a dioramic view." "I had previously observed a fall of small ice crystals on the 30th April 1865. At 6 P.M. Paris seemed enveloped in a cirrus of vertical fibres, recalling those of amianthus, and more or less wavy. It was a rain of little sparkling prisms. At the same time I heard a rustling or crepitation, and on extending my hand I felt a pricking sensation of cold, and distinguished the crystals which fell and melted immediately."

In a later memoir (*Ibid.*, p. 1120) he remarks that many storm-clouds throw out tufts of cirri from their tops, which extend over a great portion of the sky, and resolve themselves into a very fine and cold drizzle, which frequently degenerates into a warmer and more abundant rain. Usually the fibres are more or less sinuous, but in much rarer cases they become perfectly retilinear, and surround the cloud like a glory, and occasionally shine with a sort of phosphorescence. As an illustration he quotes his observations on the night of the 6th September 1865:—"A stormy cloud was observed about 11 P.M. in the N.N.W., and lightning was distinctly visible in the dark cumulous mass. Around this mass extended *glories* of a phosphorescent whiteness, which melted away into the darkness of the starry sky. Round the cloud was a single and uninterrupted corona, and outside this, two fainter coronæ broken by rifts which corresponded with each other. After the cloud had sunk below the horizon the *glories* were still visible. The light could not have been due to the moon or any foreign cause. The rays showed great mobility, and a sort of vibration intermediate between that of the aurora and the 'brush discharge' of the electric machine." He goes on to say that—

"Luminous clouds have been frequently observed. There are many examples in Gilbert's *Annals*, and we may recall also the observations of Becaria, Deluc, the Abbé Rozier, Nicholson, and Colla. Mists also are occasionally luminous, as, for instance, that observed by Dr Verdeil at Lausanne in 1753, and by Dr Robinson in Ireland."

A still more curious fact is mentioned by Sabine, who, during his magnetic survey, anchored some days at Loch Scavaig in Skye. This loch is surrounded by high and bare mountains, one of which was nearly always enveloped in a cloud, resulting from the vapours which almost constant west winds brought from the Atlantic. This cloud at nights was permanently self-luminous, and Sabine frequently saw rays similar to those of the aurora. He entirely repudiates the idea that the rays could be due to auroræ beyond the mountain, and is sure that these phenomena, whatever their nature, were produced in the cloud itself.

Silbermann asserts that auroræ are preceded by the same general phenomena as thunderstorms, and concludes that everything had happened as if the auroræ of 1859 and 1869 had been storm-clouds, which, instead of bursting in thunder, had been drawn into the upper parts of the atmosphere, and their vapour being crystallised in tiny prisms by the intense cold, the electricity had become luminous in flowing over these icy particles. This view is very strongly supported by the observation of Professor Piazzi Smyth that the monthly frequency of aurora varies inversely with that of thunderstorms. The following are his numbers of relative frequency, the means of all observations of the Scottish Meteorological Society prior to 1871:—

	Lightning.	Aurora.
January	24·0	29·7
February	14·4	42·5
March	7·0	35·0
April	15·4	27·5
May	37·4	4·8
June	48·0	0·0
July	53·2	0·5
August	38·4	12·6
September	22·4	36·6
October	20·8	49·4
November	15·0	32·4
December	15·0	28·8
Mean of whole year	24·0	20·1

It must, however, be remembered that the observed frequency of auroræ is much affected in Scotland by the continuous twilight during the summer months. If there be this connection between thunder-clouds and auroræ, it is not improbable that the "dark segment" is sometimes a real cloud or mist, situated at a height where the density of the air is too great for luminous discharge; and in several cases Silbermann has seen auroral rays rise from small clouds, which gradually melted entirely away, or left a small non-luminous nucleus when their electricity was discharged.

If, as would certainly be the case in a mist, any portion

Polarisation. of the auroral light is reflected, whether it be its own or derived from some other body, it should be polarised; but so far polariscope observations are deficient, and give no certain information. It is difficult to separate the proper polarisation of the aurora from the mere atmospheric polarisation of the sky. Mr Ranyard, who appears to have used a double-imaged prism and Savart during the great aurora of Feb. 4, 1872, and also to have made some observations on that of Nov. 11, 1871, did not detect polarisation. On the other hand, Prof. Stephen Alexander, in his report on his expedition to Labrador (App. 21, *U. S. Coast Survey Rep.*, 1860), found strong polarisation with a Savart, and, singularly enough, thought it strongest in the dark parts of the aurora. The observations were made in lat. about 60°, in the beginning of July, and near midnight, but he does not state whether there was twilight or any trace of air polarisation at the time, nor does he give the plane of polarisation.

Height. With regard to the height of auroræ, Sir W. R. Grove (*Nature*, vol. iii. p. 28) states that he saw an aurora some years ago at Chester in which the rays came between him and the houses; and Mr Ladd observed a similar case in which the lighthouse at Margate was visible through a ray. The evidence, however, appears strong that aurora is usually at a very great height. Dalton calculated the height of an auroral arch, which was seen as far north as Edinburgh, and as far south as Doncaster, and at most intermediate places, from its apparent altitude, as measured by its position in relation to the stars as seen from Kendal and Warrington, 83 miles apart. The resulting height was about 100 miles, and the position slightly south of Kendal. An observation at Jedburgh confirmed this, but some taken at Edinburgh placed it above Carlisle at a height of 150 miles. Dalton, however, considered the former reckoning the more trustworthy. Backhouse has made many calculations, and considers that the average height of auroræ ranges from 50 to 100 miles, and numerous other observers have calculated similar heights. All these observations, however, are liable to the objection, that different observers may really have seen different arches, of which, as has been remarked, there are often several concentric ones. It is not likely that this was really the case in most instances, but it has, no doubt, sometimes occurred, and may account for the heights of 500 to 1000 miles calculated by early observers. This difficulty is met by a method proposed by Prof. H. A. Newton (*Sill. Jour. of Sc.*, 2d ser. vol. xxxix. p. 286) for calculating the height by one observation of altitude and amplitude of an arch. It seems almost certain that the auroral arches are arcs of circles, of which the centre is the magnetic axis of the earth; or, at least, that they are nearly parallel to the earth's surface, and probably also to the narrow belt or ring surrounding the magnetic and astronomical poles, and passing through Faroe, the North Cape, and the north of Nova Zembla, which Loomis and Fritz have found to be the region of most frequent aurora. This being assumed, Prof. Newton finds that, d being the distance from the observer to the centre of curvature of the nearest part of this belt (which for England is situated about 75° N. lat., 50° W. long.), h the apparent altitude of the arch, $2a$ its amplitude on the horizon, x its height, R the earth's radius, and c the distance of the observer from the ends of the arch,—

$$\sin. \phi = \sin. d. \cos. a \operatorname{cosec.} (d+h) \quad . \quad (1),$$

$$\tan. c = 2 \sin. h \sin. \phi \sec. {}^2\phi \quad . \quad . \quad (2),$$

and

$$x = \mathrm{R} (\sec. c - 1) \quad . \quad . \quad . \quad . \quad (3).$$

He gives the heights of twenty-eight auroræ calculated by this method, ranging from 33 to 281 miles, with a mean of 130 miles. The method, of course, rests on the assumption that auroral arches are arcs of circles, but it is decidedly confirmatory both of this assumption and of the heights calculated by other methods. It cannot well be objected that such altitudes are beyond the limits of our atmosphere, since Prof. A. S. Herschel (*Nature*, vol. iv. 504) gives the height of twenty meteors varying from 40 to 118 miles, with an average of about 70 miles, and it is almost certain that these bodies are rendered incandescent by atmospheric friction. Assuming 0° C. as the temperature at the earth's surface, and the absolute zero, −273° C., as a minimum for the auroral region, the pressure would be about 0·2 millimetre (0·0078 inch) at a height of 100 kilometres (62 miles) above the earth's surface. This result, of course, assumes a good deal; but if correct, it implies a vacuum attainable with difficulty even with the Sprengel pump. The pressure may, however, be much greater in the path of the auroral beams, since, as Prof. A. S. Herschel suggests, electrical repulsion may carry air or other matter up to a great height. A similar effect is observed in the so-called vacuum tubes, in which the pressure becomes much greater in the narrow central part, while the discharge is passing. It is found that the apparent altitude of the auroral corona is always a little less than that indicated by the dipping needle, owing to the curvature of the lines of magnetic force, or, in other words, because its altitude corresponds with the inclination of the parallel of latitude over which it is actually situated; and Galle has suggested (*Pogg. Ann.*, cxlvi. 133), that from this divergence the height may be calculated, and, indeed, gives a series of heights so determined, which do not differ materially from Prof. Newton's. It is, however, doubtful if the position of these coronæ, and consequently the value of the small angle (not more than 4° or 5°), admit of sufficiently accurate determination for such a use.

Spectroscopic observations. Early observers, and especially Mr Canton, conjectured that the aurora was an electric discharge in the rarefied upper atmosphere, and the resemblance between it and the phenomena exhibited by discharges in an air-pump vacuum confirmed the idea. Recent spectroscopic observations have thrown some little doubt on this conclusion, or at least have shown that there is still a mystery left unexplained. When the light of any glowing gas is analysed by the prism, it is found to consist of a series of coloured lines and bands, of which the number and position is dependent on the nature of the gas, and which is called its spectrum. The light of the aurora gives a spectrum usually consisting of a single line in the greenish yellow, which does not coincide with a principal line of any known substance,—a spectrum totally different from those of the gases of the atmosphere. Besides this line there is occasionally visible a sharp line in the red, and several fainter and more refrangible bands. The following table includes most of the principal determinations of the auroral lines, which have hitherto been published:—

	WL.	Observer.	Remarks.	Mean WL.	Prob. Error.

Vogel remarks that the line at 5569, which is often the only one visible, as well as the faint band at 4667, become noticeably fainter when the red line is visible, while under the same circumstances that near 5189, as well as the red line, is very brilliant. This fact, which has also been noted by other observers, makes it almost certain that the auroral spectrum is not a simple one, but is derived either from two or more sources, or from the same source under very varying conditions. Angström says (*Nature*, x. 211)—

"It may be assumed that the spectrum of the aurora is composed of *two* different spectra, which, even although appearing sometimes simultaneously, have in all probability different origins. The one spectrum consists of the homogeneous yellow light which is so characteristic of the aurora, and which is found even in its weakest manifestation. The other spectrum consists of extremely feeble bands of light, which only in the stronger aurora attain such intensity as enables one to fix their position even approximately. As to the yellow line in the aurora, or the one-coloured spectrum, we are as little able now as when it was first observed to point out a corresponding line in any known spectrum. True, Piazzi Smyth (*Comptes Rendus*, lxxiv. 597) has asserted that it corresponds to one of the bands in the spectrum of hydrocarbons; but a more exact observation shows that the line falls into a group of shaded bands, which belong to the spectrum, but almost midway between the second and third. Herr Vogel has observed that this line corresponds to a band in the spectrum of rarefied air (*Pogg. Ann.*, cxlvi. 582). This is quite true, but in Angström's opinion is founded on a pure misconception. The spectrum of rarefied air has in the yellow-green part seven bands of nearly equal strength, and that the auroral line corresponds with the margin of one of these bands, which is not even the strongest, cannot be anything else than merely accidental."

Angström's own view is that this line is due to fluorescence or phosphorescence, and he remarks that "since fluorescence is produced by the ultra-violet rays, an electric discharge may easily be imagined, which though in itself of feeble light, may be rich in ultra-violet rays, and therefore in a condition to cause a sufficiently strong fluorescence. It is also known that oxygen is phosphorescent, as also several of its compounds." We are, however, just as ignorant of any body which would give such a light by phosphorescence or fluorescence as by ignition, and it seems more probable that the light may be due to chemical action. It is assumed by Angström that water vapour is necessarily absent in the higher atmosphere on account of the cold, but when we remember that its molecular weight is lighter than that of oxygen in the proportion of 9 to 16, it is not unlikely that it may attain great elevations under the very low tensions that prevail at such heights, and it is possible also that both it and other bodies may, by electric repulsion in the auroral beams, be carried up much above the level which they would attain by gravity. If, then, electric discharges take place between the small sensible particles of water or ice in the form of mist or cirrus, as Silbermann has shown to be likely, surface decomposition would ensue, and it is highly probable that the nascent gases would combine with emission of light. It has been almost proved in the case of hydrogen phosphide that the very characteristic spectrum produced by its combustion is due neither to the elements nor to the products of combustion, but to some peculiar action at the instant of combination, and it is quite possible that, under such circumstances as above described, water might also give an entirely fresh spectrum.

It is, perhaps, proper to mention that H. R. Procter found an apparent coincidence by often repeated direct comparison with a band frequently seen both in air and oxygen tubes, which he eventually succeeded in tracing with tolerable certainty to some form of hydrocarbon. The comparison spectroscopes were only of low dispersion, but on more accurate measurement of the carbon band it was found that, though more refrangible than the first band of citron acetylene (candle-flame), it was still less so than careful measurement assigns to the aurora. In addition, the band was shaded towards the violet, which is not the case with that of the aurora, though with feeble light it seemed like a line.

If, leaving the citron line, we pass on to the feeble spectrum towards the violet, we shall obtain more hopeful coincidences. Angström thinks that three of the bands correspond with the three brightest bands of the violet aurora of the negative pole in rarefied air, and has tried to reproduce the conditions of the aurora on a small scale. He says—

"Into a flask, the bottom of which is covered with a layer of phosphoric anhydride, the platinum wires are introduced, and the air is pumped out to a tension of only a few millimetres. If the inductive current of a Ruhmkorff coil be then sent through the flask, the whole flask will be filled, as it were, with the violet light, which otherwise proceeds only from the negative pole, and from both electrodes a spectrum is obtained consisting chiefly of shaded violet bands. If this spectrum be compared with that of the aurora, Angström thinks the agreement between the former and some of the best established bands of the latter is satisfactory.

Lines.		Wave Lengths.		
Of the aurora spectrum,	according to Barker,	431	470·5	...
	,, Vogel,	...	469·4	523·3
	,, Angström,	...	472	521
	,, Lemström,	426·2	469·4	523·5
	Mean,	428·6	470·3	522·6
Of the spectrum of the violet light,		427·2	470·7	522·7

In the neighbourhood of the line 469·4 Herr Vogel has, moreover, observed two weak light-bands, 466·3 and 462·9 (?). The spectrum of the violet has also two corresponding shaded bands, 465·4 and 460·1.

"Should the aurora be flamy, and shoot out like rays, there is good reason for assuming a disruptive discharge of electricity, and then there ought to appear the strongest line in the spectrum of the air, the green, whose wave-length is 500·3. Precisely this has actually been observed by Vogel, and has, moreover, been seen

by Angström and others. Finally, should the aurora be observed as it appears at a less height in the atmosphere, then are recognised both the hydrogen lines and also the strongest of the bands of the dark-banded air-spectrum. There are found also again nearly all the lines and light-bands of the weak aurora spectrum whose position has with any certainty been observed."

With regard to the red line, which is sometimes perfectly sharp and well defined, and occasionally, though very rarely, even as bright as the citron line, scarcely even a plausible theory has been hazarded. That it is not the C line of hydrogen is certain, as they have been directly compared, and are widely separated; and none of the air lines near its position are at all comparable to it in brightness. Vogel thinks it may "correspond with the first system of lines in the spectrum of nitrogen (6620 to 6213), and that probably only the bright part of this group of lines is visible on account of the extreme faintness of the aurora." This, however, cannot be the case, since the present writer has seen it both bright and sharp. Vogel points out that the line near 5189 closely corresponds to an oxygen line of that wave-length which is bright and constant under very different conditions of pressure and temperature. He states that the faint line near 5390 corresponds in like manner to a nitrogen line. He points out that, though the correspondences with the iron lines are very striking, but little weight can be laid on the fact, since many of the brightest lines of the iron spectrum do not appear. The following table gives the principal iron lines (Thalén) and the auroral ones; and it will be seen that the former are so abundant that coincidences could scarcely fail:—

Iron.	Brightness.	Aurora.	Iron.	Brightness.	Aurora.	Iron.	Brightness.	Aurora.
6490	6		5546	10		5167	8	5161
6399	10		5429	10		5139	8

5545	10		5192	8		4250	10	

Angström asserted some years since that he had detected the principal line of the aurora in the spectrum of the zodiacal light, but he appears to have been misled by a faint aurora, for more recent observers, and notably Prof. C. Piazzi Smyth, Mr Backhouse, and A. W. Wright (*Sill. Jour. of Sc.*, viii. 39), have found that the spectrum of the zodiacal light is continuous and quite analogous to that of twilight or faint starshine, and polariscope observations prove that it is mostly reflected. The very faint line positioned by Alvan Clark at 5320 has been said by Winlock to coincide with the principal coronal line 5322. The position of the auroral line is uncertain; and even if it were accurate, a single doubtful coincidence with a faint line is not the least proof of identity.

We have already remarked the manifest relation between the forms and position of auroræ and the earth's lines of magnetic force, and in addition to this have noted the disturbance of the magnetic needle during auroral displays. It is not, however, at such times only that the magnetic elements are subject to variation; the total force, declination, and inclination, all are constantly varying both regularly with the hours of the day and the seasons of the year, and irregularly at uncertain times. The irregular oscillations when violent are called magnetic storms, and it must be noted that auroral display never takes place except during such disturbances, although a large proportion of the most remarkable magnetic storms are unaccompanied by visible auroræ.

Franklin, who was one of the first observers of this relation (at Fort Enterprise, 64° 30′ N., 113° 10′ W.), says of the magnetic needle,—"The motion communicated to it was neither sudden nor vibratory. Sometimes it was simultaneous with the formation of arches, prolongation of beams, or certain other changes of form or action of the aurora. But generally the effect of these phenomena upon the needle was not visible immediately, but in about half an hour or an hour the needle had attained its maximum of deviation. From this its return to its former position was very gradual, seldom regaining it before the following morning, and frequently not until the afternoon, unless it was expedited by another arch of the aurora operating in a direction different from the former one."

"The arches of the aurora," he adds, "most commonly traverse the sky nearly at right angles to the magnetic meridian, but deviations from this direction, as has already been stated, were not rare; and I am inclined to consider that these different positions of the aurora have considerable influence on the direction of the needle. When an arch was nearly at right angles to the magnetic meridian, the motion of the needle was towards the west. This westward motion was still greater when one extremity of the arch bore 301°, or about 59° to the west of the magnetic north, that is, when the extremity of the arch approached from the west towards the magnetic north. A westerly motion also took place when the extremity of an arch was in the true north, or about 36° to the west of the magnetic north, but not in so great a degree as when its bearing was about 301°. A contrary effect was produced when the same end of an arch originated to the southward of the magnetic west, viz., when it bore from 245° to 234°, and of course when its opposite extremity approached nearer to the magnetic north. In these cases the motion of the needle was towards the east. In one case only a complete arch was formed in the magnetic meridian, in another the beam shot up from the magnetic north to the zenith; and in both these cases the needle moved towards the west.

"The needle was most disturbed on February 13th, P.M., at a time when the aurora was most distinctly seen passing between a stratum of clouds and the earth, or at least illuminating the face of the clouds opposed to the observer. This and several other appearances induced me to infer that the distance of the aurora from the earth varied on different nights, and produced a proportionate effect on the needle. When the light shone through a dense hazy atmosphere, when there was a halo round the moon, or when a small snow was falling, the disturbance was generally considerable; and on certain hazy, cloudy nights the needle frequently deviated in a considerable degree, although the aurora was not visible at the time. Our observations do not enable us to decide whether this ought to be attributed to an aurora concealed by a cloud or haze, or entirely to the state of the atmosphere. Similar deviations have been observed in the day-time, both in a clear and cloudy state of the sky, but more frequently in the latter case. An aurora sometimes approached the zenith without producing any change in the position of the needle, as was more generally the case; whilst at other times a considerable alteration took place although the beams or arches did not come near the zenith. The aurora was frequently seen without producing any perceptible effect on the needle. At such times its appearance was that of an arch, or an horizontal stream of dense yellowish light, with little or no internal motion. The disturbance in the needle was not always proportionate to the agitation of the aurora, but it was always greater when the quick motion and vivid light were observed to take place in a hazy atmosphere. In a few instances the motion of the needle was observed to commence at the instant a beam darted upwards from the horizon; and its former position was more quickly or slowly regained according to circumstances. If an arch was formed immediately afterwards, having its extremities placed on opposite sides of the magnetic north and south to the former one, the return of the needle was more speedy, and it generally went beyond the point from whence it first started."

Speaking of the aurora of May 13, 1869, M. Lamont of Munich says (*Comptes Rendus*, lxviii. 1201)—

"1. During 40 years I have only seen seven or eight auroræ at Munich, and this small number is insufficient for a study of the characters of the phenomenon.

"2. Auroræ, whether visible at Munich or not, are always accompanied by magnetic perturbations.

"3. In the perturbations of declination which I have observed for 28 years, I have been unable to recognise any general law.

"4. The perturbations of horizontal intensity commence in general by an increase of that force, and finish always by a diminution, which lasts for two or three days.

"5. In all perturbations there is a *constant relation* between changes of inclination and the simultaneous changes of horizontal intensity, such that an augmentation of intensity of $\frac{1}{1000}$ corresponds to a diminution of inclination of 8°·28 (for Munich).

"6. In telegraphic wires we cannot observe the existence of a constant terrestrial current, since the conductivity of the soil is infinitely greater than that of the telegraphic wire, and it is only *sudden changes* that manifest themselves. In consequence, during magnetic perturbations in the galvanometer of a telegraphic wire, we only see irregular deflections to right or left, succeeding each other at intervals of a few minutes.

"In 1850 and 1851 we made electrical observations from hour to hour, from 7 A.M. to 6 P.M., without being able to see any connection between the atmospheric electricity and the magnetic perturbations. Later I abandoned these observations, because the indications of the electrometers depended too much on local and accidental circumstances."

It should be noted here that the horizontal component of magnetic force varies with the inclination as well as with the intensity of the total force, and the ratio noted above is almost exactly that which would be produced by a change in the inclination alone; and it would appear as if the actual horizontal force, independent of the inclination, was subject to comparatively little variation. This is not improbable, since variations in the horizontal force could correspond only to electro-magnetic easterly or westerly currents, while changes in declination, inclination, and vertical force *might* correspond to currents from the magnetic north and south, which there is reason to believe are most frequent in auroral displays.

To give some idea of the extent of magnetic perturbations, we may mention that during the aurora of 13th May 1869, the declination at Greenwich varied 1° 25′, while the vertical force experienced four successive maxima, and the greatest oscillation amounted to 0·04 of its total mean value. The horizontal force at the same time only varied 0·014 of its mean value. During the aurora of the 15th April of the same year the declination at Stonyhurst varied 2° 23′ 14″ in nine minutes.

The electric currents produced at such times in telegraph wires, though transient, are often very powerful. Loomis (*Sill. Jour.*, vol. xxxii.) mentions cases where wires had been ignited, brilliant flashes produced, and combustible materials kindled by their discharge. It often happens that the ordinary signals are completely interrupted during their continuance.

Electrical character of aurora.

In addition to the resemblance between the auroral phenomena and those of electric discharges in rarefied gases which we have already mentioned, we have seen that auroral displays are accompanied by marked disturbances both in the direction and force of terrestrial magnetism. This fact is in itself almost proof of their electrical character, and, taken in conjunction with the strong "earth-currents" which are at such times produced in lines of telegraph, and with the manifest polarisation of the arches and rays with regard to the magnetic meridian, may be considered as conclusive that the aurora is some sort of electric discharge. There are still some points with regard to the origin of this electricity which are unexplained, and it is uncertain whether the magnetic disturbance causes the electrical phenomena, or *vice versa*. It has been shown by Prof. Plücker that when an electric discharge takes place through rarefied gas in the field of a magnet, it is concentrated in the magnetic curves, which are the only paths in which it can move without being disturbed by the magnet. This is well shown in De la Rive's well-known experiment, in which an electro-magnet is enclosed in an electric egg. As soon as the magnet is set in action, the discharge, which had before filled the egg, is concentrated into a defined band of light, which rotates steadily round the magnet,—the direction of its rotation being changed by reversal either of the current or of the polarity of the magnet. If we suppose that the aurora is an electric discharge passing from one magnetic pole to the other, and following the terrestrial magnetic curves, we shall find that the theory agrees with observed facts even in its lesser details. In these latitudes the magnetic curves are sensibly straight and parallel, and are inclined S.E. at an angle of about 70° from the perpendicular, and, by the well-known laws of perspective, will appear to converge towards this point, as, in fact, the auroral streamers do. The streamers should move from east to west, or from west to east, according as the discharge is from north to south, or *vice versa*, and, in fact, they are in constant motion. Professor Loomis (*Sill. Jour. of Sc.*, xxxiv. 45) gives a catalogue of forty-six cases of such movement, of which thirty-one were from E. to W. and only fifteen in the opposite direction; and as part of these apparent motions are due to a real motion from N. to S., he concludes that the actual motion of the streamers is from about N.N.E. to S.S.W. This would make the north pole the negative electrode, which is most likely usually the case. Prof. Loomis has shown that during auroral displays electrical currents traverse the earth's surface in the same general direction, though subject to great variation in intensity and even to reversal. Waves of magnetic disturbance are also propagated in the same direction (*ibid.*, xxxii. 318).

With regard to the arches it is evident that they are generally circles concentric to the magnetic pole, and it is very probable that they are analogous to the striæ often seen in discharges in rarefied gases. Gassiot, quoted by B. V. Marsh (*Sill. Jour.*, xxxi. 316, and *Roy. Soc. Proc.*, vol. x. Nos. 38 and 39), describes an experiment with his great Grove's battery of 400 cells, in which the exhausted receiver was placed between the poles of the large electro-magnet of the Royal Institution:—"On now exciting the magnet with a battery of ten cells, effulgent strata were drawn out from the positive pole, and passed along the under or upper surface of the receiver according to the direction of the current. On making the circuit of the magnet and breaking it immediately, the luminous strata rushed from the positive, and then retreated, cloud following cloud with a deliberate motion, and appearing as if swallowed up by the positive electrode." This, as Mr Marsh remarks, bears a very considerable resemblance to the conduct of the auroral arches, which almost invariably drift slowly southward; and we cannot do better than sum up his theory in his own words:—"The foregoing considerations seem to render it probable that the aurora is essentially an electric discharge between the magnetic poles of the earth leaving the immediate vicinity of the north magnetic pole in the form of clouds of electrified matter, which float southward through the atmosphere at a height of 40 miles or more from the earth, sometimes to a distance of more than 30° from the pole; that whilst they are thus moving forward, with a comparatively slow and steady motion, or sometimes even remaining almost stationary for a long time, bright streams of electricity are from time to time suddenly shot out from them in a nearly vertical direction, that is to say, in the magnetic curves corresponding to the points from which they originate; that these curves, ascending to a great height beyond the atmosphere, then bending more and more southward and downward until they finally reach corresponding points in the southern magnetic hemisphere, are the pathways by which the electric currents pass to their destination; and that for several hundred miles from the earth these curves are thus 'traced through space and illuminated with bright electric light;' and further, that the magnetism of the earth also causes these luminous currents and the electrified matter

composing the arch to revolve round the magnetic pole of the earth, giving them the motion from east to west, or from west to east, which the components of the arch are observed to have."

The principal difficulties and deficiencies of this hypothesis, which was first suggested by De la Rive, are that it makes no attempt to account for the origin of such an electrical discharge, and that it is difficult to understand how an electric current can traverse vast spaces of the almost perfect vacuum which must exist at the distance from the earth (many hundreds of miles) which is attained by the magnetic curves, since, in the best vacuums of our Sprengel pumps, discharge will not take place even across the interval of a few centimetres. It is not, however, certain that stellar space is an insulator, and it is possible, moreover, that the auroral currents do not follow the magnetic curves through their whole course, since electric discharge is always in the path of least resistance, and this is modified not only by the magnetic forces, but by atmospheric density, and it is possible that on attaining a certain height the current may proceed horizontally on a stratum of least resistance. It need create no surprise that the discharge is generally invisible in the intermediate zone of low latitudes, since this is well accounted for not only by the large surface over which it is spread at great heights, but because this part of its course is at right angles to the line of sight, while in higher latitudes we look at the streamers almost "end-on," and thus have before our eyes a very great depth of luminous gases. It is common enough, too, in discharges in rarefied gases to see the two poles surrounded by luminous auræ, while the intermediate space is almost or quite dark, or consists of luminous disks or striæ separated by dark spaces. It seems probable that this "glow" discharge in rarefied gases is really a sort of electrical convection, which is propagated comparatively slowly, and from particle to particle; and that the striæ are surfaces at which the difference of potential of the moving molecules is so great as to cause discharge between them, while in the intermediate dark spaces the electric force is carried mechanically and silently by the particles moving in regular currents under the repulsive and attractive forces of electrification. On this hypothesis the auroral discharge becomes comprehensible, since we have only to suppose that the electricity is carried mechanically, as it were, through the vacuous spaces, which, if they contain no matter to conduct electricity, can contain none to impede the motion of the molecules. It is, moreover, by no means certain that the bright rays indicate actual currents. They may simply consist of matter rendered luminous in the arches, and projected by magnetic or electrical repulsion in the curves of magnetic force, since Varley (*Roy. Soc. Proc.*, xix. 236) shows that when a glow discharge in a vacuum tube is brought within the field of a powerful magnet, the magnetic curves are illuminated beyond the electrodes between which the discharge is taking place as well as within the path of the current; and also that this illumination is caused by moving particles of matter, since it deflected a balanced plate of talc on which it was caused to impinge. It has also been shown that in electrical discharges in air at ordinary pressures, while the spark itself was unaffected by the magnet, it was surrounded by a luminous cloud or aura, which was drawn into the magnetic curves, and which might also be separated from the spark by blowing upon it. It is evident, therefore, that any mechanical force may separate the luminous particles from the electric discharge which produces them.

phi-
n.

With regard to the geographical distribution of aurora, Prof. Loomis (*Sill. Jour.*, xxxi.) has laid down a series of zones of equal auroral frequency, and in Petermann's *Mittheilungen* for October 1874, Prof. Fritz has given a chart embodying the results of his extensive researches on the same subject. He finds, like Prof. Loomis, that the frequency of auroral display does not continue to increase to the pole, but reaches a maximum in a zone which, for the northern hemisphere, passes through the Faroe Islands, reaches its most southern point, about 57°, nearly south of Greenland, passes over Nain on the Labrador coast, then tends northwards, across Hudson's Bay (60° N. lat.), and through great Bear Lake, and leaves the American continent slightly south of Point Barrow. It then skirts the northern coast of Asia, reaching its most northerly point, about 76° N., near Cape Taimyr, passing through the north of Nova Zembla, and skirting the N.W. coast of Norway. Not only are auroral displays less frequent in Iceland and Greenland than further south, but it is found that while south of this zone auroræ appear usually to the north of the observer, north of it they are generally to the south, and within it, north or south indifferently. South of this lie other zones approximately parallel to it, and of constantly diminishing frequency. That in which the average yearly number of auroræ is 100 passes through the Drontheim, the Orkneys, and the Hebrides, and reaches the American coast just north of Newfoundland. South of this the frequency diminishes rather rapidly. At Edinburgh the annual average is 30, at York 10, in Normandy 5; while at Gibraltar the average is about 1 in ten years.

These curves, which Prof. Fritz calls *isochasmen*, are nearly normal to the magnetic meridians, and bear a close relation to the curves of equal magnetic inclination, especially with those laid down by Hansteen in 1730, while they noticeably diverge in some places from those of Sabine of 1840. They also approximate to the isobaric curves of Schouw, and Prof. Fritz remarks that the curves of greater frequency tend towards the region of lowest atmospheric pressure. It is not unlikely that there may be such a connection, since Prof. Airy has showed a relation between barometric and magnetic disturbances.

It will be noticed that, eastward from England, the isochasmic curves tend rapidly northward, Archangel being only on the same auroral parallel as Newcastle. Prof. Fritz points out that they bear some relation to the limit of perpetual ice, tending most southward where, as in North America, the ice limit comes furthest south. He also endeavours to establish some connection between the periods of maximum of auroræ and those of the formation of ice, and considers ice as one of the most important local causes which influence their distribution. He quotes a curious fact mentioned by several Arctic voyagers, that aurora was most frequently seen when open water was in sight, and usually rather in the direction of the water than of the magnetic north. In this connection it may be well to remind our readers that the water of the Arctic regions is always warmer than the ice fields, and must cause upward currents of damp air. For the southern hemisphere there are not yet sufficient observations to make any determination of geographical distribution.

With regard to distribution in time Loomis and Fritz and Wolf have shown that there are periodical maxima about every ten or eleven years, and that these maxima coincide both with those of sun spots, and of magnetic disturbance. The following are Fritz and Wolf's dates of maxima:— Distribution in time.

Sun Spots.	Auroræ.	Sun Spots.	Auroræ.
1706	1707	1788	1788
1718	1721	1804	1804
1728	1728	1817	1816
1739	1738	1830	1830
1750	1749	1837	1839
1761	1760	1848	1848
1770	1769	1860	1860
1779	1779	1871	1872

The annexed chart from Prof. Loomis's paper (*Sill. Jour.*, April 1873) shows, in a very striking manner, the correspondence of auroræ, magnetic variation, and sun-spot area since 1776. It is not improbable that there may also be changes of longer period which our observations are yet insufficient to determine.

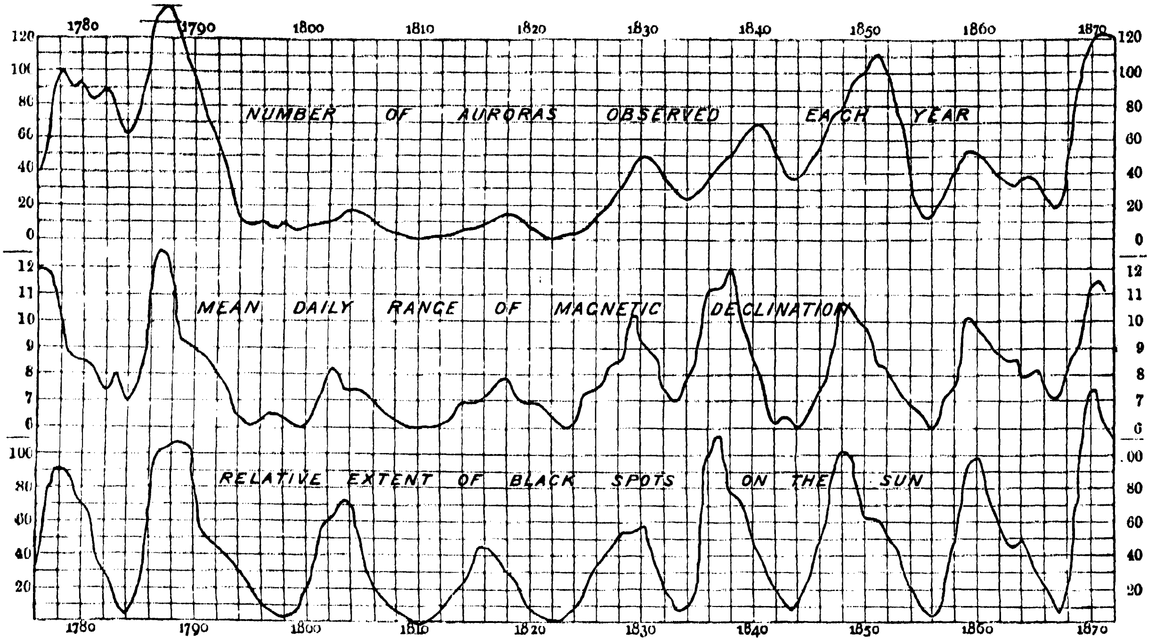

Diagram showing Correspondence of Auroræ, Magnetic Variation, and Sun Spots.

Annual distribution.

It has frequently been stated that the aurora returned periodically on certain days in the same manner as meteors. On the 3d of February brilliant auroræ occurred in 1750 and 1869, and on the 4th in 1869, 1870, 1871, 1872, 1873, and 1874; on the 13th February in 1575, 1821, 1822, 1865, and 1867; on the 6th March in 1716, 1777, 1843, 1867, and 1868; on the 9th September in 1776, 1827, 1835, 1866, 1868, 1872; and on the 29th in 1828, 1840, 1851, 1852, 1870, and 1872. This conclusion, however, is not supported by systematic investigation. A considerable catalogue of auroræ was divided into decennial periods, and it was found that the maxima of one period rarely coincided with those of others, and that the larger the number of years taken into account the less prominent the maxima appeared,—evident proof that they were only accidental. It may be, however, that if only prominent auroræ had been considered, more periodicity might have been found, or that the periodicity is constant for very short periods only.

Although no daily periodicity can be affirmed, there are two well-marked annual maxima in March and October, of which the latter is the greater, and two minima—the greater in June and the less in January. In this respect the aurora differs from the sporadic meteors, which have a maximum in autumn and a minimum in spring. It also differs from meteors in the hours of its appearance, the former being most frequent before and the latter after midnight.

Meteoric hypothesis.

Although the electric hypothesis is the one generally accepted by scientific men, it is only fair to allude to one that has been recently proposed independently by Dr Zehfuss (*Physikalische Theorie*, Adelman, Frankfort) and by H. J. H. Groneman of Gröningen (*Astronomische Nachrichten*, No. 2010–2012). According to this view, the light of the aurora is caused by clouds of ferruginous meteoric dust, which is ignited by friction with the atmosphere. Groneman has shown that these might be arranged along the magnetic curves by action of the earth's magnetic force during their descent, and that their influence might produce the observed magnetic disturbances. The arches may be accounted for by the effects of perspective on columns suddenly terminated at a uniform height by increase of atmospheric density, while the correspondences with iron lines in its spectrum are sufficiently close to favour the idea. Ferruginous particles have been found in the dust of the Polar regions (E. A. Nordenskiold, *Ast. Nach.*, 1874, § 154), but whether they are derived from stellar space or from volcanic eruption is uncertain. The yearly and eleven-yearly periodicity of auroræ tends to support the theory, but it is a formidable difficulty that, while shooting stars are more frequent in the morning, or on the face of the earth which is directed forwards in its orbit, the reverse is the case with auroræ. Groneman meets this difficulty by supposing that in the first case the velocity may be too great to allow of arrangement by the earth's magnetic force, and that, consequently, only diffused light can be produced. He accounts for its unfrequency in equatorial regions by the weakness of the earth's magnetic force, and the fact that, when it does occur, the columns must be parallel to the earth's surface. Without pronouncing in favour of this hypothesis, it must be admitted that it furnishes a plausible explanation of the phenomenon, although we have no evidence that meteoric dust, even if it exists, would produce the observed spectrum, and, as has been already remarked, the iron coincidences are of little weight.

Although we must confess that the causes of the aurora are very imperfectly explained, we may hope that the rapid progress which the last few years have witnessed in bringing terrestrial magnetism under the domain of cosmical laws may soon be extended to the aurora, and that we shall see in it fresh evidence that the same forces which cause hurricanes in the solar atmosphere thrill sympathetically to the furthest planets of our system in waves, not only of light and heat, but of magnetism and electricity.

Bibliography.

The following is a list of the most important papers, treatises, and works on this subject:—*Berlin Mem.* 1710, i. 131; Halley, *Phil. Trans.* 1716, 1719, xxix. 406, xxx. 584; Hearne, *Phil. Trans.*, xxx.

AURUNGÁBÁD, or AURANGÁBÁD, a city of India, in the native state of Haidarábád, or the Nizám's dominions, situated in 19° 51′ N. lat., and 75° 21′ E. long., 138 miles from Púna, 207 from Bombay *via* Púna, and 270 from Haidarábád. It was founded about the year 1620, under the name of Gurka, by Malik Ambar, an Abyssinian, who had risen from the condition of a slave to great influence. Subsequently it became the capital of the Moghul conquests in the south of India. Aurungzebe made it the seat of his government during his viceroyalty of the Deccan, and gave it the name of Aurungábád. It thus grew into the principal city of an extensive province of the same name, stretching westward to the sea, and comprehending nearly the whole of the territory now comprised within the northern division of the presidency of Bombay. Aurungábád long continued to be the capital of the succession of potentates bearing the modern title of Nizám, after those chiefs became independent of Delhi. They abandoned it subsequently, and transferred their capital to Haidarábád, when the town at once began to decline. It is now greatly fallen from its ancient grandeur. The city is but half-peopled, and is half in ruins, presenting everywhere the melancholy appearances of desertion and decay. The population is, however, still considerable, and in the bázár, which is very extensive, various rich commodities, particularly silks and shawls, are exposed for sale. The walls of the town are similar in their construction to those of all the other cities in this quarter of India, being rather low, with round towers.

AURUNGZEBE, one of the greatest of the Moghul emperors of Hindustan, was the third son of Shah Jehan, and was born in October 1618. His original name, Mahomet, was changed by his father, with whom he was a favourite, into Aurungzebe, meaning ornament of the throne, and at a later time he assumed the additional titles of Mohi-eddin, reviver of religion, and Alam-gir, conqueror of the world. At a very early age, and throughout his whole life, he manifested profound religious feeling, perhaps instilled into him in the course of his education under some of the strictest Mahometan doctors. He was employed, while very young, in some of his father's expeditions into the country beyond the Indus, gave promise of considerable military talents, and was appointed to the command of an army directed against the Usbeks. In this campaign he was not completely successful, and soon after was transferred to the army engaged in the Deccan. Here he gained several victories, and in conjunction with the famous general, Meer Jumla, who had deserted from the king of Golconda, he seized and plundered the town of Haidarábád, which belonged to that monarch. His father's express orders prevented Aurungzebe from following up this success, and, not long after, the sudden and alarming illness of Shah Jehan turned his thoughts in another direction. Of Shah Jehan's four sons, the eldest, Dara, a brave and honourable prince, but disliked by the Mussulmans on account of his liberality of thought, had a natural right to the throne. Accordingly, on the illness of his father, he at once seized the reins of government and established himself at Delhi. The second son, Soojah, governor of Bengal, a dissolute and sensual prince, was dissatisfied, and raised an army to dispute the throne with Dara. The keen eye of Aurungzebe saw in this conjuncture of events a favourable opportunity for realising his own ambitious schemes. His religious exercises and temperate habits gave him, in popular estimation, a great superiority over his brothers, but he was too politic to put forward his claims openly. He made overtures to his younger brother Murad, governor of Guzerat, representing that neither of their elder brothers was worthy of the kingdom, that he himself had no temporal ambition, and desired only to place a fit monarch on the throne, and then to devote himself to religious exercises and make the pilgrimage to Mecca. He therefore proposed to unite his forces to those of Murad, who would thus have no difficulty in making himself master of the empire while the two elder brothers were divided by their own strife. Murad was completely deceived by these crafty representations, and at once accepted the offer. Their united armies then moved northward. Meanwhile Shah Jehan had recovered, and though Dara resigned the crown he had seized, the other brothers professed not to believe in their father's recovery, and still pressed on. Soojah was defeated by Dara's son, but the imperial forces under Jesswunt Singh were completely routed by the united armies of Aurungzebe and Murad. Dara in person took the field against his brothers, but was defeated and compelled to fly. Aurungzebe then, by a clever stroke of policy, seized the person of his father, and threw him into confinement, in which he was kept for the remaining eight years of his life. Murad was soon removed by assassination, and the way being thus cleared, Aurungzebe, with affected reluctance, ascended the throne in August 1658. He quickly freed himself from all other competitors for the imperial power. Dara, who again invaded Guzerat, was defeated and closely pursued, and was given up by the native chief with whom he had taken refuge. He was brought to Delhi, exhibited to the people, and assassinated. Soojah, who had been a second time defeated near Allahabad, was attacked by the imperial forces under Meer Jumla and Mahomet, Aurungzebe's eldest son, who, however, deserted and joined his uncle. Soojah was defeated and fled to Aracan, where he perished; Mahomet was captured, thrown into the fortress of Gwalior, and died after seven years' confinement. No similar contest disturbed Aurungzebe's long reign of forty-six years, which has been celebrated, though with doubtful justice, as the most brilliant period in the history of Hindustan. The empire certainly was wealthy and of enormous extent, for there were successively added to it the rich kingdoms of

Bajapore and Golconda, and the barren province of Assam, but it was internally decaying, and ready to crumble away before the first vigorous assault. Two causes principally had tended to weaken the Moghul power. The one was the intense bigotry and intolerant policy of Aurungzebe, which had alienated the Hindus and roused the fierce animosity of the haughty Rajputs. The other was the rise and rapid growth of the Mahratta power. Under their able leader, Sevaji, these daring freebooters plundered in every direction, nor could all Aurungzebe's efforts avail to subdue them. At the close of the long contests between them, the Moghul power was weaker, the Mahratta stronger than at first. Still the personal ability and influence of the emperor were sufficient to keep his realms intact during his own life. His last years were embittered by remorse, by gloomy forebodings, and by constant suspicion, for he had always been in the habit of employing a system of espionage, and only then experienced its evil effects. He died, on the 21st February 1707, at Ahmadnagar, while engaged on an extensive but unfortunate expedition against the Mahrattas.

AUSCHWITZ, or Oswiecim, a town in Galicia, Austria, on the right bank of the Sola, a tributary of the Wechsel, 33 miles W.S.W. of Cracow. It has a population of upwards of 3800, and carries on a trade in salt. Previous to the first partition of Poland in 1773, it was the seat of a dukedom, which had been united by Sigismund Augustus with the duchy of Zator in 1564.

AUSCULTATION (*auscultare*, to listen), a term in medicine, applied to the method employed by physicians for determining, by the sense of hearing, the condition of certain internal organs. The ancient physicians appear to have practised a kind of auscultation, by which they were able to detect the presence of air or fluids in the cavities of the chest and abdomen. Still no general application of this method of investigation was resorted to, or was indeed possible, till the advance of the study of anatomy led to correct ideas regarding the locality, structure, and uses of the various organs of the body, and to the alterations produced in them by disease. In 1761 Auenbrugger of Vienna introduced the art of percussion in reference more especially to diseases of the chest. This consisted in tapping with the fingers the surface of the body, so as to elicit sounds by which the comparative resonance of the subjacent parts or organs might be estimated. Auenbrugger's method attracted but little attention, till Corvisart, in 1808, demonstrated its great practical importance; and then its employment in the diagnosis of affections of the chest soon became general. Percussion was originally practised in the manner above mentioned (*immediate percussion*), but subsequently the method of *mediate percussion* was introduced by Piorry, and is that now largely adopted. It is accomplished by placing upon the spot to be examined some solid substance named a *pleximeter* (stroke-measurer), upon which the percussion strokes are made either with the fingers or with a small hammer tipped with india-rubber. The pleximeter consists of a thin oval piece of ivory; but one or more fingers of the left hand applied flat upon the part answer equally well, and this is the method which most physicians adopt. Percussion must be regarded as a necessary part of auscultation, particularly in relation to the examination of the chest; for the physician who has made himself acquainted with the normal condition of that part of the body in reference to percussion is thus able to recognise by the ear alterations of resonance produced by disease. But percussion alone, however important in diagnosis, could manifestly convey only limited and imperfect information, for it could never indicate the nature or extent of functional disturbance, or distinguish between different forms of disease, even in those organs which it had proved to be in an abnormal condition, while in other cases, and notably in many affections of the heart, it could afford no assistance whatever.

In 1819 the distinguished French physician, Laennec, introduced the method of auscultation by means of the stethoscope (στῆθος, the chest, and σκοπέω, to examine), with which his name stands permanently associated. For some time previously, physicians, more especially in the hospitals of Paris, had been in the habit of applying the ear over the region of the heart for the purpose of listening to the sounds of that organ, and it was in the employment of this method that Laennec conceived the idea that these sounds might be better conveyed through the medium of some solid body interposed between his ear and the patient's chest. He accordingly, by way of experiment, rolled up a quire of paper into the form of a cylinder and applied it in the manner just mentioned, when he found, as he states, that he was able to perceive the action of the heart more distinctly than he had ever been able to do by the immediate application of his ear. He thence inferred that not merely the heart's sounds, but also those of other organs of the chest might be brought within reach of the ear by some such instrument, and he, therefore, had constructed the wooden cylinder, or stethoscope, which bears his name. This consisted of a cylindrical piece of wood, about 12 inches long, with a narrow perforation from end to end, the extremity for applying to the chest having a movable piece of conical form fitting into the cylinder, which was withdrawn by the physician while listening to the sounds of respiration, the complete instrument being used for examining the sounds of the voice and those of the heart. This instrument, though rendered portable by being made to screw into two halves, was inconveniently large and heavy, and was subsequently modified by Piorry to the form now generally used of a thin narrow cylinder of about 7 inches long, with an expansion at one end for applying to the chest, and a more or less flattened surface at the other for the ear of the listener. Having ascertained by careful observation the sounds elicited on auscultation of the healthy chest, Laennec studied the modifications of these as produced by disease; and by comparing cases with one another, and especially by investigating the state of the affected parts after death, he was able, in his celebrated *Traité de l'Auscultation médiate*, to lay the foundation for a rational system of diagnosis of the great classes of pulmonary and heart complaints. It does not, however, appear to be the case, as Laennec supposed, that *mediate auscultation* by the stethoscope is superior in an acoustic point of view to *immediate auscultation* by the unaided ear. On the contrary, sounds are heard louder by the latter than by the former method. Nevertheless, the stethoscope possesses special advantages, among the chief of which are that by its use particular areas can be examined and compared with greater accuracy; that it can be applied to all parts of the chest; and that it can be used in all cases where, from the sex or the bodily condition of the patient, the direct application of the ear is inadmissible. On the other hand, immediate auscultation is to be preferred in the examination of young children, who are readily frightened by the sight, and still more by the pressure upon them, of the stethoscope.

The whole subject of auscultation has been greatly elaborated since the time of Laennec, and while some of his opinions have been found to require modification, continued investigation only serves more clearly to demonstrate the value of this method of diagnosis, and to elicit fresh and more accurate results from its employment. Although much remains to be done in the way of the correct interpretation of the phenomena observed in auscultation, yet the facts already established are among the most important

acquisitions in the whole domain of practical medicine. The numerous diseases affecting the lungs can now be recognised and discriminated from each other with a precision which, but for auscultation and the stethoscope, would have been altogether unattainable, a point which bears most intimately upon the treatment of this great and common class of ailments. The same holds good in the case of the heart, whose varied and often complex forms of disease can, by auscultation, be identified with striking accuracy. But in addition to these its main uses, auscultation is found to render great assistance in the investigation of many obscure internal affections, such as aneurisms and certain diseases of the œsophagus and stomach. To the accoucheur the stethoscope yields valuable aid in the detection of some forms of uterine tumours, and especially in the diagnosis of pregnancy,—the auscultatory evidence afforded at a particular stage by the sounds of the fœtal heart being by far the most reliable of the many signs of that condition. (J. O. A.)

AUSONIUS, Decimus Magnus, a Roman poet of the 4th century, was the son of an eminent physician, and born at Burdigala (*Bordeaux*) about 310 A.D. His education was conducted with unusual care, either because his genius was very promising, or because the scheme of his nativity, which had been cast by his maternal grandfather, was found to promise great fame and advancement. He made extraordinary progress in classical learning; and, after completing his studies at Toulouse, he practised for a time at the bar in his native place. At the age of thirty he became a teacher of grammar, and soon afterwards was promoted to the professorship of rhetoric. In this office he acquired so great a reputation that he was appointed preceptor to Gratian, the Emperor Valentinian's son. The rewards and honours conferred on him for the faithful discharge of his duties, prove the truth of Juvenal's maxim—that when Fortune pleases she can raise a man from the humble rank of rhetorician to the dignity of consul. He was appointed consul by the Emperor Gratian in the year 379, after having filled other important offices; for besides the dignity of quæstor, to which he had been nominated by Valentinian, he was made præfect of Latium, of Libya, and of Gaul, after that prince's death. His speech, returning thanks to Gratian on his promotion to the consulship, is a good specimen of high-flown rhetorical flattery. The time of his death is uncertain, but he was alive in 388, and probably survived till about 394. From references in his works he appears to have been a convert to Christianity.

Of his prose writings, there are extant the *Actio ad Gratianum*, the *Periochæ* (or summaries) *in Iliadem et Odysseam*, and one or two of the *Epistolæ*. The principal pieces in verse are the *Epigrammata*, some of which are extremely felicitous; the *Parentalia* and *Commemoratio Professorum Burdigalensium*, which give interesting details concerning his relations and literary friends; the *Epistolæ*; and, finally, the *Idyllia*, a collection of twenty small poems, the most famous of which are the *Cento Nuptialis*, an obscene selection of lines from Virgil, and the *Mosella*, a descriptive poem on the river Moselle, containing some good passages. Ausonius was rather a man of letters than a poet; his wide reading supplied him with materials for verse, but his works exhibit no traces of a true poetic spirit; even his versification, though ingenious, is frequently defective. The best editions of his works are those of Tollius (Amsterdam, 1669), and Souchay (Paris, 1730), and the Bipontine (1785). The *Mosella* has been edited separately by Böcking (1828, 1842).

AUSPICIA. See Augurs.

AUSSIG, Aussyenad, or Labem, a town of Austria, in Bohemia, situated in a mountainous district, at the confluence of the Bila and the Elbe. It carries on a large manufacture of woollen wares, linen, paper, &c. Its chemical works alone give employment to 500 operatives, and about 600 boats are annually built in its yards. Besides a considerable trade in grain, fruit, mineral-waters, and wood, there is a large export of coal from the neighbouring mines. Aussig, once strongly fortified, was destroyed by the Hussites in 1426, burned down in 1583, and captured by the Swedes in 1639. Population, 10,933.

AUSTEN, Jane, one of the most distinguished modern British novelists, was born December 16, 1775, at the parsonage of Steventon, in Hampshire, of which place her father was for many years rector. Her life was singularly tranquil and void of incident, so that but few facts are known concerning her from which an idea of her character can be formed. She was tall and attractive in person, and of an extremely kind and gentle disposition. Under her father's care she received a sound education, though she had few of the modern accomplishments. She had a fair acquaintance with English literature, her favourite authors being Richardson, Johnson, Cowper, and Crabbe; she knew French well and Italian slightly, had some taste for music, and was noted for her skill in needlework. She was a particular favourite with all her younger relatives, especially on account of her wonderful power of extemporising long and circumstantial narratives. At a very early age she seems to have begun to exercise her faculty for composition, and wrote several short tales and fragments of larger works, some of which have been found among her papers. These first essays are written in a remarkably pure and vigorous style, and are not unworthy of her later reputation. In 1796 her first large work, *Pride and Prejudice*, was begun and completed in about ten months; *Sense and Sensibility* and *Northanger Abbey* were written soon after, during 1797 and 1798. Many years elapsed before these works were published, for the first attempts to introduce them to the public were badly received. *Pride and Prejudice* was summarily rejected by Mr Cadell; *Northanger Abbey* was sold for £10 to a Bath publisher, but was never printed, and, many years after, was bought back by the author. From 1801 to 1805 the Austen family resided in Bath, they then removed to Southampton, and finally, in 1809, settled at Chawton. There Miss Austen, who for some years had written nothing, resumed her pen, and began to prepare for publication her early novels. *Sense and Sensibility* was published in 1811, *Pride and Prejudice* in 1813, *Mansfield Park* in 1814, *Emma* in 1816. These four were anonymous. *Northanger Abbey* and *Persuasion* appeared together under Miss Austen's name in 1818, after her death. Early in 1816 her health had begun to give way; her strength gradually declined, and on the 18th July 1817, she died at Winchester, whither she had removed for change of air and scenery. She was buried in the cathedral of that town.

Miss Austen's works at the time of their appearance were on the whole well received, and brought her considerable reputation,—more, indeed, than she had herself anticipated; but their full merits were not then so generally recognised as they have since been. The novels most popular at that time belonged to the class of which Mrs Radcliffe's *Udolpho*, Godwin's *St Leon* or *Caleb Williams*, and Lewis's *Monk* are the best known representatives. Against this style of fiction Miss Austen from the first set her face; she had a remarkably keen sense of humour, and the ludicrous aspect of these thrilling incidents, mysterious situations, and unnatural characters, presented itself very strongly to her mind. *Northanger Abbey*, one of her earliest productions, is a clever and well-sustained parody on romances of this type. She did not, however, confine herself to mere negative criticism, but resolved to show that the interest of readers could be roused and sustained by a story absolutely free from the whole machinery of romance and exaggerated sentiment, but presenting an accurately-drawn picture of quiet, natural life. This task she accomplished with complete success; she was the first

to introduce the novel of domestic life, and her writings are still the best specimens of that class of fiction. It could hardly be expected that such works would become immediately popular; the characters, the motives of action, and the plot itself were too ordinary, one may say too commonplace, to appeal strongly to the sympathies of the general mass of readers. Her colours were not showy enough to strike the vulgar eye. It is probable, indeed, that her admirers will always be few in number; for not only does it require a somewhat cultivated taste to appreciate the rare skill with which the scanty materials of her tales are handled, but the author's experience of life was so limited that her works are entirely wanting in certain elements—such as depth of feeling and breadth of sympathy—which are indispensable before a work of fiction can exercise any considerable influence on the public mind.

The framework in nearly all Miss Austen's novels is the same, taken as they are from ordinary English middle-class life; her characters are in no way distinguished by any remarkable qualities, they are such persons as one would readily expect to meet in every-day life; the plot is exceedingly simple, and the incidents, never rising above the level of the most common-place occurrences, flow naturally from the characters of the actors. In the hands of most writers such materials would infallibly become monotonous and tiresome; but from any danger of this Miss Austen is completely freed by her wonderful power of exciting interest in the "involvements and feelings of ordinary life," and the skill with which, by a series of imperceptible but effective touches, she discriminates her characters, rounds them off, and makes them stand out from the canvas real and living personages. Her gallery of portraits is certainly small, and the same character appears over and over again, but each figure is so distinctly drawn, and has such marked individuality, that one is never struck with a sense of repetition. A warm admirer of her works, Archbishop Whately, has compared them to the carefully-executed pictures of the Dutch school; perhaps the analogy of miniature painting, suggested by the author herself, is more happy and expressive.

Miss Austen's life has been written by her nephew, Rev. J. Austen-Leigh (1870, 2d ed., 1871), who has also published some extracts from her papers, including a short tale, *Lady Susan*, written in the form of letters; a fragment of a larger work called *The Watsons;* the first draft of a chapter in *Persuasion;* and the beginning of a novel, on which she was engaged at the time of her death.

AUSTERLITZ, a small town of Moravia, 12 miles E.S.E. of Brünn, containing a magnificent palace belonging to the prince of Kaunitz-Rietberg, and a beautiful church. It has been rendered memorable by the great victory obtained in its vicinity, on the 2d December 1805, by the French under Napoleon, over the united forces of Austria and Russia under their emperors. Population, 3450.

AUSTIN, John, one of the ablest English writers on jurisprudence, was born on the 3d March 1790. At an early age he entered the army, and passed five years in military service. He then retired, applied himself to the study of law, and was called to the bar in 1814. His powers, though admirably adapted for grasping the fundamental principles of law, were not of a nature to render him successful in legal practice. His health, too, was delicate, and in 1825 he resigned active employment at the bar. In the following year, however, he was appointed to the chair of jurisprudence in the newly-founded London university. He immediately crossed over to Germany to prepare himself for his new duties, and at Bonn became acquainted with some of the most eminent German jurists. His lectures were at first attended by a number and a class of students quite beyond his anticipations. Among his hearers were such men as Lord Romilly, Sir G. C. Lewis, and J. S. Mill. From Mill's notes some of the lectures were afterwards published, and he has given an admirable account of Austin in his *Dissertations* (vol. iii.) But it soon became apparent that there would be no steady demand for training in the science of law, which, though useful, was not of immediate utility in practice. Under these circumstances Austin, who was almost too conscientious in regard to his own work, thought it right to resign the chair in 1832. An attempt to institute lectures at the Inner Temple also failed, and, as his health was delicate, he retired to Boulogne, where he remained for nearly two years. In 1837 he acted as royal commissioner in Malta, and discharged the duties of that office most efficiently. The next ten years were spent in travelling on the Continent, as the state of his health hardly permitted him to reside in England. The Revolution of 1848 drove him from Paris, and on his return to England he settled at Weybridge, in Surrey, where he remained till his death in December 1859. Austin wrote one or two pamphlets, but the chief work he published was his *Province of Jurisprudence Determined* (1832), a treatise on the relation between ethics and law, which gives a clear analysis of the notion of obligation, and an admirable statement of utilitarianism, the ethical theory adopted by the author. After his death, his widow, Mrs Sarah Austin, published his *Lectures on Jurisprudence; or, The Philosophy of Positive Law.* These, combined with the *Province*, have been edited, under the same title, by Mr R. Campbell, and reached in 1875 a fifth edition.

AUSTIN, Sarah Taylor, translator and miscellaneous writer, was born in 1793. She was one of the Taylor family of Norwich, several of whose members had distinguished themselves in the fields of literature and science. She was the youngest child of her family, received a liberal and solid education at home, chiefly from her mother, and had the advantage, too, of enjoying in her father's house much intellectual society. She grew up a beautiful and cultivated woman, and in 1820 became the wife of John Austin, noticed above. They settled in London, and among the familiar visitors of their house were Bentham, the Mills (father and son), the Grotes, Romilly, Buller, Sydney Smith, and other eminent men. She accompanied her husband in 1827 to Bonn, where they spent some months, and made acquaintance with Niebuhr, Schlegel, Arndt, and other distinguished Germans. She afterwards lived some years in Germany and France, and was left a widow in December 1859. Mrs Austin is best known as a singularly skilful translator of German and French works. In 1832 appeared her version of the *Travels of Prince Puckler Muskau.* This was followed by *Characteristics of Goethe* from the German of Falk, *History of the Reformation in Germany* and *History of the Popes* from the German of Ranke, and Dr Carove's *Story without an End.* She contributed "Travelling Letters" and critical and obituary notices to the *Athenæum*, edited the *Memoir of Sydney Smith* and her daughter Lady Duff Gordon's *Letters from Egypt*, and for some years of her widowhood was occupied in arranging for publication her husband's *Lectures on Jurisprudence.* She was also author of *Germany from* 1760 *to* 1814, *National Education*, and *Letters on Girls' Schools.* Mrs Austin died at Weybridge in Surrey, 8th August 1867.

AUSTRALASIA, one of the six great geographical divisions of the globe, is situated, as its name indicates, south of Asia, between the equator and 50° S. lat., and 110° and 180° E. long. It comprises the island-continents of New Guinea, Australia, Tasmania, and New Zealand, and the conterminous archipelagoes of New Britannia, Solomon Islands, New Hebrides, Loyalty Islands, and New Caledonia, which will be treated of under special headings.

ENCYCLOPÆDIA BRITANNICA NINTH EDITION.

AUSTRALIA

late II. AUSTRALIA or New Holland, the largest island-continent of Australasia, is situated within 10° 47′ and 39° 11′ S. lat., and 113° and 153° 30′ E. long. It measures 2500 miles in length from west to east, by 1950 miles in breadth from north to south, and contains an area of about 3,000,000 square miles—nearly the same as that of the United States of America, exclusive of Alaska. It is surrounded on the west by the Indian Ocean, and on the east by the South Pacific. In the north it is separated

Sketch Map of Australia.

from New Guinea by Torres Strait, which is 80 miles broad, and from the Eastern Archipelago by Arafura Sea; while on the south Bass Strait, 140 miles wide, separates it from Tasmania. The neighbouring colony of New Zealand lies 1200 miles opposite its south-east coast.

Owing to its position at the antipodes of the civilised world, Australia has been longer a *terra incognita* than any other region of the same extent. Its first discovery is involved in considerable doubt, from confusion of the names which were applied by the earlier navigators and geographers to the Australasian coasts.

The ancients were somehow impressed with the idea of a *Terra Australis* which was one day to be revealed. The Phœnician mariners had pushed through the outlet of the Red Sea to eastern Africa, the Persian Gulf, and the coasts of India and Sumatra. But the geographer Ptolemy, in the 2d century, still conceived the Indian Ocean to be an inland sea, bounded on the south by an unknown land, which connected the *Chersonesus Aurea* (Malay Peninsula) with the promontory of *Prasum* in eastern Africa. This erroneous notion prevailed in mediæval Europe, although some travellers like Marco Polo heard rumours in China of large insular countries to the south-east.

The investigations of Mr R. H. Major make it appear probable that the Australian mainland was known as "Great Java" to the Portuguese early in the 16th century; and the following passage in the *Descriptionis Ptolemaicæ Augmentum* of Cornelius Wytfliet, printed at Louvain in 1598, is perhaps the first distinct account that occurs of the country:—"The *Australis Terra* is the most southern of all lands, and is separated from New Guinea by a narrow strait. Its shores are hitherto but little known, since, after one voyage and another, that route has been deserted, and seldom is the country visited, unless when sailors are driven there by storms. The *Australis Terra* begins at one or two degrees from the equator, and is ascertained by some to be of so great an extent, that if it were thoroughly explored it would be regarded as a fifth part of the world."

It was in 1606 that Torres, with a ship commissioned by the Spanish Government of Peru, parted from his companion Quiros (after their discovery of Espiritu Santo and the New Hebrides), and sailed from east to west through the strait which bears his name; while in the same year the peninsula of Cape York was touched at by a vessel called the "Duyfhen" or "Dove" from the Dutch colony of Bantam in Java, but this was understood at the time to form a part of the neighbouring island of New Guinea. The Dutch continued their attempts to explore the unknown land, sending out in 1616 the ship "Endraght," commanded by Dirk Hartog, which sailed along the west coast of Australia from lat. 26° 30′ to 23° S. This expedition left on an islet near Shark's Bay a record of its visit engraved on a tin plate, which was found there in 1801. The "Pera" and "Arnhem," Dutch vessels from Amboyna, in 1618 explored the Gulf of Carpentaria, giving to its westward peninsula, on the side opposite to Cape York, the name of Arnhem Land. The name of Carpentaria was also bestowed on this vast gulf in compliment to Peter Carpenter, then governor of the Dutch East India Company. In 1627 the "Guldene Zeepard," carrying Peter Nuyts to the embassy in Japan, sailed along the south coast from Cape Leeuwin, and sighted the whole shore of the Great Bight. But alike on the northern and southern seaboard, the aspect of New Holland, as it was then called presented an uninviting appearance.

An important era of discovery began with Tasman's voyage of 1642. He, too, sailed from Batavia; but, first crossing the Indian Ocean to the Mauritius, he descended to the 44th parallel of S. lat., recrossing that ocean to the east. By taking this latter course he reached the island which now bears his name, but which he called Van Diemen's Land, after the Dutch governor of Batavia. In 1644 Tasman made another attempt, when he explored the north-west coast of Australia, from Arnhem Land to the 22d degree of latitude, approaching the locality of Dirk Hartog's discoveries of 1616. He seems to have landed at Cape Ford, near Victoria River, also in Roebuck Bay, and again near Dampier's Archipelago. But the hostile attitude of the natives, whom he denounced as a malicious and miserable race of savages, prevented his seeing much of the new country; and for half a century after this no fresh discoveries were made.

The English made their first appearance on the Australian coast in 1688, when the north-western shores were visited by the famous buccaneer Captain William Dampier, who spent five weeks ashore near Roebuck Bay. A few years later (1697) the Dutch organised another expedition under Vlamingh, who, first touching at Swan River on the west coast, sailed northward to Shark's Bay, where Hartog had been in 1616. Dampier, two years later, visited the same place, not now as a roving adventurer, but with a commission from the English Admiralty to pursue his Australian researches. This enterprising navigator, in the narrative of his voyages, gives an account of the trees, birds, and reptiles he observed, and of his encounters with the natives. But he found nothing to invite a long stay. There was

yet another Dutch exploring squadron on that coast in 1705, but the results were of little importance.

It was Captain Cook, in his voyages from 1769 to 1777, who communicated the most important discoveries, and first opened to European enterprise and settlement the Australasian coasts. In command of the bark "Endeavour," 370 tons burden, and carrying 85 persons, amongst whom were Sir Joseph Banks and Dr Solander, returning from the Royal Society's expedition to observe the transit of Venus, Cook visited both New Zealand and New South Wales. He came upon the Australian mainland in April 1770, at a point named after Lieutenant Hicks, who first sighted it, on the shore of Gipps' Land, Victoria, S. lat. 38°, E. long. 148° 53′. From this point, in a coasting voyage not without peril when entangled in the barrier reefs of coral, the little vessel made its way up the whole length of the eastern side of Australia, rounding Cape York, and crossing Torres Strait to New Guinea. In his second expedition of Australasian discovery, which was sent out in 1773, Cook's ship, the "Resolute," started in company with the "Adventure," commanded by Captain Furneaux. The two vessels separated, and Cook went to New Zealand, while Furneaux examined some parts of Tasmania and Bass Strait. The third voyage of Cook brought him, in 1777, both to Tasmania and to New Zealand.

Next to Cook, twenty or thirty years after his time, the names of Bass and Flinders are justly honoured for continuing the work of maritime discovery he had so well begun. To their courageous and persevering efforts, begun at their private risk, is due the correct determination of the shape both of Tasmania and the neighbouring continent. The French admiral Entrecasteaux, in 1792, had made a careful examination of the inlets at the south of Tasmania, and in his opinion the opening between Tasmania and Australia was only a deep bay. It was Bass who discovered it to be a broad strait, with numerous small islands. Captain Flinders survived his friend Bass, having been associated with him in 1798 in this and other useful adventures. Flinders afterwards made a complete survey in detail of all the Australian coasts, except the west and north-west. He was captured, however, by the French during the war, and detained a prisoner in Mauritius for seven years.

The shores of what is now the province of Victoria were explored in 1800 by Captain Grant, and in 1802 by Lieutenant Murray, when the spacious land-locked bay of Port Phillip was discovered. New South Wales had already been colonised, and the town of Sydney founded at Port Jackson in 1788. West Australia had long remained neglected, but in 1837, after the settlement at Swan River, a series of coast surveys was commenced in H.M.S. "Beagle." These were continued from 1839 to 1843 by Mr Stokes, and furnished an exact knowledge of the western, north-western, and northern shores, including four large rivers.

Inland Exploration.—The geographical position of the Australian continent had now been sufficiently determined, and what remained for discovery was sought, not as hitherto by coasting along its shores and bays, but by striking into the vast tract of *terra incognita* that occupied the interior. The colony of New South Wales had been founded in 1788, but for twenty-five years its settlers were acquainted only with a strip of country 50 miles wide, between the Blue Mountains and the sea-coast, for they scarcely ever ventured far inland from the inlets of Port Jackson and Botany Bay. Mr Bass, indeed, once while waiting for his vessel, made an attempt to cross the Blue Mountains, and succeeded in discovering the River Grove, a tributary of the Hawkesbury, but did not proceed further. An expedition was also conducted by Governor Hunter along the Nepean River west of the settlement, while Lieutenant Bareiller, in 1802, and Mr Caley, a year or two later, failed in their endeavour to surmount the Blue Mountain range. This formidable ridge attains a height of 3400 feet, and being intersected with precipitous ravines 1500 feet deep, presented a bar to these explorers' passage inland. At last, in 1813, when a summer of severe drought had made it of vital importance to find new pastures, three of the colonists, Messrs Wentworth and Blaxland and Lieutenant Lawson, crossing the Nepean at Emu Plains, gained sight of an entrance, and ascending the summit of a dividing ridge, obtained a view of the grassy valley of the Fish River. This stream runs westward into the Macquarie, which was discovered a few months afterwards by Mr Evans, who followed its course across the fertile plains of Bathurst.

In 1816 Lieutenant Oxley, R.N., accompanied by Mr Evans and Mr Cunningham the botanist, conducted an expedition of great interest down the Lachlan River, 300 miles to the north-west, reaching a point 34° S. lat., and 144° 30′ E. long. On his return journey Oxley again struck the Macquarie River at a place he called Wellington, and from this place in the following year he organised a second expedition in hopes of discovering an inland sea. He was, however, disappointed in this, as after descending the course of the Macquarie below Mount Harris, he found that the river ended in an immense swamp overgrown with reeds. Oxley now turned aside—led by Mr Evans's report of the country eastward—crossed the Arbuthnot range, and traversing the Liverpool Plains, and ascending the Peel and Cockburn Rivers to the Blue Mountains, gained sight of the open sea, which he reached at Port Macquarie. A valuable extension of geographical knowledge had been gained by this circuitous journey of more than 800 miles. Yet its result was a disappointment to those who had looked for means of inland navigation by the Macquarie River, and by its supposed issue in a Mediterranean sea.

During the next two or three years public attention was occupied with Captain King's maritime explorations of the north-west coast in three successive voyages, and by explorations of West Australia in 1821. These steps were followed by the foundation of a settlement on Melville Island, in the extreme north, which, however, was soon abandoned. In 1823 Lieutenant Oxley proceeded to Moreton Bay and Port Curtis, the first place 7° north of Sydney, the other 10°, to choose the site of a new penal establishment. From a shipwrecked English sailor he met with, who had lived with the savages, he heard of the river Brisbane. About the same time, in the opposite direction, south-west of Sydney, a large extent of the interior was revealed. The River Murrumbidgee—which unites with the Lachlan to join the great River Murray—was traced by Mr Hamilton Hume and Mr Hovell into the country lying north of the province of Victoria, through which they made their way to Port Phillip. In 1827 and the two following years, Mr Cunningham prosecuted his instructive explorations on both sides of the Liverpool range, between the upper waters of the Hunter and those of the Peel and other tributaries of the Brisbane north of New South Wales. Some of his discoveries, including those of Pandora's Pass and the Darling Downs, were of great practical utility.

By this time much had thus been done to obtain an acquaintance with the eastern parts of the Australian continent, although the problem of what could become of the large rivers flowing north-west and south-west into the interior was still unsolved. With a view to determine this question, Governor Sir Ralph Darling, in the year 1828, sent out the expedition under Captain Charles Sturt, who proceeding first to the marshes at the end of the Macquarie River, found his progress checked by the dense mass of reeds in that quarter. He therefore turned westward

and struck a large river, with many affluents, to which he gave the name of the Darling. This river, flowing from north-east to south-west, drains the marshes in which the Macquarie and other streams from the south appeared to be lost. The course of the Murrumbidgee, a deep and rapid river, was followed by the same eminent explorer in his second expedition in 1831 with a more satisfactory result. He travelled on this occasion nearly 2000 miles, and discovered that both the Murrumbidgee, carrying with it the waters of the Lachlan morass, and likewise the Darling, from a more northerly region, finally joined another and larger river. This stream, the Murray, in the upper part of its course, runs in a north-westerly direction, but afterwards turning southwards, almost at a right angle, expands into Lake Alexandrina on the south coast, about 60 miles S.E. of the town of Adelaide, and finally enters the sea at Encounter Bay in E. long. 139°.

After gaining a practical solution of the problem of the destination of the westward-flowing rivers, Sir Thomas Mitchell, in 1835, led an expedition northward to the upper branches of the Darling; but the party meeting with a sad disaster in the death of Mr Cunningham, the eminent botanist, who was murdered by the natives on the Bogan River, further exploration of that region was left to be undertaken by Dr Leichardt, nine years later, and by the son of Sir Thomas Mitchell. Meantime, from the new colony of Adelaide, South Australia, on the shores of Gulf St Vincent, a series of adventurous journeys to the north and to the west was commenced by Mr Eyre, who explored a country much more difficult of access, and more forbidding in aspect, than the "Riverina" of the eastern provinces. He performed in 1840 a feat of extraordinary personal daring, travelling all the way along the barren sea-coast of the Great Australian Bight, from Spencer Gulf to King George's Sound. Mr Eyre also explored the interior north of the head of Spencer Gulf, where he was misled, however, by appearances to form an erroneous theory about the water-surfaces named Lake Torrens. It was left to the veteran explorer, Sturt, to achieve the arduous enterprise of penetrating from the Darling northward to the very centre of the continent. This was in 1845, the route lying for the most part over a stony desert, where the heat (reaching 131° Fahr.), with scorching winds, caused much suffering to the party. The most northerly point reached by Sturt on this occasion was about S. lat. 24° 25′. His unfortunate successors, Burke and Wills, travelled through the same district sixteen years later; and other expeditions were organised, both from the north and from the south, which aimed at learning the fate of these travellers, as well as that of Dr Leichardt. These efforts completed our knowledge of different routes across the entire breadth of Australia, in the longitude of the Gulf of Carpentaria; while the enterprising journeys of MacDouall Stuart, a companion of Sturt, obtained in 1862 a direct passage from South Australia northward to the shores of the Malayan Sea. This route has been utilised by the construction of an overland telegraph from Adelaide to the northern coast.

A military station having been fixed by the British Government at Port Victoria, on the coast of Arnhem Land, for the protection of shipwrecked mariners on the north coast, it was thought desirable to find an overland route between this settlement and Moreton Bay, in what then was the northern portion of New South Wales, now called Queensland. This was the object of Dr Leichardt's expedition in 1844, which proceeded first along the banks of the Dawson and the Mackenzie, tributaries of the Fitzroy River, in Queensland. It thence passed farther north to the Burdekin, ascending to the source of that river, and turned westward across a table-land, from which there was an easy descent to the Gulf of Carpentaria. Skirting the low shores of this gulf, all the way round its upper half to the Roper, Leichardt crossed Arnhem Land to the Alligator River, which he descended to the western shore of the peninsula, and arrived at Port Victoria, otherwise Port Essington, after a journey of 3000 miles, performed within a year and three months. In 1847 Leichardt undertook a much more formidable task, that of crossing the entire continent from east to west. His starting point was on the Fitzroy Downs, north of the River Condamine, in Queensland, between the 26th and 27th degrees of S. latitude. But this eminent explorer had not proceeded far into the interior before he met his death, his last despatch dating from the Cogoon, April 3, 1848. In the same region, from 1845 to 1847, Sir Thomas Mitchell and Mr E. B. Kennedy explored the northern tributaries of the Darling, and a river in S. lat. 24°, named the Barcoo or Victoria, which flows to the south-west. This river was more thoroughly examined by Mr. A. C. Gregory in 1858. Mr Kennedy lost his life in 1848, being killed by the natives while attempting to explore the peninsula of Cape York, from Rockingham Bay to Weymouth Bay.

Among the performances of less renown, but of much practical utility in surveying and opening new paths through the country, we may mention that of Captain Banister, showing the way across the southern part of West Australia, from Swan River to King George's Sound, and that of Messrs Robinson and G. H. Haydon in 1844, making good the route from Port Phillip to Gipps' Land with loaded drays, through a dense tangled scrub, which had been described by Strzelecki as his worst obstacle. Again, in West Australia there were the explorations of the Arrowsmith, the Murchison, the Gascoyne, and the Ashburton Rivers, by Captain Grey, Mr Roe, Governor Fitzgerald, Mr R. Austin, and the brothers Gregory, whose discoveries have great importance from a geographical point of view.

These local researches, and the more comprehensive attempts of Leichardt and Mitchell to solve the chief problems of Australian geography, must yield in importance to the grand achievement of Mr Stuart in 1862. The first of his tours independently performed, in 1858 and 1859, were around the South Australian lakes, namely, Lake Torrens, Lake Eyre, and Lake Gairdner. These waters had been erroneously taken for parts of one vast horseshoe or sickle-shaped lake, only some twenty miles broad, believed to encircle a large portion of the inland country, with drainage at one end by a marsh into Spencer Gulf. The mistake, shown in all the old maps of Australia, had originated in a curious optical illusion. When Mr Eyre viewed the country from Mount Deception in 1840, looking between Lake Torrens and the lake which now bears his own name, the refraction of light from the glittering crust of salt that covers a large space of stony or sandy ground produced an appearance of water. The error was discovered, after eighteen years, by the explorations of Mr Babbage and Major Warburton in 1858, while Mr Stuart, about the same time, gained a more complete knowledge of the same district.

A reward of £10,000 having been offered by the Legislature of South Australia to the first man who should traverse the whole continent from south to north, starting from the city of Adelaide, Mr Stuart resolved to make the attempt. He started in March 1860, passing Lake Torrens and Lake Eyre, beyond which he found a pleasant, fertile country till he crossed the M'Donnell range of mountains, just under the line of the tropic of Capricorn. On the 23d of April he reached a mountain in S. lat. nearly 22°, and E. long. nearly 134°, which is the most central marked point of the Australian continent, and has been named Central Mount Stuart. Mr Stuart did not finish his task on

this occasion, on account of indisposition and other causes. But the 18th degree of latitude had been reached, where the watershed divided the rivers of the Gulf of Carpentaria from the Victoria River, flowing towards the north-west coast. He had also proved that the interior of Australia was not a stony desert, like the region visited by Sturt in 1845. On the first day of the next year, 1861, Mr Stuart again started for a second attempt to cross the continent, which occupied him eight months. He failed, however, to advance further than one geographical degree north of the point reached in 1860, his progress being arrested by dense scrubs and the want of water.

Meanwhile, in the province of Victoria, by means of a fund subscribed among the colonists and a grant by the Legislature, the ill-fated expedition of Messrs Burke and Wills was started. It made for the Barcoo, with a view to reach the Gulf of Carpentaria by a northerly course midway between Sturt's track to the west and Leichardt's to the east. The leading men of the party were Mr Robert O'Hara Burke, an officer of police, and Mr William John Wills, of the Melbourne observatory. Messrs Burke and Wills, with two men named Gray and King, left the others behind at the Barcoo on 16th December 1860, and proceeded, with a horse and six camels, over the desert traversed by Sturt fifteen years before. They got on in spite of great difficulties, past the M'Kinlay range of mountains, S. lat. 21° and 22°, and then reached the Flinders River, which flows into the head of the Gulf of Carpentaria. Here, without actually standing on the sea-beach of the northern shore, they met the tidal waters of the sea. On February 23, 1861, they commenced the return journey, having in effect accomplished the feat of crossing the Australian continent. Unhappily, three of the party perished on the road home. Gray, who had fallen ill, died on the 16th of April. Five days later, Burke, Wills, and King had repassed the desert to the place on Cooper Creek (the Barcoo, S. lat. 27° 40′, E. long. 140° 30′), where they had left the depôt, with the rest of the expedition. Here they experienced a cruel disappointment. The depôt was abandoned; the men in charge had quitted the place the same day, believing that Burke and those with him were lost. The main body of the expedition, which should have been led up by a Mr Wright, from Menindie, on the Darling, was misconducted and fatally delayed. Burke, Wills, and King, when they found themselves so fearfully left alone and unprovided in the wilderness, wandered about in that district till near the end of June. They subsisted miserably on the bounty of some natives, and partly by feeding on the seeds of a plant called nardoo. At last both Wills and Burke died of starvation. King, the sole survivor, was saved by meeting the friendly blacks, and was found alive in September by Mr A. W. Howitt's party, sent on purpose to find and relieve that of Burke.

Four other parties, besides Howitt's, were sent out that year from different Australian provinces. Three of them, respectively commanded by Mr Walker, Mr Landsborough, and Mr Norman, sailed to the north, where the latter two landed on the shores of the Gulf of Carpentaria, while Mr Walker marched inland from Rockhampton. The fourth party, under Mr J. M'Kinlay, from Adelaide, made for the Barcoo by way of Lake Torrens. By these means, the unknown region of Mid Australia was simultaneously entered from the north, south, east, and west, and important additions were made to geographical knowledge. Landsborough crossed the entire continent from north to south, between February and June 1862; and M'Kinlay, from south to north, before the end of August in that year. The interior of New South Wales and Queensland, all that lies east of the 140th degree of longitude, was examined. The Barcoo and its tributary streams were traced from the Queensland mountains, holding a south-westerly course to Lake Eyre in South Australia; the Flinders, the Gilbert, the Gregory, and other northern rivers watering the country towards the Gulf of Carpentaria were also explored. These valuable additions to Australian geography were gained through humane efforts to relieve the lost explorers. The bodies of Burke and Wills were recovered and brought to Melbourne for a solemn public funeral, and a noble monument has been erected to their honour.

Mr Stuart, in 1862, made his third and final attempt to traverse the continent from Adelaide along a central line, which, inclining a little westward, reaches the north coast of Arnhem Land, opposite Melville Island. He started in January, and on April 7 reached the farthest northern point, near S. lat. 17°, where he had turned back in May of the preceding year. He then pushed on, through a very thick forest, with scarcely any water, till he came to the streams which supply the Roper, a river flowing into the western part of the Gulf of Carpentaria. Having crossed a table-land of sandstone which divides these streams from those running to the western shores of Arnhem Land, Mr Stuart, in the month of July, passed down what is called the Adelaide River of North Australia. Thus he came at length to stand on the verge of the Indian Ocean; "gazing upon it," a writer has said, "with as much delight as Balboa, when he had crossed the Isthmus of Darien from the Atlantic to the Pacific." The line crossing Australia which was thus explored has since been occupied by the electric telegraph connecting Adelaide, Melbourne, Sydney, and other Australian cities with London.

A third part, at least, of the interior of the whole continent, between the central line of Stuart and the known parts of West Australia, from about 120° to 134° E. long., an extent of half a million square miles, still remained a blank in the map. But the two expeditions of 1873, conducted by Mr Gosse and Colonel Egerton Warburton, have made a beginning in the exploration of this *terra incognita* west of the central telegraph route. That line of more than 1800 miles, having its southern extremity at the head of Spencer Gulf, its northern at Port Darwin, in Arnhem Land, passes Central Mount Stuart, in the middle of the continent, S. lat. 22°, E. long. 134°. Mr Gosse, with men and horses provided by the South Australian Government, started on April 21 from the telegraph station fifty miles south of Central Mount Stuart, to strike into West Australia. He passed the Reynolds range and Lake Amadeus in that direction, but was compelled to turn south, where he found a tract of well-watered grassy land. A singular rock of conglomerate, 2 miles long, 1 mile wide, and 1100 feet high, with a spring of water in its centre, struck his attention. The country was mostly poor and barren, sandy hillocks, with scanty growth of spinifex. Mr. Gosse, having travelled above 600 miles, and getting to 26° 32′ S. lat. and 127° E. long., two degrees within the West Australian boundary, was forced to return. Meantime a more successful attempt to reach the western coast from the centre of Australia has been made by Colonel Warburton, with thirty camels, provided by Mr T. Elder, M.L.C., of South Australia. Leaving the telegraph line at Alice Springs (23° 40′ S. lat. 133° 14′ E. long.), 1120 miles north of Adelaide city, Warburton succeeded in making his way to the De Grey River, West Australia. Overland routes have now been found possible, though scarcely convenient for traffic, between all the widely separated Australian provinces. In Northern Queensland, also, there have been several recent explorations, with results of some interest. That performed by Mr. W. Hann, with Messrs Warner, Tate, and Taylor, in 1873,

related to the country north of the Kirchner range, watered by the Lynd, the Mitchell, the Walsh, and the Palmer Rivers, on the east side of the Gulf of Carpentaria. The coasting expedition of Mr G. Elphinstone Dalrymple, with Messrs Hill and Johnstone, finishing in December 1873, effected a valuable survey of the inlets and navigable rivers in the Cape York peninsula. The Endeavour River, in S. lat. 16°, which was visited by Captain Cook a hundred years ago, seems capable of being used for communication with the country inland. A newly discovered river, the Johnstone or Gladys, is said to flow through a very rich land, producing the finest cedars, with groves of bananas, nutmeg, ginger, and other tropical plants. The colonial geologists predict that the north-east corner of Australia will be found to possess great mineral treasures. At the opposite extremity of the continent, its south-west corner, a tour lately made by Mr A. Forrest, Government surveyor, from the Swan River eastward, and thence down to the south coast, has shown the poorness of that region. The vast superiority of eastern Australia to all the rest is the most important practical lesson taught by the land-exploring labours of the last half century.

Physical Description.—The continent of Australia, with a circumference of nearly 8000 miles, presents a contour wonderfully devoid of inlets from the sea, except upon its northern shores, where the coast line is largely indented. The Gulf of Carpentaria, situated in the north, is enclosed on the east by the projection of Cape York, and on the west by Arnhem Land, and forms the principal bay on the whole coast, measuring about 6° of long. by 6° of lat. Further to the west, Van Diemen's Gulf, though much smaller, forms a better protected bay, having Melville Island between it and the ocean; while beyond this Queen's Channel and Cambridge Gulf form inlets about S. lat. 14° 50′. On the north-west of the continent the coast line is much broken, the chief indentations being Admiralty Gulf, Collier Bay, and King Sound, on the shores of Tasman Land. Western Australia, again, is not favoured with many inlets—Exmouth Gulf and Shark Bay being the only bays of any size. The same remark may be made of the rest of the sea-board; for, with the exception of Spencer Gulf, the Gulf of St Vincent, and Port Phillip, on the south, and Moreton Bay, Hervey Bay, and Broad Sound, in the east, the coast line is singularly uniform.

The conformation of the interior of Australia is very peculiar, and may perhaps be explained by the theory of the land having been, at a comparatively recent period, the bed of an ocean. The mountain ranges parallel to the east and west coasts would then have existed as the cliffs and uplands of many groups of islands, in widely scattered archipelagoes resembling those of the Pacific. The singular positions and courses of some of the rivers lend force to this supposition. The Murray and its tributaries, the Murrumbidgee, the Lachlan, and the Darling, rising from the mountains on the east coast, flow inwards so far that they were at one time supposed to issue in a central sea. They do, in fact, spend their waters in a large shallow lake; but this is not far from the south coast, and is provided with an outlet to the ocean. The Macquarie and the Lachlan merge in extensive swamps, and their beds in the dry season become a mere chain of ponds. This agrees with the idea that the whole country was a sea-bottom, which has scarcely yet assumed the character of permanent dry land, while another proof consists in the thinness and sterility of the soil in the lowlands.

Along the entire line of the east coast there extends a succession of mountain ranges from Portland, in Victoria, to Cape York in the extreme north, called in different parts the Australian Grampians, the Australian Alps, the Blue Mountains, the Liverpool Range, and other names. These constitute, like the Andes of South America, a regular Cordillera, stretching from north to south 1700 miles in length, with an average height of 1500 feet above the sea. The rivers flowing down the eastern slope, having but short courses before they reach the sea, are of a more determined character than those which take a westerly and inland direction. They cut their way through the sandstone rocks in deep ravines; but from their tortuous and violent course, and from the insufficient volume of water, they are unfit for navigation. Very few of them traverse more than 200 miles, inclusive of windings, or pass through any district extending more than 50 miles inland. It is different with the Murray, flowing westward, which has a course of 1100 miles, traversing a space from east to west measuring 8° of longitude. The Murray is navigable during eight months of the year along a great part of its course. This great river, with its tributaries, drains a basin the area of which is reckoned at half a million of square miles. Yet it has no proper outlet to the sea, debouching into a lagoon called Lake Alexandrina, on the sea-coast of Encounter Bay. On the opposite or north-western part of the continent there are several important water-courses. One river, the Victoria, which rises somewhere about 18° or 19° S. lat. and 131° E. long., flows northward to 15° 30′ S. lat., where it turns westward. Its bed forms a deep channel through the sandstone table-land, with cliffs 300 feet high, while in width it sometimes extends to half a mile, its depth varying from 50 feet to as many fathoms. The Victoria debouches into Cambridge Gulf, 14° 14′ S. lat. and 129° 30′ E. long., an estuary 20 miles broad, with a depth of 8 or 10 fathoms. To the westward of this district run two other large rivers, the Prince Regent and the Glenelg, the latter being navigable, with a fertile country on its banks. The Roper, a navigable stream in Arnhem Land, has a width of 500 to 800 yards 40 or 50 miles from its mouth, which is at the Limmen Bight in the Gulf of Carpentaria. In the more settled and inhabited provinces of Australia there are the Brisbane, the Fitzroy, and the Burdekin, rivers of Queensland; the Glenelg River, of Victoria; and the Swan River, of West Australia. But this continent cannot boast of a Nile, an Indus, or a Mississippi, and the interior suffers from the want of water communication.

Geology.—The interior plain of Australia, enclosed by the coast mountain ranges, is a vast concave table of sandstone, with a surface area of 1,500,000 square miles. The sedimentary rock, in some parts, has been washed away or scooped out; but in the opinion of Mr W. H. L. Ranken (*Dominion of Australia*, 1874), the edges of the plateau, where highest and least reduced by denudation, are actually formed of this sediment. While the southern margin of the plain consists of walls of sandstone cliffs, extending along the sea-coast, the plateau on the east, south-east, the west, and partly on the north, is bordered by terraced ramparts of mountains. These elevations consist of granite and syenite on the west side, rising from 1000 to 3000 feet in height. On the east side, in New South Wales and Gipps' Land, they rise to a much greater height, attaining 7000 feet at the south-east corner in the Australian Alps. Here, too, the sandstone masses are often violently rent asunder, and mingled with the overflows of igneous matter, forming basalt and trap. On the north side of the continent, except around the Gulf of Carpentaria, the edge of the sandstone table-land has a great elevation; it is cut by the Alligator River into gorges 3800 feet deep.

In examining more particularly the geological structure of eastern Australia, we must take into account the neighbouring island of Tasmania. The late Count Strzelecki, author of the first scientific essay upon the subject, in 1845, after minutely describing all the mountain ranges of

New South Wales, passes on to Wilson Promontory, the most southerly point of Australia, whence he looks seaward at the islands in Bass's Strait. As he there observes the Tasmanian mountains, with which he is equally familiar, it occurs to him that the whole is the result of identical forces, operating in a direction from north-east to south-west. Such phenomena he ascribes to a series of "volcanoes of elevation," along a vast fissure of the earth, upon the line regarded by him as "the Australian eastern axis of perturbation." These forces he believes to have been exerted, with different degrees of intensity, at four several epochs, which are indicated by the character of the sedimentary rocks, broken through or contorted by the eruptive greenstone and basalt. That eruptive action is seen in the ravines and precipices of the Blue Mountains near Sydney; in the Grose valley, below Mount Hay and its neighbours, Mount King George and Mount Tomah; but still more remarkably in the mountains of Tasmania, viewed from Ben Lomond, within 30 miles of Launceston. The sedimentary deposits of the first epoch are characterised by the presence of mica slate, and of argillaceous and siliceous slate, as well as by the absence of gneiss. Those of the second epoch are found to be arenaceous, calcareous, or argillaceous stratified deposits. The third epoch includes the coal deposits, with their intervening shales and sandstones, including many fossils; while the fourth and last epoch is marked by the occurrence of elevated peaks, and by the remains of land animals found in the limestone caves or in alluvial deposits.

The Rev. W. B. Clarke, of Sydney, again, in a revised treatise published in 1871, expresses a doubt whether the southern range of mountains, extending to Wilson's Promontory, be really a continuation of the main Cordillera of New South Wales. He rather considers this to be prolonged in a westerly direction, taking a bend that way at the Warragong or Snowy Alps, and to be continued within 60 miles of the border of South Australia, which is on the 141st meridian of E. long. The subject is further discussed by Mr R. Brough Smith, of Melbourne, in his essay of 1872 on the mineralogy and rock formations of Victoria. This geologist has also remarked that the Murray, which must have repeatedly shifted its bed and changed its outlet, may have once been a far more powerful stream, flooding a vast tract of the interior, and thus becoming an effective agent in the geological formations of all south-east Australia. It has produced, in Victoria more especially, the Tertiary stratifications which are equivalent to the Pliocene rocks of Europe.

Throughout the whole of eastern Australia, including New South Wales and Queensland, while no tertiary *marine* deposits have been found, there occur many remarkable beds of siliceous sandstone, bearing impressions of ferns and leaves of trees, which are referred to the Tertiary epoch.

An interesting theory is advanced by Mr Clarke to account for the absence of Tertiary deposits on the eastern coast, when they are found on the western and southern coasts of Australia. In the islands of New Caledonia and other Australasian groups, from the Louisiade, near New Guinea, to New Zealand, there is a repetition of Australian geological formations, and there are abundant Tertiary deposits; and this may confirm the supposition that the Australian continent at some period extended farther to the east, and that a vast portion has disappeared under the ocean. To the same hypothetical cause Mr Darwin ascribes the formation of the Great Barrier Reef, stretching along the east coast from S. lat. 22° 23′ to Torres Strait, with an interval between it and the land varying from 12 to 140 miles.

With regard to the more remote geological epochs, Australia presents fewer materials for study than the other continents of our globe. Mr Clarke doubts the origin of some of the more ancient slates mentioned in the "first epoch" of Count Strzelecki, and does not find, either in eastern or in southern Australia, sufficient proof that these regions contain azoic and metamorphic rocks. Large masses of granite occur along the coast, and more extensively in Western Australia. Of the lower Palæozoic there is a great deal of Upper Silurian rock in New South Wales and Queensland, and some in Tasmania. It is in the Lower Silurian formation, as Sir Roderick Murchison predicted, that gold deposits are chiefly found. Rocks of the Devonian period are not yet proved to exist anywhere in Australia, and it is doubtful if any true Permian or Trias, so common elsewhere, have been met with in this continent. The great Carboniferous series is very prominent in New South Wales and in parts of Queensland; it prevails less in Victoria. Coal-beds, of thickness varying from 3 feet to 30 feet, are found associated, both above and below, with fossils resembling those of the Carboniferous strata in Ireland. Their antiquity is proved beyond question, in some districts, as in the valley of the Hawkesbury, where they are overlaid with beds of sandstone, shale, and conglomerate, 1000 feet thick. It has been shown by Mr Daintree that there is a very extensive distribution of the Secondary or Mesozoic rocks in Queensland—the Cretaceous strata, both there and in Western Australia, covering a large area. The Oolitic are more abundant in Western Australia.

The great plains of the interior, and the slopes of the inner mountain ranges, consist largely of deposits of the Tertiary epoch. They occupy an immense area in Victoria and New South Wales, including the Riverina district, which was probably, as Mr Brough Smith considers, levelled and planed down by the ancient vast expansion of the Murray. "The waves of the sea," he remarks, "and the waters of this river, have eaten away mountains of granite and great hills of schist in past times, and placed instead of them a smooth covering of sands and clays." The great basin east of Port Phillip, connected with another basin about Westernport, is underlaid with Mesozoic carbonaceous rocks, upper Miocene, a nodular basalt, and decomposed amygdaloid of older volcanic origin, the quartzose drift of the first Pliocene formations, and some volcanic products of more recent date. Here the Miocene beds abound with fossil leaves of plants belonging to that age. The sands, clays, and gravels of later periods, in the ancient beds of the streams within the Silurian areas, are more or less auriferous. Some of the deeper "leads" of the gold-miner contain fossil fruits and the trunks and branches of trees, which are described by Baron von Müller in the Melbourne official reports of the mining surveyors. In the Ballarat gold-fields the auriferous quartzose gravels are overlaid by flows of lava and vesicular volcanic rocks, while in a neighbouring district south of Ballarat, pebbles and sand are cemented by ferruginous matter into an extremely hard conglomerate.

In eastern Australia, where no Tertiary marine deposits are met with, there are deep accumulations of drift, such as transmuted beds of the Carboniferous formation, porphyry, and basalt, and other igneous rocks, and fragments of the older Palæozoic strata. Many of the drift streams are not only highly auriferous, but contain gems of all kinds. Diamonds, though of small size, have been taken from the Cudgegong River, near Mudgee, in New South Wales, and likewise from the Macquarie River.

In the eastern plains of the interior, embedded in black muddy trappean soil, are found the bones of enormous animals of the marsupial or kangaroo order, as well as birds, fishes, and reptiles. The accumulations of bones in caverns at Wellington, New South Wales, and on the rivers Colo, Macleay, and Coodradigbee, are of great interest.

A femur bone of the dinornis, the gigantic extinct bird of New Zealand, has been discovered in the drift on Peak Downs in eastern Australia, at the depth of 188 feet; and this would lead to the belief that land once existed where now the Pacific Ocean separates by a thousand miles two countries of Australasia, whose present animal and vegetable races have so little in common.

Minerals.—The useful and precious metals exist in considerable quantities in each of the five provinces of Australia. New South Wales has abundance of gold, copper, iron, and coal, as well as silver, lead, and tin. The mineral riches of Victoria, though almost confined to gold, have been the main cause of her rapid progress. South Australia possesses the most valuable copper mines. Queensland ranks next to the last-named province for copper, and excels her neighbours in the production of tin, while gold, iron, and coal are also found in considerable quantities. In Western Australia mines of lead, silver, and copper have been opened; and there is much ironstone.

The discovery of gold in New South Wales and Victoria took place in 1851, and during the next twenty years Victoria exported 40,750,000 oz. of the precious metal, while New South Wales, from 1851 to 1871, exported nearly 10,000,000 ounces. The Queensland gold mines, since 1860, have displayed increasing promise; up to the end of 1872 they had yielded rather less than 1,000,000 ounces; but much was expected, at a more recent date, from the Palmer River and other districts of the north. The yearly value of the aggregate gold exports of Australia, on the average of fifteen years, has been £10,000,000. Victoria alone has produced gold to the value of £170,000,000. The alluvial gold-fields, in which the early diggers, with the simplest tools, obtained for a short time large quantities of the coveted ore, seem now to be mostly exhausted. It is in the quartz formations of the mountain ranges, or in those at a great depth underground, reached by the sinking of shafts and regular mining operations, that Australian gold is henceforth to be chiefly procured. There are mines in Victoria 1000 feet deep, as at Clunes, and many others from 300 to 600 feet.

The copper mines of Burra Burra, in South Australia, proved very profitable some twenty-five years ago, yielding in a twelvemonth ore to the value of £350,000, and the Moonta mines, in 1872, were scarcely less productive. The province of South Australia, in that year, exported copper to the amount of £800,000. Queensland, in 1873, produced one-fourth that quantity. Tin, an article of great mercantile interest, is divided between Queensland and New South Wales in a frontier district, two-thirds of the extent of which belongs to the Darling Downs, within the last-mentioned province. There is a little tin, also, in some parts of Victoria. Lead, silver, and cinnabar have been obtained not only in New South Wales, but likewise in Western Australia.

The abundance of good iron ore, in convenient vicinity to thick beds of excellent coal, ensures a future career of manufacturing prosperity to New South Wales, and not less to Queensland. The country north and south of Sydney, and west of that city 100 miles inland to the dividing range of mountains, is all of Carboniferous formation. At the mouth of the Hunter River, from the port and town of Newcastle, coal was exported in 1873 to the value of £1,000,000 sterling. The collieries there taken up have an extent of 35,000 acres, but the area of the coal-field is officially estimated at 10,000,000 acres, and the seams are 9 feet to 11 feet thick. The quality of this coal is said to be equal to that of Great Britain for most furnace purposes, and it is generally used by steamships in the Pacific and Chinese navigation. Next in importance are the Wollongong collieries, south of Sydney, and those of Hartley, Maitland, and Berrima, now connected by railway with the capital.

In each of the places above named there is iron of a superior quality, the working of which to advantage cannot be long delayed. On the Illawarra coast it is found close to the finest bituminous coal, and to limestone. The iron of New South Wales is mostly hæmatite, and the ironstone contains from 60 to 70 per cent. of ore.

Among other mineral products of the same region are cannel coal and shale yielding kerosene oil. This is a recognised article of export from New South Wales to the other colonies. It is hardly worth while to speak of diamonds, opals, and precious stones, but they are often picked up, though of small size, along the Mudgee and Abercrombie Rivers, and at Beechworth and Daylesford, in Victoria.

Climate.—The Australian continent, extending over 28° of latitude, might be expected to show a considerable diversity of climate. In reality, however, it experiences fewer climatic variations than the other great continents, owing to its distance (28°) from the Antarctic circle and (11°) from the equator. There is, besides, a powerful determining cause in the uniform character and undivided extent of its dry interior plain. On this subject Mr Ranken, in his *Dominion of Australia*, remarks—"A basin having its northern portion in the tropics, it acts like an oven under the daily sun. It becomes daily heated; then its atmosphere expands; but such is its immensity that no sufficient supply of moist sea air from the neighbouring oceans can reach it, to supply the vacancy caused by this expansion. Of an almost perfectly flat surface, there is no play for currents of air upon it; only the heat is daily absorbed and nightly radiated. Such is the heat, that in the summer the soil is more like a fire than an oven; the air, if it moves, is like a furnace-blast; and such its extent and sameness, that as great heat may prevail hundreds of miles south as north of the tropics." This continual radiation of heat is sometimes relieved—though not with the regularity of an annual season, indeed rather at uncertain intervals of several years—by the admission of masses of vapour, drawn in from the Pacific or the Indian Ocean. Great masses of clouds, after labouring many months to reach the interior from the sea, succeed in passing over the sea-bound mountains, and spread themselves in floods of rain upon the inland country. The north-west shore, and that of Carpentaria, are favoured with an annual visitation of the monsoons, from December to March, penetrating as far as 500 miles into the continent, where the sands of the desert are driven in wavy heaps by the force of this wind. But South Australia, though it feels a cool sea breeze from the south-west, gets little rain, for lack of any mountain range parallel with the coast to arrest and condense the passing vapours. The yearly rainfall at Adelaide and Gawler is therefore not more than 15 or 20 inches, while at the head of Spencer Gulf it is but 6 or 8. In Victoria and in New South Wales, on the contrary, where a wall of mountain fronts the ocean, most places on the sea-board enjoy a fair allowance of rain. It is 32 inches at Portland, nearly 26 inches at Melbourne; at Sydney and Newcastle, on the east coast, as much as 48 and 44 inches in the year. But at Brisbane, in Queensland, farther north, it amounts to 50 inches; at Rockingham Bay, in latitude 18° S., where the hills are covered with dense forests, the rainfall in 1871 was no less than 90 inches. In every part, however, of this magnificent highland region, the supply of moisture is rapidly diminished by passing inland; so that very little remains to fall on the interior or western slopes of the coast ranges, and to irrigate the interior plains.

With regard to the temperature, the northern regions of the continent being situated within the tropic of Capricorn,

resemble the parts of South America and South Africa, that are situated in corresponding latitudes. The seaward districts of New South Wales seem in this respect to be like Southern Europe. The mean annual temperature of Sydney is 62° 4′ Fahr., almost equal to that of Lisbon in Portugal. The inland plains of this colony, however, west of the Blue Mountains, which suffer much from evaporation, experience in summer a heat which rises to 100° Fahr. in the shade, and sometimes as high as 140°. There are highland districts, on the contrary, such as Kiandra, 4640 feet above the sea-level, where frost, snow, and hail are endured through the winter. On the Australian Alps, cold being more intense in the dry air, the limit of perpetual snow comes down to 7145 feet. The days on which rain falls in the coast regions of New South Wales average from 100 to 150 in the year, and the amount from 20 inches to 50 inches, decreasing generally farther inland.

In winter, in New South Wales, the prevalent winds blow from the west, with occasional storms of wind and rain from the eastward; while the autumn months have much cloudy weather, not accompanied by rain. January and February are the hottest months of summer, and July the coldest month of winter.

With regard to the climate of Victoria, Mr Robert Ellery, Government astronomer at Melbourne, in his report of 1872, furnishes exact information. The mean annual temperature at Melbourne during fourteen years was 57°·6, and that of the whole province 56°·8, including stations 2000 feet or 1400 feet above the sea-level at Daylesford and Ballarat. This is equivalent to the mean annual temperature of Marseilles and Florence, in the northern hemisphere, but the climate of Melbourne is much more equable than that of the Mediterranean shores. The lowest temperature yet recorded has been 27°, or 5° below the freezing point; the highest, 111° in the shade, occurring during one of the hot winds, called "brickfielders," which, loaded with dust, occasionally blow for a few hours in summer. At Sandhurst, 778 feet above the sea, the greatest extremes of temperature yet observed were 117° and 27°·5; at Ballarat the extreme of winter cold was 10° below freezing.

The amount of humidity in the air is liable to great and rapid variations in the summer months. It is sometimes reduced as much as 60 per cent. within a few hours, by the effect of hot dry winds. But this is compensated by an access of moisture upon a change of wind. The annual average rainfall at Melbourne, which for thirty years is stated at 25·66 inches, does not seem less than that of places in similar latitudes in other parts of the world. Yet it proves inadequate, because of the great amount of evaporation, estimated by Professor Neumayer at 42 inches.

The spring season in Victoria, consisting of the months of September, October, and November, is genial and pleasant, with some rain. The summer—December, January, and February—is generally hot and dry, though its first month is sometimes broken by storms of cold wind and heavy rain. In February the north winds assume the character of siroccos, and bush-fires often devastate the grassy plains and forests of the inland country. The autumn months—March, April, and May—are, in general, the most agreeable; and at this season vegetable life is refreshed, and puts forth a growth equal to that of the spring. The winter is June, July, and August, with strong, dry, cold winds from the north, alternating with frequent rain from the opposite quarter; there is little ice or snow, except in the mountain districts.

Botany.—A probable computation of the whole number of distinct vegetable species indigenous to Australia and Tasmania has been made by Baron Ferdinand von Müller, the Government botanist at Melbourne. He believes that, omitting the minute fungi, there will not be found above 10,000 species of Australian plants. The standard authority upon this subject, so far as it could be known sixty years ago, but now requiring to be completed and extended, was the *Prodromus Floræ Novæ Hollandiæ*, published in 1810 by Mr Robert Brown of the British Museum. Besides making personal observations from 1802 to 1805, he had classified the collections procured by Sir Joseph Banks when Captain Cook's ship visited the eastern shore. Upon that occasion, in 1769, the name of Botany Bay was given to an inlet near Port Jackson, from the variety of new specimens found there. Baron von Müller's Report of 1857 on the researches made by him alone in the North Australian exploring expedition under Mr Gregory, exhibits 2000 new species, representing more than 800 genera, which belong to 160 different orders. He could discover no new natural order, or fundamental form of the vegetable kingdom, in a minute examination of the flora of Arnhem Land, the country around the Gulf of Carpentaria, and the Victoria River, but 60 genera were found that had not been noticed by any earlier Australian botanist.

The eastern parts of this continent, New South Wales and Queensland, are very much richer, both in their botany and in their zoology, than any other parts of Australia. Much was done here for the former science, half a century ago, by Mr Allan Cunningham, whose monumental obelisk fitly stands in the Botanic Garden at Sydney. In general, the growth of trees on the north and north-west coasts is wanting in size and regularity, compared with their growth in eastern Australia. To the last-mentioned region, for instance, the pines are entirely confined; here the Moreton Bay pine, and Bunya Bunya pine, of the genus *Araucaria*, growing to 150 feet in height, yield excellent timber. The red cedar, the iron bark, the blue gum-tree, and others useful to the carpenter, belong likewise to the eastern highlands. The *Casuarina*, or she-oak, is found on the shores of Carpentaria and in the interior, but not on the banks of the Victoria River to the north-west. Of the *Eucalyptus*, or gum-tree, Australia has 400 species; but the one most uniformly distributed is the *Eucalyptus rostrata* or *acuminata*, called the flooded gum-tree; its timber is durable, and takes a fine polish. Rosewood, tulip-wood, sandal-wood, and satin-wood, with other materials for the cabinetmaker's ornamental work, abound in the forests of Queensland. The forest scenery of the more northerly districts, within the tropics, and onwards to Rockingham Bay, is described as of great luxuriance. It consists of many kinds of large umbrageous trees, some of an Indian type, intermixed with noble araucarias, all matted together in an impervious thicket by lianes of the convolvulus, the calamus, and other plants, climbing or pendent, harbouring in their shade many parasitical orchids and ferns. Such forests overhang the seaward sides of the mountain ranges, where they inhale abundant moisture from the winds of the Pacific Ocean, and feed upon a congenial soil from the decomposition of schistose rocks.

A striking contrast is offered to the view beyond the coast ranges. The interior of Queensland presents either highland downs of basaltic origin, almost bare of trees, but with abundant herbaceous vegetation, good pasture grass, and an immense quantity of vervain, or the Brigalow scrub, merely shrubs and small trees, on a soil of argillaceous sandstone. The sandstone table-lands, again, naked and dry, produce but a few diminutive eucalypti, and sparse tufts of uneatable grasses, while the inland deserts have only the acacia to break the monotony of the scene. The character of the inland flora adds confirmation to the belief that the interior was formerly a marine soil, which

has not yet been deprived of its saline properties. In the districts farthest removed from the action of fresh water, hundreds of miles are covered with such plants as will grow on the sea-shore, *e.g.*, the mesembryanthemum called pig's face or Hottentot fig. Other species belonging to the coastward uplands seem to have been conveyed into the interior by the action of water, as the belts of timber, and of pine or cypress scrub, are always found to extend along the line of direction taken by floods. They grow on sandy ridges, alongside of hollows, or depressed channels. On the north coast, so much of which is flat, and often swampy or sandy, the mangrove flourishes as in other tropical regions.

From the extreme aridity of the climate in most parts of northern Australia, there is a singular absence of mosses and lichens. North-west Australia possesses, in the *Adansonia Gregorii*, or gouty-stem tree, a counterpart of the West African baobab, or monkey-bread tree. It is worthy of remark that, with a few exceptions, the Australian trees are evergreens. They also show a peculiar reverted position of their leaves, which hang vertically, turning their edges instead of their sides towards the sun; and the eucalypti have the peculiarity of shedding their bark annually instead of their leaves. In Australia the native species of lily, tulip, and honeysuckle appear as standard trees of considerable size. The native grasses do not form a continuous and even greensward, as in Europe, but grow in detached clumps or tufts. None of the cereal plants are indigenous, and very few of the fruits or roots that supply human food; but many Australian plants are likely to be valuable for medicinal or chemical manufactures.

This continent, as might be expected, has some of the same botanical families that occupy South Africa, Polynesia, and South America. Its relations in that respect to Europe are shown by Alphonse de Candolle's tabular statements in the *Géographie Botanique Raisonnée.* He gives the exact number of species common to Australia and to France in each of the principal families or natural orders. It appears that of 3614 species of phanerogamic plants in France, only 45 belong to Australia. But it will be sufficient, without citing the numerical details, to quote Baron von Müller's list of the natural orders having the most numerous species of indigenous growth in South Australia. They are here arranged in succession, according to their comparative amounts of specific diversity, those which have the greatest number of species being mentioned first. Of the phanerogamic series, the leguminous and the composite families united form nearly one-fourth. Indeed, the half of the dicotyledonous plants, or exogens, that exist in the sub-tropical districts belong to these two orders. Next come the myrtaceous plants, the ferns, and the grasses; the Proteaceæ, which form a conspicuous feature of Australian botany; the Orchidaceæ, the epacrid family, and the parsley family, or Umbelliferæ; the Diosmeæ, a sub-order of the Rutaceæ or rue family; the Liliaceæ, the Labiatæ or mint family, the Goodeniæ, the Scrophulariaceæ or figworts, and the Salsolaceæ. The Ranunculaceæ, the geranium family, the rosaceous plants, and the epacrid group, are not found in Australia north of the tropical line.

Animals.—The zoology of Australia and Tasmania presents a very conspicuous point of difference from that of other regions of the globe, in the prevalence of non-placental mammalia. The vast majority of the mammalia are provided with an organ in the uterus, by which, before the birth of their young, a vascular connection is maintained between the embryo and the parent animal. There are two orders, the Marsupialia and the Monotremata, which do not possess this organ. Both these are found in Australia, to which region indeed they are not absolutely confined; but the marsupials alone constitute two-thirds of all the Australian species of mammals. It is the well-known peculiarity of this order that the female has a pouch or fold of skin upon her abdomen, in which she can place the young for suckling within reach of her teats. The opossum of America is the only species out of Australasia which is thus provided. Australia is inhabited by at least 110 different species of marsupials, which have been arranged in five tribes, according to the food they eat, viz., the root-eaters (wombats), the fruit-eaters (phalangers), the grass-eaters (kangaroos), the insect-eaters (bandicoots), and the flesh-eaters (native cats and rats). Of these tribes the wombats are closely allied to the phalangers, represented by the opossums and flying squirrels, with the native bear, while fossil remains of twenty extinct species have also been found. Of wombats now existing there are four species, all of nearly the same size, seldom exceeding 100 ℔ in weight. They all burrow in the ground, and their habitat is in New South Wales, Tasmania, and South Australia. There is but one species of the singular animal miscalled the native bear, which is more like a sloth in its habits. Three varieties of brush-tailed opossum are found, but one of them exists only in Tasmania; and there are three ring-tailed varieties in almost every part of Australia. The great flying phalanger (Petaurista) is nearly allied to the last-mentioned genus; it exists only in East Australia; as does the small flying phalanger (Belideus), which is restricted to mountain districts. The interior of Australia and the west coast are wanting in these species, but two or three of them occur on the north coast. The smallest phalanger (*Acrobata pygmæa*) is less than a mouse, and has a feathery tail. The little *Tarsipes rostratus* is almost toothless, but has a long hairy tongue, which it thrusts into flowers to suck their sweetness.

The kangaroo (Macropus) and most of its congeners show an extraordinary disproportion of the hind limbs to the fore part of the body. The rock wallabies again have short tarsi of the hind legs, with a long pliable tail for climbing, like that of the tree kangaroo of New Guinea, or that of the jerboa. Of the larger kangaroos, which attain a weight of 200 ℔ and more, eight species are named, only one of which is found in West Australia. There are some twenty smaller species in Australia and Tasmania, besides the rock wallabies and the hare kangaroos; these last are wonderfully swift, making clear jumps eight or ten feet high. To this agility they owe their preservation from the prairie fires, which are so destructive in the interior during seasons of drought. In the rat kangaroo there is not the same disproportion of the limbs; it approaches more nearly to the bandicoot, of which seven species exist, from the size of a rat to that of a rabbit. The carnivorous tribe of marsupials, the larger species at any rate, belong more to Tasmania, which has its "tiger" and its "devil." But the native cat, or dasyurus, is common to every part of Australia. Several different species of pouched rats and mice, one or two living in trees, are reckoned among the flesh-eaters. Fossil bones of extinct kangaroo species are met with, which must have been of enormous size, twice or thrice that of any species now living.

We pass on to the other curious order of non-placental mammals, that of the Monotremata, so called from the structure of their organs of evacuation with a single orifice, as in birds. Their abdominal bones are like those of the marsupials; and they are furnished with pouches for their young, but have no teats, the milk being distilled into their pouches from the mammary glands. Australia and Tasmania possess two animals of this order,—the echidna, or spiny ant-eater (hairy in Tasmania), and the *Platypus anatinus*, the duck-billed water-mole, otherwise named the *Ornithorhynchus paradoxus*. This odd animal is provided

with a bill or beak, which is not, like that of a bird, affixed to the skeleton, but is merely attached to the skin and muscles.

Australia has no apes, monkeys, or baboons, and no ruminant beasts. The comparatively few indigenous placental mammals, besides the dingo, or wild dog—which, however, may have come from the islands north of this continent—are of the bat tribe and of the rodent or rat tribe. There are four species of large fruit-eating bats, called flying foxes, twenty of insect-eating bats, above twenty of land-rats, and five of water-rats. The sea produces three different seals, which often ascend rivers from the coast, and can live in lagoons of fresh water; many cetaceans, besides the "right whale" and sperm whale; and the dugong, found on the northern shores, which yields a valuable medicinal oil.

The birds of Australia in their number and variety of species (reckoned at 690) may be deemed some compensation for its poverty of mammals; yet it will not stand comparison in this respect with regions of Africa and South America in the same latitudes. The black swan of West Australia was thought remarkable when discovered, as belying an old Latin proverb. There is also a white eagle. The vulture is wanting. Sixty species of parrots, some of them very handsome, are found in Australia. The emu, a large bird of the order Cursores, or runners, corresponds with the African and Arabian ostrich, the rhea of South America, and the cassowary of the Moluccas and New Guinea. In New Zealand this order is represented by the apteryx, as it formerly was by the gigantic moa, the remains of which have been found likewise in Queensland. Of the same species as the birds of paradise is the graceful *Mænura superba*, or lyre-bird, with its tail feathers spread in the shape of a lyre. The mound-raising megapodes, the bower-building satin-birds, and several others, display peculiar habits. The honey-eaters present a great diversity of plumage. There are also many kinds of game birds, pigeons, ducks, geese, plovers, and quails.

The ornithology of New South Wales and Queensland is more varied and interesting than that of the other provinces.

As for reptiles, Australia has a few tortoises, all of one family, and not of great size. The "leathery turtle," which is herbivorous, and yields abundance of oil, has been caught at sea off the Illawarra coast so large as 9 feet in length. The saurians or lizards are numerous, chiefly on dry sandy or rocky ground in the tropical region. The great crocodile of Queensland is 30 feet long; there is a smaller one, 6 feet long, to be met with in the shallow lagoons of the interior. The monitor, or fork-tongued lizard, which burrows in the earth, climbs, and swims, is said to grow to a length of 8 or 9 feet. This species, and many others, do not extend to Tasmania. There are about twenty kinds of night-lizards, and many which hibernate. One species can utter a cry when pained or alarmed, and the tall-standing frilled lizard can lift its forelegs, and squat or hop like a kangaroo. There is also the *Moloch horridus* of South and West Australia, covered with tubercles bearing large spines, which give it a very strange aspect. This and some other lizards have power to change their colour, not only from light to dark, but in some parts from yellow to grey or red. Dr Gray, of the British Museum, has described fifty species of Australian lizard.

The snakes are reckoned at sixty-three species, of which forty-two are venomous, but only five dangerous. North Queensland has many harmless pythons. There are forty or fifty different sorts of frogs; the commonest is distinguished by its blue legs and bronze or gold back; the largest is bright green; while the tree-frog has a loud shrill voice, always heard during rain.

The Australian seas and rivers are inhabited by many fishes of the same genera as exist in the southern parts of Asia and Africa. Of those peculiar to Australian waters may be mentioned the arripis, represented by what is called among the colonists a salmon trout. A very fine fresh-water fish is the Murray cod, which sometimes weighs 100 lb; and the golden perch, found in the same river, has rare beauty of colour. Among the sea-fish, the snapper is of great value as an article of food, and its weight comes up to 50 lb. This is the *Pagrus unicolor*, of the family of Sparidæ, which includes also the bream. Its colours are beautiful, pink and red with a silvery gloss; but the male as it grows old takes on a singular deformity of the head, with a swelling in the shape of a monstrous human-like nose. These fish are caught in numbers outside Port Jackson for the Sydney market. Two species of mackerel, differing somewhat from the European species, are also caught on the coasts. The so-called red garnet, a pretty fish, with hues of carmine and blue stripes on its head, is much esteemed for the table. The *Trigla polyommata*, or flying garnet, is a greater beauty, with its body of crimson and silver, and its large pectoral fins, spread like wings, of a rich green, bordered with purple, and relieved by a black and white spot. Whiting, mullet, gar-fish, rock cod, and many others known by local names, are in the lists of edible fishes belonging to New South Wales and Victoria. Much interesting and valuable information upon Australian zoology will be found in a recent essay by Mr Gerard Krefft, curator and secretary of the museum at Sydney, and in the Count de Castelnau's report on the fishes of Victoria at the International Exhibition of 1873.

Aborigines.—The Papuan, Melanesian, or Australasian aborigines exhibit certain peculiarities which are not found in the African negro, to which race they otherwise present some similarity. In the Australasian the forehead is higher, the under jaw less projecting, the nose, though flat and extended compared with that of the European, is less depressed than in the African. His lips are thick, but not protuberant; and the eyes are sunken, large, and black. The colour of his skin is lighter—of a dusky hue—than that of the Negro. In stature he equals the average European, but tall men are rare, except in North Queensland; his body and limbs are well shaped, strongly jointed, and highly muscular. The hind parts are not, as in the African, excessively raised; and while the calf of the leg is deficient, the heel is straight. The natives of Papua have woolly spirally-twisted hair. Those of Tasmania, now exterminated, had the same peculiarity. But the natives of the Australian continent have straight or curly black hair. The men wear short beards and whiskers.

Their mental faculties, though probably inferior to those of the Polynesian copper-coloured race, are not contemptible. They have much acuteness of perception for the relations of individual objects, but little power of generalisation. No word exists in their language for the general terms tree, bird, or fish; yet they have invented a name for every species of vegetable and animal they know. The grammatical structure of some North Australian languages has a considerable degree of refinement. The verb presents a variety of conjugations, expressing nearly all the moods and tenses of the Greek. There is a dual, as well as a plural form in the declension of verbs, nouns, pronouns, and adjectives. The distinction of genders is not marked, except in proper names of men and women. All parts of speech, except adverbs, are declined by terminational inflections. There are words for the elementary numbers, one, two, three; but "four" is usually expressed by "two-two;" then "five" by "two-three," and so on. They have no idea of decimals. The number and diversity of separate languages, not mere dialects, is truly bewildering. Tribes of a few hundred people, living within a few

miles of each other, have often scarcely a phrase in common. This is more especially observed in New South Wales, a country much intersected by dividing mountain ranges. But one language is spoken all along the Rivers Murray and Darling, while the next neighbours of the Murray tribes, on both sides, are unable to converse with them.

It is, nevertheless, tolerably certain that all the natives of Australia belong to one stock. There appears reason to believe that their progenitors originally landed on the north-west coast, that of Cambridge Gulf or Arnhem Land, in canoes drifting from the island of Timor. They seem then to have advanced over the continent in three separate directions. By one route they moved, in the course of ages, directly across to the south coast, near the head of the Great Bight, Spencer Gulf, and the Gulf of St Vincent. Another division followed the west coast to Swan River, and round by King George's Sound. The third and most important body, turning eastward, crossed the head of the Gulf of Carpentaria, then split and subdivided itself amidst the rivers and highland ranges of Queensland, while some of its tribes crossing the Upper Darling occupied New South Wales, overspread the Riverina, and peopled the south-eastern quarter of Australia. The proofs and arguments upon which this hypothetical distribution is based are set forth by Mr Eyre in his interesting essay on the Australian aborigines (*Discoveries in Central Australia*, &c., by E. J. Eyre, resident magistrate, Murray River, vol. ii.). It is chiefly the prevalence of some peculiar customs, such as circumcision, or the removal of two upper-jaw teeth at a stated age of adolescence, that seems to mark the common descent of tribes, now widely distant in location, which appear to have belonged to one of the supposed main streams of population. The discontinuance of such customs among the tribes of the other main divisions is plausibly ascribed to local influences. From a comparison of their languages, the diversities of which have been already referred to, it appears that little aid is to be expected from them in ethnological grouping.

The natives of the north-eastern quarter—a tropical region of diversified surface, with many rivers and thick forests, as well as open highlands—are far superior in body, mind, and social habits to those of the rest of Australia. They bear, in fact, most resemblance to their neighbours and kindred in the island of New Guinea, but are still below these in many important respects.

If a general view be taken of the tribes of Australia, and the state in which they existed independently of recent European intercourse, two or three extraordinary defects exhibit themselves. They never, in any situation, cultivated the soil for any kind of food-crop. They never reared any kind of cattle, or kept any domesticated animal except the dog, which probably came over with them in their canoes. They have nowhere built permanent dwellings, but contented themselves with mere hovels for temporary shelter. They have neither manufactured nor possessed any chattels beyond such articles of clothing, weapons, ornaments, and utensils as they might carry on their persons, or in the family store-bag for daily use. Their want of ingenuity and contrivance has, however, undoubtedly been promoted by the natural poverty of the land in which the race settled.

The sole dress of both sexes in their aboriginal state is a cloak of skin or matting, fastened with a skewer, but open on the right-hand side. No headgear is worn, except sometimes a net to confine the hair, a bunch of feathers, or the tails of small animals. The bosom or back is usually tattooed, or rather scored with rows of hideous raised scars, produced by deep gashes at the age when youth comes to manhood or womanhood. Their dwellings, for the most part, are either bowers, formed of the branches of trees, or hovels of piled logs, loosely covered with grass or bark, which they can erect in an hour, wherever they encamp. But some huts of a more commodious and substantial form were seen by Flinders on the south-east coast in 1799, and by Captain King and Sir J. Mitchell on the north-east, where they no longer appear. The ingenuity of the race is mostly to be recognised in the manufacture of their weapons of warfare and the chase. While the use of the bow and arrow does not seem to have occurred to them, the spear and axe are in general use, commonly made of hard-wood; the hatchets of stone, and the javelins pointed with stone or bone. The peculiar weapon of the Australian is the boomerang, a curved blade of wood, of such remarkable construction, that it swerves from its direct course, sometimes returning so as to hit an object behind the thrower. Their nets, made by women, either of the tendons of animals or the fibres of plants, will catch and hold the strong kangaroo or the emu, or the very large fish of Australian rivers. Canoes of bent bark, for the inland waters, are hastily prepared at need; but the inlets and straits of the north-eastern sea-coast are navigated by larger canoes and rafts of a better construction.

Without claiming permanent ownership of the land, each native tribe was accustomed, till the English squatter came, to enjoy the recognised manorial dominion of its own hunting-ground, perhaps ten or twelve miles square. This was subdivided between the chief heads of families. The affairs of a tribe are ruled by a council of the men past middle age who are still in full vigour of mind and body. One may be their president, but they have no hereditary prince. Their most solemn assemblies take place when the youth undergo one or other of the painful ceremonies of initiation into manhood. In every case of death from disease or unknown causes the sorcerers hold a public inquest, and pretend to ask the corpse how it was killed. Such deaths are invariably ascribed to witchcraft practised by a hostile or envious neighbouring tribe. The bodies of the slain in battle are sometimes eaten, or the fat of the kidneys, at least, is extracted for a feast of victory. But cannibalism in Australia is not confined to the flesh of enemies, nor is it generally associated with an insulting triumph. It is rather, like that reported of the ancient Scythians, a rite of funeral observance, in honour of deceased kindred and friends. The reality of this custom is proved by the testimony of trustworthy English witnesses, who have watched the revolting act. The only idea of a god known to be entertained by these people, is that of Buddai, a gigantic old man lying asleep for ages, with his head resting upon his arm, which is deep in the sand. He is expected one day to awake and eat up the world. They have no religion beyond those gloomy dreams. Their notions of duty relate mostly to neighbourly service and social interest; and they are not all thieves or liars, but are capable of many good deeds. The marriage bond is observed by the wife or wives, the penalty of its violation being death. But chastity upon any other account is a virtue beyond the native conception, though a certain delicacy of feeling in matters of sex is not unknown. The deplorable lack of moral restraint has involved this unhappy race in sufferings which may be easily understood, from their contact with the more reckless and vicious representatives of foreign nations.

The numbers of the native Australians are steadily diminishing. A remnant of the race exists in each of the provinces, while a few tribes still wander over the interior. Altogether it is computed that not more than about 80,000 aborigines remain on the continent.

Perhaps the most complete and trustworthy information on the Australian race is to be found in works published some twenty or thirty years ago, before the country

was occupied as it now is by the European settler. Mr Eyre's work above referred to, and Captain (afterwards Sir George) Grey's *Discoveries in North-West and Western Australia,* are authorities that may be relied upon.

Colonial History.—Of the five Australian provinces, that of New South Wales may be reckoned the oldest. It was in 1788, eighteen years after Captain Cook explored the east coast, that Port Jackson was founded as a penal station for criminals from England; and the settlement retained that character, more or less, during the subsequent fifty years, transportation being virtually suspended in 1839. The colony, however, from 1821 had made a fair start in free industrial progress.

By this time, too, several of the other provinces had come into existence. Van Diemen's Land, now called Tasmania, had been occupied as early as 1803. It was an auxiliary penal station under New South Wales, till in 1825 it became a separate province. From this island, ten years later, parties crossed Bass's Straits to Port Phillip, where a new settlement was shortly established, forming till 1851 a part of New South Wales, but now the richer and more populous colony of Victoria. In 1827 and 1829, an English company endeavoured to plant a settlement at the Swan River, and this, added to a small convict station established in 1825 at King George's Sound, constituted Western Australia. On the shores of the Gulf St Vincent, again, from 1835 to 1837, South Australia was created by another joint-stock company, as an experiment in the Wakefield scheme of colonisation.

Such were the political component parts of British Australia up to 1839. The earlier history, therefore, of New South Wales is peculiar to itself. Unlike the other mainland provinces, it was at first held and used chiefly for the reception of British convicts. When that system was abolished, the social conditions of New South Wales, Victoria, and South Australia became more equal. Previous to the gold discoveries of 1851 they may be included, from 1839, in a general summary view.

The first British governors at Sydney, from 1788, ruled with despotic power. They were naval or military officers in command of the garrison, the convicts, and the few free settlers. The duty was performed by such men as Captain Arthur Phillip, Captain Hunter, and others. In the twelve years' rule of General Macquarie, closing with 1821, the colony made a substantial advance. By means of convict labour roads and bridges were constructed, and a route opened into the interior beyond the Blue Mountains. A population of 30,000, three-fourths of them convicts, formed the infant commonwealth, whose attention was soon directed to the profitable trade of rearing fine wool sheep, first commenced by Mr John M'Arthur in 1803.

During the next ten years, 1821–31, Sir Thomas Brisbane and Sir Ralph Darling, two generals of the army, being successively governors, the colony increased, and eventually succeeded in obtaining the advantages of a representative institution, by means of a legislative council. Then came General Sir Richard Bourke, whose wise and liberal administration proved most beneficial. New South Wales became prosperous and attractive to emigrants with capital. Its enterprising ambition was encouraged by taking fresh country north and south. In the latter direction, explored by Mitchell in 1834 and 1836, lay Australia Felix, now Victoria, including the well-watered, thickly-wooded country of Gipps' Land.

This district, then called Port Phillip, in the time of Governor Sir George Gipps, 1838 to 1846, was growing fast into a position claiming independence. Melbourne, which began with a few huts on the banks of the Yarra-Yarra in 1835, was in 1840 a busy town of 6000 inhabitants, the population of the whole district, with the towns of Geelong and Portland, reaching 12,850; while its import trade amounted to £204,000, and its exports to £138,000. Such was the growth of infant Victoria in five years; that of Adelaide or South Australia, in the same period, was nearly equal to it. At Melbourne there was a deputy governor, Mr Latrobe, under Sir George Gipps at Sydney. Adelaide had its own governors, first Captain Hindmarsh, next Colonel Gawler, and then Captain George Grey. Western Australia progressed but slowly, with less than 4000 inhabitants altogether, under Governors Stirling and Hutt.

The general advancement of Australia, to the era of the gold-mining, had been satisfactory, in spite of a severe commercial crisis, from 1841 to 1843, caused by extravagant land speculations and inflated prices. Victoria produced already more wool than New South Wales, the aggregate produce of Australia in 1852 being 45,000,000 lb; and South Australia, between 1842 and this date, had opened most valuable mines of copper. The population of New South Wales in 1851 was 190,000; that of Victoria, 77,000; and that of South Australia about the same.

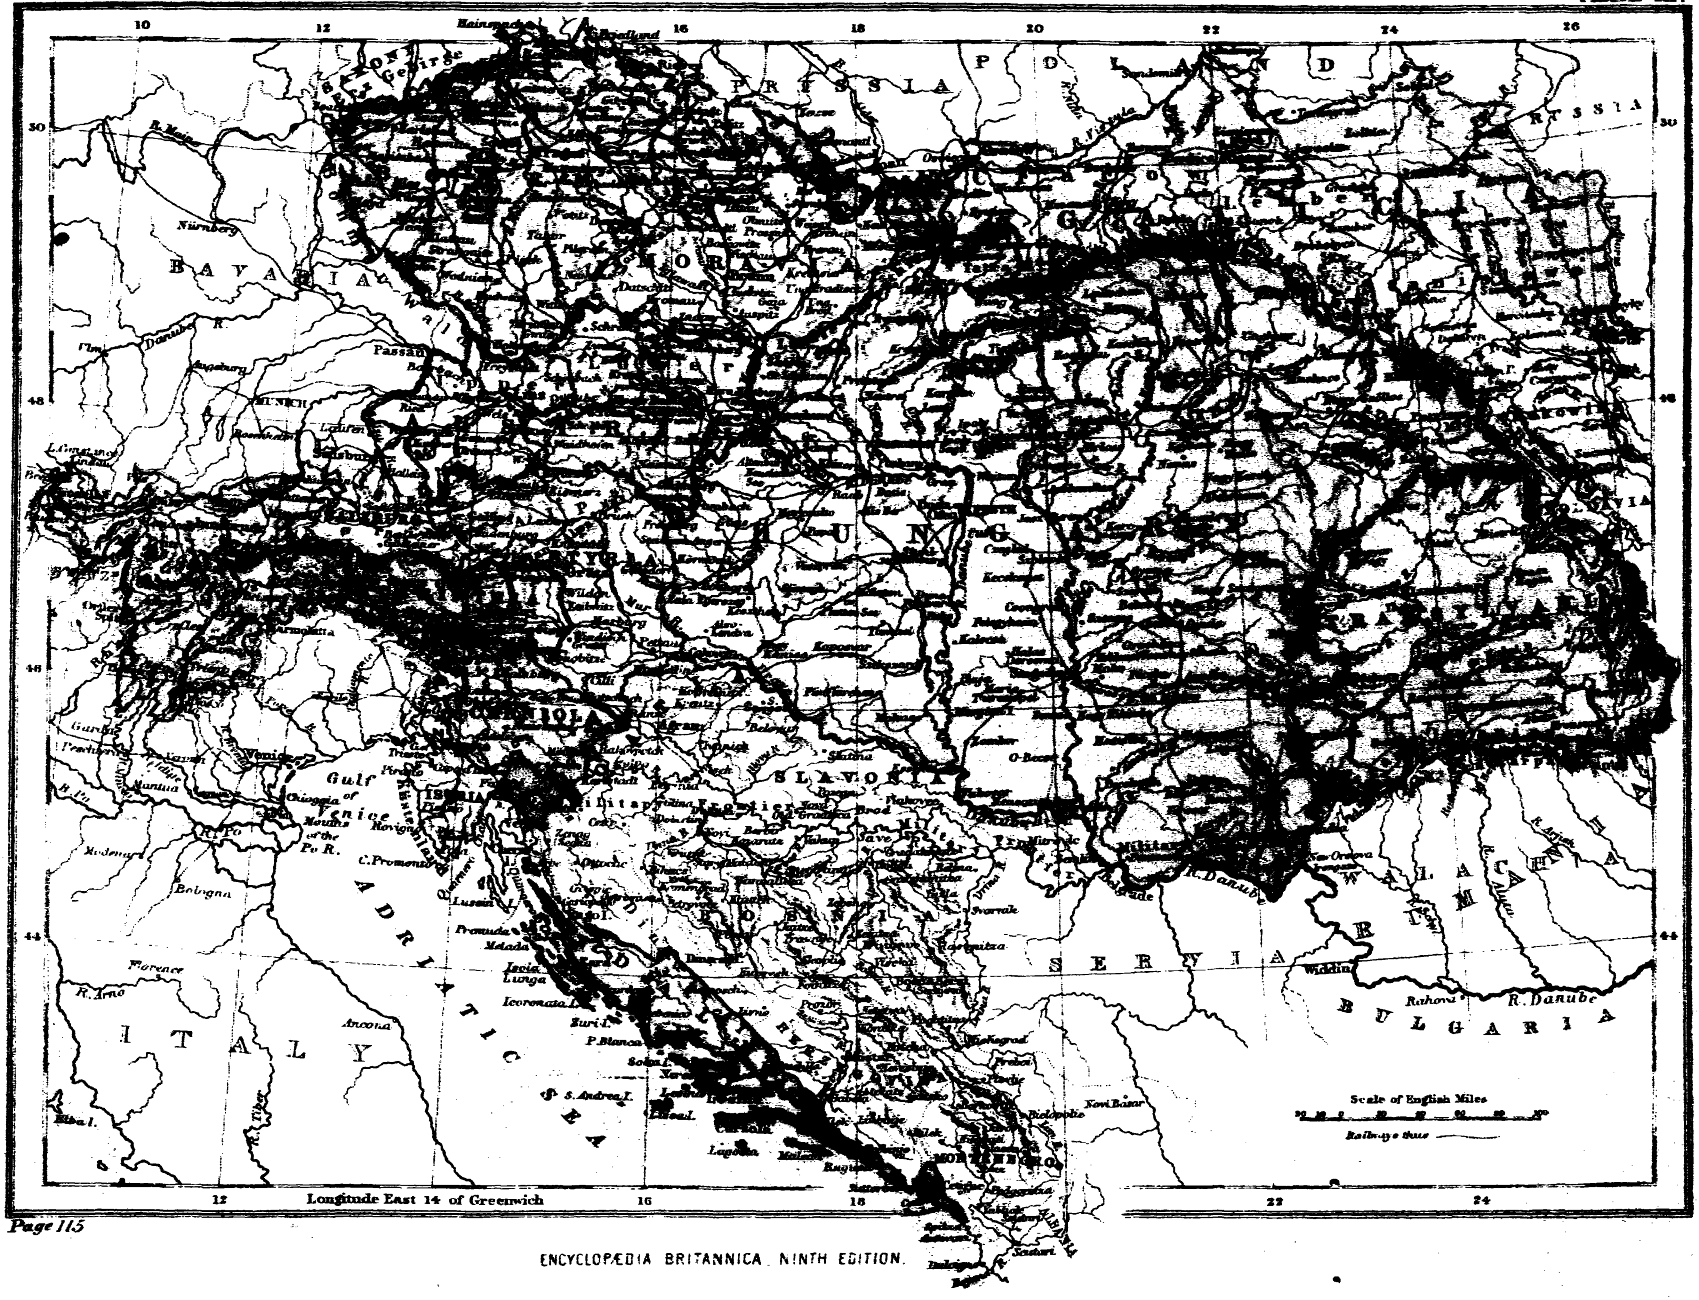
At Summerhill Creek, 20 miles north of Bathurst, in the Macquarie plains, gold was discovered, in February 1851, by Mr E. Hargraves, a gold-miner from California. The intelligence was made known in April or May; and then began a rush of thousands,—men leaving their former employments in the bush or in the towns to search for the ore so greatly coveted in all ages. In August it was found at Anderson's Creek, near Melbourne; a few weeks later the great Ballarat gold-field, 80 miles west of that city, was opened; and after that, Bendigo, now called Sandhurst, to the north. Not only in these lucky provinces, New South Wales and Victoria, where the auriferous deposits were revealed, but in every British colony of Australasia, all ordinary industry was left for the one exciting pursuit. The copper mines of South Australia were for the time deserted, while Tasmania and New Zealand lost many inhabitants, who emigrated to the more promising country. The disturbance of social, industrial, and commercial affairs, during the first two or three years of the gold era, was very great. Immigrants from Europe, and to some extent from North America and China, poured into Melbourne, where the arrivals in 1852 averaged 2000 persons in a week. The population of Victoria was doubled in the first twelvemonth of the gold fever, and the value of imports and exports was multiplied tenfold between 1851 and 1853.

The colony of Victoria was constituted a separate province in July 1851, Mr Latrobe being appointed governor, followed by Sir Charles Hotham and Sir Henry Barkly in succession. The more rapid increase of Victoria since that time, in wealth and number of inhabitants, has gained it a pre-eminence in the esteem of emigrants; but the varied resources of New South Wales, and its greater extent of territory, may in some degree tend to redress the balance, if not to restore the character of superior importance to the older colony.

The separation of the northern part of eastern Australia, under the name of Queensland, from the original province of New South Wales, took place in 1859. At that time the district contained about 25,000 inhabitants; and in the first six years (as Sir George Bowen, the first governor, observed in 1865) its population was quadrupled and its trade trebled.

It appears, from a general view of Australian progress in the last twenty years, that the provinces less rich in gold than Victoria have been enabled to advance in prosperity by other means. Wool continues the great staple of Australia. But New South Wales, possessing both coal and iron, is becoming a seat of manufactures; while Queens-

AUSTRIA-HUNGARY



ENCYCLOPÆDIA BRITANNICA. NINTH EDITION.

land is also favoured with much mineral wealth, including tin. The semi-tropical climate of the latter colony is suitable for the culture of particular crops, needing only a supply of other than European labour. Meantime South Australia, besides its production of copper and a fair share of wool, has become the great wheat-growing province of the continent.

The separate colonies of Australia are still in a somewhat transitional state, emigration being so continuous, and the country to be yet occupied so extensive. For this and for other reasons, therefore, it may be more fitting to describe the several colonies, with respect to their industrial and social conditions, under their respective names. To enable the reader, however, to judge of the general position of the provinces at a recent date, the following statistics are appended :—

Name of Colony	Estimated Population at Close of 1873.	Revenue of 1873.	Public Debt on Dec. 31, 1873.	Value of Imports for 1873.	Value of Exports for 1873.
		£	£	£	£
Victoria	790,492	3,943,691	12,445,722	16,5[illegible],856	15,302,454

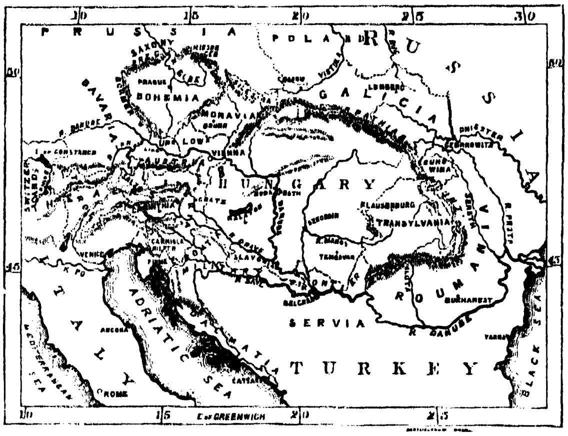
(R. A.)

AUSTRIA

Plate III.

AUSTRIA, or more strictly AUSTRIA-HUNGARY (Ger. *Oesterreich* and *Oesterreich-Ungarn*), is an extensive country in the southern portion of Central Europe, lying between long. 9° and 26° E., and lat. 42° and 51° N. It thus extends through 17 degrees of longitude and 9 degrees of latitude, and has an area of about 240,000 English square miles. With the exception of the islands in the Adriatic, and the narrow projecting tract of Dalmatia, it forms a compact region of country, but of an irregular shape. It is surrounded on all sides by other countries, except where it borders upon the Adriatic, which is about one-fifth of the entire extent of its boundaries. Of the rest, about one-third on the W. and N. is formed by the German empire (Bavaria, Saxony, and Prussia), a third on the S. and E.



Sketch Map of Austria.

by the Turkish empire and the Danubian Principalities, and the remaining third by Russia on the N.E. and Switzerland and Italy on the S.W. The boundaries are formed in some parts by river courses, in others by mountain ranges, and sometimes they extend through an open country. As compared with France, Austria has a form nearly as compact, but its frontiers are by no means so well defined or so strongly protected by natural barriers. It ranks third in extent among the countries of Europe (after Russia and Sweden), and fourth in point of population (after Russia, the German empire, and France).

Austria is, after Switzerland, the most mountainous country of Europe, and about four-fifths of its entire area is more than 600 feet above the level of the sea. The mountains are frequently covered with vegetation to a great elevation. At the base are found vines and maize; on the lower slopes are green pastures, or wheat, barley, and other kinds of corn; above are often forests of oak, ash, elm, &c.; and still higher the yew and the fir may be seen braving the fury of the tempest. Corn grows to between 3400 and 4500 feet about the level of the sea, the forests extend to 5600 or 6400 feet, and the line of perpetual snow is from 7800 to 8200 feet. In some parts, however, particularly in Tyrol, Styria, Carinthia, and Carniola, the mountains appear in wild confusion, with rugged peaks and bare precipitous sides, forcibly reminding the traveller of Switzerland. Tyrol in particular has, like that country, its cascades, its glaciers, its perpetual snows, and its avalanches.

The Alps occupy the south-west portion of the country, and form its highest lands. They are distinguished by various names, as the Rhætian, Noric, Carnic, Julian, and Dinaric Alps. The Rhætian or Tyrolese Alps enter Tyrol from the Swiss canton of the Grisons, and are the loftiest range in the country, a number of the summits rising to the height of 12,000 feet, and the highest, the Orteler Spitze, attaining a height of 12,814 feet above the level of the sea. They divide into three principal chains, the most southern of which occupies the southern portion of Tyrol, and contains the Orteler Spitze, and others of the loftiest points in the country. The middle or principal chain extends in an easterly direction to the borders of Salzburg and Carinthia, and has many of its peaks covered with perpetual snow. The northern chain is inferior in elevation to the others, and few of its most elevated points reach the snow-line. The Noric Alps are a continuation of the Rhætian eastward, passing through Salzburg, Styria, Carinthia north of the Drave, Lower and Upper Austria, to Hungary, where they gradually sink into the plains. They comprise three chains, a main chain and two lesser chains proceeding northward—the one the Salzburg, the other the Styria-Austrian Alps. The main chain, the Noric Alps in a stricter sense, traverses Salzburg, Carinthia, and Styria, and has a length of about 170 miles, some of its peaks rising to the height of 12,000 feet. The Carnic or Carinthian Alps are also an offshoot of the Rhætian Alps eastward, occupying the south-east of Tyrol, Carinthia, and the north of Carniola. They form several branches, and some of the summits are over 9000 feet high. The Julian or Carniolan Alps extend in a south-easterly direction though Carniola and Croatia. They present little of an Alpine character, and with one or two exceptions nowhere rise to the height of 5000 feet. They are for the most part bare and rugged. The Dinaric Alps are a continuation of the preceding, extending through Croatia and Dalmatia, and resemble them in character. The highest point, Mount Dinara, from which they take their name, is 5956 feet above the level of the sea.

After the Alps, the most important mountain system of Austria is the Carpathians, which occupy its eastern and north-eastern portions, and stretch in the form of an arch

through Silesia, Moravia, Galicia, Hungary, and Transylvania. They have an extent of about 650 miles, and are divided into three principal groups—the Hungarian Carpathians, the Carpathian Waldgebirge or Forest Mountains, and the Transylvanian Highlands. The Hungarian Carpathians stretch from west to east, through Hungary, Moravia, Silesia, and Galicia for about 200 miles, and comprise various smaller groups, among which are the Beskides, the Little Carpathians, and the Central Carpathians or the Tatra Mountains. This last group constitutes the highest portion of the Carpathians, having an average elevation of over 6000 feet, and its two principal summits, the Eisthaler Thurm and the Lomnitzer Spitze, having a height of 8378 and 8222 feet respectively. In character it resembles the Alps more than the Carpathians, having rugged precipitous sides, deep chasms, snows, glaciers, cascades, &c. The Waldgebirge, or Forest Mountains, are a series of moderate elevations, for the most part wooded, and stretching for about 160 miles through Hungary, Galicia, and Buckowina, with an average breadth of about 45 miles. They are in general from 3000 to 6000 feet in elevation, the highest point, Pietrozza, rising to 7086 feet. The Transylvanian Highlands extend over Transylvania, a part of Hungary, and the Military Frontier, into Moldavia and Wallachia. They have a length of about 350 miles, and breadth of from 30 to 90. Several of the summits rise to the height of 8000 feet. The sides of the Carpathian mountains are generally covered with forests to a considerable height.

The Hercynian mountain system spreads itself over Bohemia, Silesia, Moravia, and the middle and northern portions of Upper and Lower Austria. It includes the lesser systems of the Bohemian Forest, the Erzgebirge, the Riesengebirge, and the Sudetes. The Bohemian Forest is a series of wooded heights on the confines of Bohemia and Bavaria, and extending south from the Eger to the Danube. Its highest point is 4610 feet above the sea. The Erzgebirge, or Ore Mountains, commence on the left bank of the Elbe, run eastward between Bohemia and Saxony, and terminate near the sources of the White Elster. None of the summits rise to the height of 4000 feet. The Riesengebirge or Giant Mountains are on the confines of Bohemia towards Prussian Silesia, and have their highest point, Schneekoppe or Riesenkoppe, 5330 feet above the sea. The Sudetes is a name sometimes given to all the mountains of Northern Bohemia, but it more properly belongs to that range which runs between Moravia and Prussian Silesia, from the March to the Oder. The highest summit, the Spieglitzer Schneeberg, is 4774 feet high.

Geology. The great central chain of the Alps consists of primitive rocks, principally gneiss, mica slate, and granite. Occasionally clay-slate, greywacke, and limestone overlie these rocks. Iron ore is very abundant here, and gold and copper are found. The northern and southern ranges of the Alps are composed of limestone. In the southern range the limestone rests upon gneiss, which crops out in some parts. Iron, copper, lead, and zinc ores, and quicksilver are found in some parts to a large extent. In the northern range the limestone is in some places covered with clay-slate, greywacke, and transition limestone. In the north the limestone is covered with sandstone, which extends in an almost continuous line from the Lake of Constance to the neighbourhood of Vienna. In this district a number of beds of coal are found. The central range of the Carpathians is formed chiefly of gneiss, granite, clay-slate, greywacke, and transition limestone, frequently covered with extensive patches of Tertiary formations. North and south of this are ranges of sandstone mountains, on which diluvial and alluvial deposits are also found. The northern sandstone range is rich in salt; the central chain abounds in iron and copper ore; and the gneiss and granitic mountains of Hungary and Transylvania are rich in ores of gold and silver. Numerous beds of coal are also found in the later formations. The Bohemian and Moravian mountain system is composed chiefly of gneiss and granite. Basalt, clinkstone, greenstone, and red sandstone are also common. Silver and lead mines are extensively worked, also mines of zinc and iron. Coal is abundant here. The plain and hilly parts of the country belong chiefly to the middle or Miocene period of the Tertiary formation, and comprise sand, gravel, clay-marl, &c.

Rivers. As the highlands of Austria form part of the great watershed of Europe which divides the waters flowing northward into the North Sea or the Baltic, from those flowing southward or eastward into the Mediterranean or the Black Sea, its rivers flow in three different directions—northward, southward, and eastward. With the exception of the small streams belonging to it which fall into the Adriatic, all its rivers have their mouths in other countries, and its principal river, the Danube, has also its source in another country. This, which after the Volga is the largest river of Europe, rises in the grand duchy of Baden, flows through Würtemberg and Bavaria, and is already navigable when it enters Austria, on the borders of which it receives the Inn, a river which has as large a body of water as itself. It has a course of about 820 miles within the country, which is about 48 per cent. of its entire length. Where it enters it is 898 feet above the level of the sea, and where it leaves only 132 feet. It has thus a fall within the country of 766 feet, and is at first a very rapid stream, but latterly a very slow one. Its affluents, after the Inn, are at first generally small, the principal being the Traun, the Enns, and the March. In Hungary it receives from the Carpathians the Waag, Neutra, Gran, and Eipel; and from the Alps the Drave, the Mur, and the Save. But the principal affluent of the Danube is the Theiss, which rises in the Carpathians, and drains nearly the whole of the eastern half of Hungary. The country drained by the Danube is formed into several basins by the mountains approaching its banks on either side. The principal of these are the Linz and Krems basins, the Vienna basin, and the little and great Hungarian basins. Between this last and the plains of Wallachia, it passes through the narrow rocky channels of Islach, Kasan, and the Iron Door, where the fall is about 41 feet in less than half a mile. The Dniester, which, like the Danube, flows into the Black Sea, has its source in the Carpathians in Eastern Galicia, and pursues a very winding course towards the south-east. It receives its principal affluents from the Carpathians, and drains in Austria a territory of upwards of 12,000 English square miles. It is navigable for about 300 miles. The Vistula and the Oder both fall into the Baltic. The former rises in Moravia, flows first north through Austrian Silesia, then takes an easterly direction along the borders of Prussian Silesia, and afterwards a north-easterly, separating Galicia from Russian Poland, and leaving Austria not far from Sandomir. Its course in Austria is 240 miles, draining an area of 15,500 square miles. It is navigable for nearly 200 miles, and its principal affluents are the Save and the Bug. The Oder has also its source in Moravia, flows first east, and then north-east through Austrian Silesia into Prussia. Its length within the Austrian territory is only about 55 miles, no part of which is navigable. The only river of this country which flows into the North Sea is the Elbe. It has its source in the Riesengebirge, not far from the Schneekoppe, flows first south, then east, and afterwards north-east through Bohemia, and then enters Saxony. Its principal affluents are the Adler, Iser, and Eger, and, most important of all, the Moldau. The last, from the length of its course,

and the quantity of water which it brings down, is entitled to be considered the main stream. It has a course of 260 miles, and is navigable for 190. The Elbe itself has a course within the Austrian dominions of 185 miles, for about 65 of which it is navigable. It drains an area of upwards of 21,000 square miles. The Rhine, though scarcely to be reckoned a river of the country, flows for about 25 miles of its course between it and Switzerland. The principal river of Austria which falls into the Adriatic is the Adige. It rises in the mountains of Tyrol, flows south, then east, and afterwards south, into the plains of Lombardy. Its principal affluent is the Eisack. Of the streams which have their course entirely within the country, and which fall into the Adriatic, the principal is the Isonzo, 75 miles in length, but navigable only for a short distance from its mouth.

Lakes. The lakes and marshes of Austria are very numerous, and some of them are of great extent. The lakes lie principally in the valleys among the Alps, and the marshes are frequent along the courses of the rivers. The largest lake of Austria is the Balaton, in Hungary, which is about 46 miles in length by 18 in breadth, and, including the swamps in connection with it, covers an area of 500 square miles. The Neusiedler, also in Hungary, is 18 miles in length, by from 4 to 7 in breadth, and covers an area of 106 square miles. Among the many smaller ones the principal are the Traunsee, Attersee, Wörthersee, Mondsee, &c. No other European country equals Austria in the number and value of its mineral springs. No fewer than 1500 of these are reckoned, and they occur principally in Bohemia and Hungary. In the former are Karlsbad, Marienbad, Franzensbad, Teplitz, Püllna, and Seidlitz.

Climate. The climate of Austria, in consequence of its great extent, and the great differences in the elevation of its surface, is very various. It is usual to divide it into three distinct zones. The most southern extends to 46° N. lat., and includes Dalmatia and the country along the coast, together with the southern portions of Tyrol and Carinthia, Croatia, Slavonia, and the most southern part of Hungary. Here the seasons are mild and equable, the winters are short (snow seldom falling), and the summers last for five months. The vine and maize are everywhere cultivated, as well as olives and other southern products. In the south of Dalmatia tropical plants flourish in the open air. The central zone lies between 46° and 49° N. lat., and includes Lower and Upper Austria, Salzburg, Styria, Carinthia, Carniola, Central and Northern Tyrol, Southern Moravia, a part of Bohemia, the main portion of Hungary, and Transylvania. The seasons are more marked here than in the preceding. The winters are longer and more severe, and the summers are hotter. The vine and maize are cultivated in favourable situations, and wheat and other kinds of grain are generally grown. The northern zone embraces the territory lying north of 49° N. lat., comprising Bohemia, Northern Moravia, Silesia, and Galicia. The winters are here long and cold; the vine and maize are no longer cultivated, the principal crops being wheat, barley, oats, rye, hemp, and flax. The mean annual temperature ranges from about 59° in the south to 48° in the north. In some parts of the country, however, it is as low as 46° 40′ and even 36°. In Vienna the average annual temperature is 50°, the highest temperature being 94°, the lowest 2° Fahr. In general the eastern part of the country receives less rain than the western. In the south the rains prevail chiefly in spring and autumn, and in the north and central parts during summer. Storms are frequent in the region of the South Alps and along the coast. In some parts in the vicinity of the Alps the rainfall is excessive, sometimes exceeding 60 inches. It is less among the Carpathians, where it usually varies from 30 to 40 inches. In other parts the rainfall usually averages from 20 to 24 inches, but in the plains of Hungary it is as low as 16.

Flora. From the varied character of its climate and soil the vegetable productions of Austria are very various. It has floras of the plains, the hills, and the mountains; an alpine flora, and an arctic flora; a flora of marshes, and a flora of steppes; floras peculiar to the clay, the chalk, the sandstone, and the slate formations. The number of different species is estimated at 12,000, of which one-third are phanerogamous, or flowering plants, and two-thirds cryptogamous, or flowerless. The crown-land of Lower Austria far surpasses in this respect the other divisions of the country, having about four-ninths of the whole, and not less than 1700 species of flowering plants. Hungary, Bohemia, Moravia, and Galicia are the principal corn-growing regions of the country; and Tyrol, Salzburg, and Upper Styria are the principal pastoral regions.

Animals. The animal kingdom embraces, besides the usual domestic animals (as horses, cattle, sheep, swine, goats, asses, &c.), wild boars, deer, wild goats, hares, &c.; also bears, wolves, lynxes, foxes, wild cats, jackals, otters, beavers, polecats, martens, weasels, and the like. Eagles and hawks are common, and many kinds of singing birds. The rivers and lakes abound in different kinds of fish, which are also plentiful on the sea-coast. Among insects the bee and the silkworm are the most useful. The leech forms an article of trade. In all there are 90 different species of mammals, 248 species of birds, 377 of fishes, and more than 13,000 of insects.

Divisions. Austria comprises five countries, each bearing the name of kingdom—viz., Hungary, Bohemia, Galicia, Illyria, and Dalmatia; one archduchy, Austria; one principality, Transylvania; one duchy, Styria; one margraviate, Moravia; and one county, Tyrol. These are now divided into provinces, which are called *crown-lands*, and of which at present there are 18, 14 being in Austria Proper, and 4 in Hungary. The following table gives the area and civil population of the different crown-lands in 1857 and at 31st December 1869. The first 14 crown-lands constitute Austria Proper, and the remaining 4 form the kingdom of Hungary. Görtz, Istria, and Trieste are also known as the Maritime District.

Crown-lands.	Areas in English Miles.	Population in 1857.	Population in 1869.		
			Males.	Females.	Total.
Lower Austria	7,630	1,681,697	967,087	987,164	1,954,251
Upper Austria	4,617	707,400	358,117	373,462	731,579
Salzburg	2,757	146,760	73,468	77,942	151,410
Styria	8,642	1,056,773	555,289	576,020	1,131,309
Carinthia	3,992	332,456	161,519	174,881	336,400
Carniola	3,844	451,941	220,009	243,264	463,273
Görtz, Istria, & Trieste	3,074	520,978	288,293	293,786	582,079
Tyrol and Vorarlberg	11,287	851,016	429,241	449,666	878,907
Bohemia	19,997	4,705,525	2,433,629	2,672,440	5,106,069
Moravia	8,555	1,867,094	948,206	1,049,691	1,997,897
Silesia	1,981	443,912	242,574	269,007	511,581
Galicia	30,212	4,597,470	2,660,518	2,757,498	5,418,016
Buckowina	4,022	456,920	255,919	256,045	511,964
Dalmatia	4,923	404,499	220,169	222,617	442,796
Hungary	82,605	9,900,785	5,499,462	5,618,161	11,117,623
Transylvania	21,159	1,926,797	1,051,145	1,050,582	2,101,727
Croatia and Slavonia	7,421	876,009	495,962	501,644	997,606
Military Frontier	12,919	1,064,922	606,991	593,380	1,200,371
Total	239,637	31,992,954	17,467,598	18,167,260	35,634,858

A more recent report states that the population of Austria Proper had risen from 20,210,000 in 1869 to 20,970,000 in 1873—the male population having increased from 9,810,000 to 10,200,000, and the females from 10,400,000 to 10,770,000. The most thickly populated crown-land is Silesia; the most thinly, Salzburg.

Population. The civil population of Austria in 1818 amounted to 29,769,263, in 1830 it had increased to 34,082,469, in 1842 to 35,295,957, in 1857 to 37,339,012, and in 1869 to 35,634,858. Between the two last dates it had lost its Lombardo-Venetian territories, with more than 5,000,000

inhabitants. In Austria Proper the number of births in 1869 was 812,474, of which 419,374 were males and 393,100 females; 699,047 were legitimate, and 113,427 illegitimate, and 17,114 were still-born. The number of deaths among children up to 5 years of age was 281,643—152,294 being males, and 129,349 females. The number of marriages that took place during that year was 208,787, of which 164,018 were between parties neither of whom had been previously married; 8670 between parties both of whom had been previously married; 23,533 between widowers and unmarried females, and 12,566 between widows and unmarried males. The total number of deaths during 1869 was 583,995, of which 302,104 were males and 281,891 females. Of these the ages of 28 males and 40 females are given as over 100 years. Violent deaths carried off 5988 males and 1939 females, of whom 1110 males and 265 females had committed suicide, 244 males and 82 females were murdered, and 4 males executed. In Austria Proper there were 738 cities and large towns, 1270 market towns, 52,919 villages, and 2,766,314 inhabited and 121,045 uninhabited houses. In Hungary there were 189 cities and large towns, 769 market-towns, 16,373 villages, and 2,450,213 houses. The cities containing more than 100,000 inhabitants in 1869 were Vienna (833,855), Pesth (201,911), and Prague (157,275). Seven cities contained between 50,000 and 100,000 inhabitants; 42 between 20,000 and 50,000; and 90 between 10,000 and 20,000.

Races. The population of Austria is made up of a number of distinct races, differing from each other in manners, customs, language, and religion, and united together only by living under the same government. The most numerous race is the German, amounting to 9,000,000, and forming 25 per cent. of the entire population. They are found more or less in all the crown-lands, but are most numerous in Lower and Upper Austria, Salzburg, Styria, Carinthia, and Northern Tyrol. The different Slavonic races number together 16,540,000, or 46 per cent. The principal Slavonic races are,—in the north, the Czechs and Moravians (4,480,000), who, together with the Slovacks in the Western Carpathians (1,940,000), form 18 per cent. of the entire population, and the Poles (2,370,000) and the Ruthens (3,360,000) occupying Galicia; and in the south, the Slovens (1,220,000), the Croats (1,520,000), and the Serbians (1,651,000). The northern Slavonians are found chiefly in Bohemia, Moravia, Galicia, and the north of Hungary; the southern in Carniola, Dalmatia, Croatia, Slavonia, and the Military Frontier. The Magyars or Hungarians occupy chiefly Hungary and Transylvania, and number 5,590,000, or 16 per cent. of the whole population. The Rumäni or Wallachians number 2,940,000, or over 8 per cent.; the Jews, 1,105,000, or 3 per cent.; the Italians, 515,000, or 1·4 per cent.; and the gipsies, 140,000. The rest consist of Armenians, Bulgarians, Albanians, Greeks, &c.

Religion. Austria has always remained strongly attached to the Roman Catholic Church. Her sovereigns, however, have in general resisted the temporal pretensions of the popes, and reserved to themselves certain important rights, such as the imposing of taxes on church property, the nomination of bishops and archbishops, and the option of restricting, or even prohibiting, the circulation of Papal bulls. About two-thirds of the people, or nearly 24,000,000, profess the Roman Catholic religion. If, however, we deduct the kingdom of Hungary and Galicia, where less than one-half of the people are Roman Catholics, the proportion in the rest of the country is much increased. In some parts the proportion to the entire population is as high as 90 to 98 per cent. The Greek Catholics number in Austria Proper 2,342,168 (almost all in Galicia), and in Hungary 1,599,628. The Eastern Greek Church numbers 461,511 adherents in Austria, and 2,589,319 in Hungary. Of the Protestant denominations, the Lutherans are more numerous in the western half of the empire, the Calvinists in the eastern. The numbers are—in Austria Proper, Lutherans, 252,327, and Calvinists, 111,935; in Hungary, Lutherans, 1,365,835, Calvinists, 2,143,178. The principal other religions are the Jewish, 1,375,861 (nearly half of them in Galicia); Armenian, 10,133; Unitarian, 55,079 (nearly all in Transylvania). The Catholic Church (including the Greek and Armenian Catholics) has 11 archbishops, 24 suffragan bishops, 2 vicariate bishops, and 1 military bishop, in Austria Proper, and 5 archbishops and 23 bishops in Hungary. Altogether there are about 34,000 ecclesiastics, and 950 convents, with 8500 monks and 5700 nuns. The Oriental Greek Church has, in Austria Proper, 3 bishops (1 in Buckowina and 2 in Dalmatia), and in Hungary, the patriarch of Karlowitz, the archbishop of Herrmannstadt, and 8 bishops, with, in all, 4000 priests, and 40 convents, with 300 monks.

Education. Previous to 1848 Austria was very far behind in the matter of education; but since that time great improvements have been effected, and an entire change has taken place. This subject now receives the greatest attention; schools of all kinds have been established throughout the country, improved systems of teaching have been introduced, and instruction is open to all without regard to class or creed at a very small cost, or even gratuitously. It still continues, however, to be in great measure under the control of the priests, and many of the teachers are ecclesiastics. The Roman Catholic religion forms an essential part of the instruction in all schools, except those for special subjects. The Oriental Greek and Protestant Churches have, as a rule, their own common schools, and where this is not the case, they have to send their children to the Catholic schools. The Jews also, in places where they have no special schools, are obliged to send their children to Christian schools.

The various educational institutions may be arranged under four classes—(1.) The lower or common schools; (2.) The higher or middle schools; (3.) The universities, academies, and technical schools; (4.) The special schools (for particular branches of science or art). All children from 6 to 12 years of age are bound to attend the common schools. This law, however, would appear to be not very strictly carried out, for of the number of 2,219,917 children who ought to have been attending the common schools in Austria Proper in 1868, the number given as actually at school is only 1,691,349, or about 76 per cent. This percentage, moreover, varies greatly in different parts of the country, being in some, as Tyrol, Salzburg, Moravia, and Upper and Lower Austria, as high as 98 or 100, and in Styria and Carinthia from 93 to 96; in others, as in Carniola, only 56, in the Maritime District 47, Dalmatia 28, Galicia 27, Buckowina 20. The proportion for the whole of Hungary is 88 per cent., and it is higher in the western than in the eastern half of the kingdom. The number of common schools in Austria in 1868 was 15,054, with 32,137 male and 2814 female teachers, 12,225 of the former being ecclesiastics, and 1036 of the latter nuns; in Hungary the number of schools was over 16,000, and of teachers 28,000. In connection with many of these schools there are training institutions for teachers, industrial schools for girls, and trade and agricultural schools for boys. The middle schools are the gymnasia, real-gymnasia, and real-schools. A complete gymnasium provides for a course of eight years' study, divided into two parts of four years each. The lower course not only prepares for the higher, but is also complete in itself for those who do not wish to advance farther. The branches of study include Latin, Greek, and modern languages, geography, history, religion, mathematics, natural history, physics, writing, drawing, singing, and gymnastics. In passing from one class to another the scholars undergo a very searching examination. The real-schools, or middle industrial schools, have been established since 1848, and are designed to impart technical knowledge, and afford a suitable training to those intending to follow industrial pursuits. They are divided into two courses of three years each, a lower and an upper—the former serving not only as a preparation for the latter, but forming also an independent course, fitting for the lower kinds of industrial occupations. The branches taught include geography, history, arithmetic, mathematics, writing, book-keeping, exchange, natural history, technology, drawing, &c. The real-gymnasia are a class of institutions intermediate between these two, partaking of the

character of both. In Austria Proper there were, in 1871, 92 gymnasia, with 1647 teachers (518 being ecclesiastics) and 26,102 scholars; 31 real-gymnasia, with 375 teachers (66 ecclesiastics) and 45,290 scholars; and 33 real-schools, with 777 teachers (91 ecclesiastics) and 15,622 scholars. In Hungary there were 142 gymnasia, 1 real-gymnasium, and 25 real-schools, having in all 33,000 scholars. There are six universities in Austria Proper (Vienna, Grätz, Innsbrück, Prague, Cracow, Lemberg), and one in Hungary (Pesth), with, in all, 707 professors and 10,900 students. Each university (except Lemberg, which has no medical faculty) has faculties for Roman Catholic theology, law and political economy, medicine and surgery, and philosophy. The theological and law courses occupy four years each, the medical five, and the philosophical three. Of the students, 40 per cent. were at the university of Vienna, 18 at Pesth, 16 at Prague, 10 at Lemberg, and 6½ at Grätz. Of the 8532 students attending the six Austrian universities, 1888 were receiving free instruction and 924 were stipendists, and in addition to this, 682 were paying only half fees. The technical high schools or academies have for their object the imparting of a high scientific education. The students generally enter them from the upper real-schools, and the complete technical course extends over five years. There are eight of these institutions in Austria Proper, having in all 284 professors and teachers, and 3179 scholars, of whom 1501 were receiving free instruction, and 231 were stipendists. The principal of these is the Polytechnic institution in Vienna, which has 79 professors and teachers, and 782 scholars. Among the special educational institutions may be mentioned about seventy theological seminaries connected with the Catholic Church, and a number of similar institutions connected with the Eastern Greek and Protestant Churches; a rabbinical school (in Presburg); academies for law, mining, navigation, commerce, agriculture, and the management of forests; normal and military schools; schools for surgery and midwifery; veterinary schools, &c. There are also a number of private schools of various kinds, schools for the deaf and dumb and blind, orphan institutions, &c. In connection with the universities and many of the higher educational institutions are to be found libraries, museums of natural history and antiquities, botanic gardens, observatories, chemical laboratories, &c. There also exist numerous learned and scientific societies. The intellectual progress of Austria is, of late years, particularly manifest in the departments of law, medicine, natural science, history, and Oriental languages.

dustries. The majority of the people of Austria are engaged in agricultural pursuits or in connection with the forests, the proportion varying in different parts from 50 to 80 per cent. of the entire population. The proportion of those engaged in trade or manufacture varies, amounting to 30 per cent. in Lower Austria, 24 in Bohemia, 22 in Moravia and Silesia, 19 in Upper Austria, 14 in Tyrol, 13 in Salzburg, 11 in Carinthia, 9 in Carniola, 5 in Buckowina, and 4 in Galicia and Dalmatia. In Dalmatia about 8 per cent. of the people are employed in navigation and the fisheries.

The productive land of Austria Proper is estimated at 89·6 per cent. of its superficial area, and that of Hungary at 84·4—making 86·9 per cent. of the whole country. Farther, the arable land in Austria forms 31·6 per cent., the vineyards 0·7, gardens and meadows 11·7, pasturage 14·7, and forests 30·9. In like manner, in Hungary the arable land forms 30·6 per cent., vineyards 1·2, gardens and meadows 12·8, pasturage 13·2, and forests 26·6. The principal product of the arable land is grain, of which the annual yield is over 400,000,000 bushels. Of this about one-fifth is wheat, one-fourth rye, one-fourth oats, one-seventh maize, one-seventh barley, and the rest buck-wheat and millet. The principal grain-producing districts are Hungary, Bohemia, Galicia, Moravia, and Lower and Upper Austria. In agriculture Austria is still behind many other countries, but great improvements have of late years taken place. Flax, hemp, and beet are chiefly found in Silesia, Moravia, Bohemia, and Hungary; hops in Bohemia, and tobacco (which is a state monopoly) only in Hungary, Galicia, and Tyrol. Among the other products may be mentioned pease, beans, potatoes, turnips, rape seed, cabbages, &c. Though the vineyards are not very extensive, a considerable quantity of wine is produced, and some of the Hungarian wines, as Tokay, are justly celebrated. The annual yield of wine is about 375,000,000 gallons, of which 72 per cent. is from Hungary and the neighbouring districts, 6½ from Lower Austria, 5 from Southern Tyrol, 4½ from Styria, 4 from Dalmatia, 3½ from Moravia, and 2 from the Maritime District. The principal garden products are fruit and kitchen vegetables. The best fruit districts are Moravia, Transylvania, Hungary, Bohemia, Upper Austria, and Styria. Certain districts are distinguished for particular kinds of fruit, as Tyrol for apples, Hungary for melons, Dalmatia for figs, pomegranates, olives, &c. In the south of Dalmatia the palm grows in the open air, but bears no fruit. The chestnut, olive, and mulberry trees are common in the south—the olive chiefly in Dalmatia, the Maritime District, and Southern Tyrol; the mulberry tree in Southern Tyrol, the south of Hungary, Slavonia, and Styria. The forests occupy nearly one-third of the productive area of the country, and cover 66,600 English square miles. They are much more extensive in the eastern than in the western half of the country, the relative proportions being 62 per cent. in the former, and 38 in the latter. They are found particularly in the region of the Carpathians, and especially in Galicia and Buckowina. The Alpine regions are generally well wooded, as is also the country of the Sudetes. The forests are chiefly of oak, pine, beech, ash, elm, and the like, and are estimated to yield annually over 27,000,000 cords of building wood and firewood.

Horses. Austria is distinguished for the number and superiority of its horses, for the improvement of which numerous studs exist over the country. The breeding of horses is more or less extensively carried on in all the crown-lands, but more especially in Hungary, Transylvania, Buckowina, Galicia, Styria, Bohemia, Moravia, and Upper and Lower Austria. The total number of horses in the country in 1870 was 3,525,842, of which 2,158,819 were in Hungary. All kinds of horses are represented, from the heaviest to the lightest, from the largest to the smallest. The most beautiful horses are found in Transylvania and Buckowina, the largest and strongest in Salzburg. The horses of Styria, Carinthia, Northern Tyrol, and Upper Austria are also famous. In Dalmatia, the Maritime District, and Southern Tyrol, horses are less numerous, and mules and asses in a great measure take their place. Of the 13,891 mules in the country, 45 per cent. were in Dalmatia, and 30 per cent. in the Maritime District and Southern Tyrol; and of the 61,831 asses, 28 per cent. were in the former and 21 in the latter. The Hungarian crown-lands contain 2266 mules and 30,482 asses.

Cattle. Austria cannot be said to be remarkable as a cattle-rearing country. Indeed, except in certain districts, particularly among the Alps, it must be considered to be much behind in this branch of industry. The finest cattle are to be found in the Alpine regions; in other parts the breeds are generally very inferior. The Hungarian crown-lands, however, have of late years been improving in this respect. The country numbered 12,704,405 head of cattle in 1870, of which 5,279,193 were in Hungary, 2,070,572 in Galicia, and 1,602,015 in Bohemia. The cattle of the eastern half of the country considerably outnumbered those of the western; but in quality the latter were far superior to the former. In Hungary and Transylvania there are about 72,000 buffaloes. The rearing of sheep receives a large share of attention, and is carried on to a considerable extent in all the crown-lands, and in some very extensively. Much has been done of late years in the way of improving the breeds, more particularly in Moravia, Silesia, Bohemia, Upper and Lower Austria, and Hungary. The main object has been the improvement of the wool, and with this view the merino and other fine-wooled breeds have been introduced. Some attention, however, is also given to the fattening properties. For mutton, the best sheep are those of Lower Carinthia, the Maritime District, Dalmatia, and the Military Frontier. The sheep are frequently driven from one part of the country to another for the sake of pasture, and even into other countries, as Lombardy, Turkey, and the Danubian Principalities. The number of sheep in the country in 1870 was 20,000,000, of which 15,000,000 were in the kingdom of Hungary. The goat, which has been called the poor man's cow, is also to be found in all parts of the country, but more particularly in the mountainous districts and among the poorer peasantry. The total number in the country in 1870 was 1,552,000, of which 573,000 were in Hungary. Dalmatia, however, is the great country of the goats, where they number 280,656, after which follow Bohemia with 194,273, and Tyrol with 137,698. The number of swine was 6,984,752, of which 4,443,279 were in Hungary. They are naturally most numerous in those crown-lands which contain extensive oak and beech forests, or which have many distilleries. Hence they are mostly found in Hungary, Transylvania, the Military Frontier, Galicia, Styria, and Bohemia.

Bees are extensively kept, particularly in the crown-lands of Lower Austria, Hungary, Galicia, and Transylvania. There were in 1870 15,300,000 bee-hives in the country, yielding 7,750,000 lb of honey and 340,000 lb of wax. The silk-worm is cultivated in certain parts of the southern districts, particularly in Southern Tyrol, which yields 2,200,000 lb of cocoons, being nearly double that of all the rest of the country put together. The rivers and lakes in general abound with fish, which are also plentiful along the coast. In Dalmatia, in particular, fishing constitutes an important branch of industry, affording employment to many of the population. Leeches are common in the swamps, and form a considerable article of export. The average annual value of the produce of the land and forests, including the cattle, and hunting and fishing, is estimated at £212,000,000. The value of the real property, including the cattle and agricultural implements, is given at £782,000,000.

Minerals. In the extent and variety of its mineral resources Austria ranks among the first countries of Europe. Besides the noble metals, gold and silver, it abounds in ores of more or less richness of iron, copper, lead, and tin; while in less abundance are found zinc, antimony, arsenic, cobalt, nickel, manganese, bismuth, chromium, uranium, tellurium, sulphur, graphite, asphalt, rock-salt, coal, and petroleum. There are also marble, roofing-slate, gypsum, porce-

lain earth, potter's clay, and precious stones. The crown-lands in which mining operations are chiefly carried on are Styria (iron and coal), Carinthia (lead and iron), Carniola (quicksilver), Hungary (gold, silver, copper, iron, and coal), Transylvania (gold and silver), Salzburg (iron), Bohemia (silver, lead, iron, and coal), Moravia (iron and coal), Galicia (salt). The chief places where *gold* and *silver* ores are found are—(1.) At Zalathna in Transylvania, on the southern range of the Behar Mountains, where affluents of the Körös and Maros take their rise, in which, as well as in the Theiss and the Danube, gold is also found; (2.) The district of Schemnitz and Kremnitz in Hungary; (3.) Pribram and Joachimsthal in Bohemia. Nearly 3,000,000 cwt. of gold and silver ores is obtained annually, from which 64,298 oz. of gold and 1,476,000 oz. of silver are extracted. Of the gold, 54 per cent. is obtained in Transylvania, and 44 in Hungary; and of the silver ore, 65 per cent. is raised in Hungary, 27 in Bohemia, and 5½ in Transylvania. Iron is found more or less in all the crown-lands except Upper Austria, the Maritime District, and Dalmatia; but it is most plentiful and best in quality in Styria and Carinthia. The amount of raw and cast iron annually obtained from the ore raised in the country is 7,600,000 cwt., of which 28 per cent. is from Styria, 15 from Carinthia, 12½ from Bohemia, 11½ from Moravia, 16 from Upper Hungary, 6½ from other parts of the kingdom of Hungary, and the remainder from the other crown-lands. The principal place where *copper* is obtained is the neighbourhood of Schmölnitz in Hungary. The quantity for the whole country amounts to 1,500,000 cwt. of ore, from which 65,000 cwt. of pure metal is obtained. Of this, 80 per cent. is from Upper Hungary, 6 from Tyrol, and 4 from Buckowina. Carinthia is particularly rich in *lead*, and from it more than one-half (52 per cent.) of the entire quantity raised in the country is obtained. Bohemia yields 26 per cent., and Hungary 15. Altogether, 195,000 cwt. of ore, and 114,000 cwt. of pure metal is obtained. Idria in Carniola has, after Almaden in Spain, the richest *quicksilver* mine in Europe, producing 3900 cwt. of pure metal. Of the rest, Hungary produces 1120 cwt., and Transylvania 450. *Tin* is found only in Bohemia, which supplies 55,000 cwt. of ore, from which 450 cwt. of tin is obtained. *Zinc* is found chiefly in the neighbourhood of Cracow, where 146,475 cwt. of ore is raised. Austria is particularly rich in *salt*. In Galicia there exists a stratum of rock-salt many miles in extent, which is worked at Wieliczka and other places. Similar layers occur in Hungary (Marmaros) and Transylvania (at Thorda). There also exist salt springs in Galicia, in Marmaros, and in Transylvania, from which salt is largely extracted, as it is also to a considerable extent from sea water on the coast. About 3,900,000 cwt. of rock-salt is annually obtained from the mines (of which 22 per cent. is from Galicia, 24 from Marmaros, 34 from Transylvania), from the various salt springs about 2,800,000 cwt., and from the salt-works on the coast 1,400,000 cwt. Austria is possessed of almost inexhaustible stores of *coal*, and the amount annually raised exceeds 6,000,000 tons, of which 48 per cent. is in Bohemia, 12 in Hungary, 11 in Silesia, 10 in Styria, 6½ in Moravia, 2½ in Galicia, and 1½ in Carniola. Peat and clay are abundant in certain parts of the country; porcelain earth is found in Bohemia and Moravia; white, red, black, and variously-coloured marbles exist in the Alps, particularly in Tyrol and Salzburg; quartz, felspar, heavy spar, rock-crystal, asbestos, &c., are found in various parts; and among precious stones may be specially mentioned the Hungarian opals and the Bohemian garnets. The number of persons employed in the various mines in Austria Proper in 1870 was 75,451, and in the smelting and casting works, 13,857. In addition to these, 9818 persons were employed in the salt-mines and other salt-works. In Hungary 50,143 persons were employed in mining and smelting. The total annual value of the raw materials obtained from the mines is estimated at over £9,000,000, of which nearly one-half is of coal, a fifth of iron, an eighth of gold and silver, and a tenth of rock-salt.

Manufactures. The manufactures of Austria have made great progress during the last twenty years, and now some of them are extensively carried on. They include cotton, flax, hemp, woollen and silk stuffs; gold, silver, iron, lead, copper, tin, and zinc articles; leather, paper, beer, brandy, and sugar; porcelain and earthenware; chemical stuffs; scientific and musical instruments, &c. The manufactures are principally carried on in the western crown-lands, and more particularly in Bohemia, Moravia, Silesia, and Lower Austria. In Galicia and the Hungarian crown-lands the manufactures are comparatively neglected. The principal seats of the cotton, woollen, and linen manufactures are in Moravia, Silesia, Bohemia, and Vienna; of iron and steel wares in Styria and Carinthia; iron in Upper Austria; cast-iron goods in Moravia, Styria, Carinthia, and Bohemia; silk in Vienna; glass and porcelain in Bohemia; beetroot sugar in Bohemia and Moravia; leather in Bohemia, Moravia, Galicia, and Hungary; beer in Bohemia and Lower Austria; brandy in Galicia, Moravia, and Bohemia; cabinet wares and musical instruments in Vienna and Prague; and scientific and surgical instruments in Vienna.

The *cotton* manufacture has made very rapid progress, and is now one of the most extensive and flourishing in the country. In 1831 the import of cotton was 101,000 cwt., and the export 175; in 1850 the former had risen to 522,000, and the latter to 1270; and in 1870 the former was 1,100,000, and the latter 36,000 cwt. There are 172 spinning factories, with 1,750,000 spindles, in the country, almost all situated in Lower Austria, Bohemia, and Vorarlberg. There are 46 factories, with 550,000 spindles, in Lower Austria, between the Vienna Forest and the Leitha, and beside them are 7 dyeing and printing works. A principal seat of the cotton manufacture is in Northern Bohemia, from the Eger to Reichenberg, where there are no fewer than 80 spinning factories and 25 printing works. Besides these, there are 7 factories at Prague and 1 in Southern Bohemia. In Vorarlberg there are 21 factories, with 200,000 spindles; and in Upper Austria 7 factories and 6 printing works.

The *flax* and *hemp* manufacture is one of the oldest in the country, and was long the most important. In consequence, however, of the rapid advancement of the cotton manufacture it is no longer of the same importance as formerly; yet it still affords employment to a great number of persons, and is very generally extended over the country. It is principally carried on as a domestic branch of industry, and in country districts is frequently engaged in as a secondary pursuit by those employed in agricultural labours. The flax is mostly spun by hand, and the weaving confined to the commoner kinds of linen, being chiefly intended for home use. In Bohemia, Moravia, Silesia, and Upper Austria, however, this manufacture is more extensively carried on than in other parts. There are here a number of factories for the spinning of flax, and the finer kinds of linen are manufactured.

The *woollen* manufacture is also an old established branch of industry, and is actively carried on. It is estimated that about 600,000 cwt. of wool is annually spun; and there are about 230 spinning factories, with upwards of 700,000 spindles. The great seats of the woollen manufacture are in Bohemia, Moravia, Silesia, and Upper Austria. In Bohemia its great seat is in and around Reichenberg, where the annual value of the goods produced is about £1,800,000. In Moravia the principal seats are Brünn (for coarse, and also the finest sorts of cloth), Namiescht, and Iglau. In these two crown-lands is made half of the entire quantity of woollen goods produced in the country. The principal of the other seats are the districts Bielitz in Silesia, Vienna in Lower Austria, and Viktring in Carinthia (for fine goods). Vienna is also distinguished for its manufacture of shawls. The coarser kinds of woollen goods are generally manufactured over the country, and principally in the people's houses, and for home use.

The manufacture of *silk* stuffs is principally carried on in Vienna, and to a small extent in the north of Bohemia and in the Maritime District. The spinning of silk has its principal seat in Southern Tyrol, where about 550,000 lb are spun annually, besides which about 1,700,000 lb are annually brought from other countries.

The *iron* and *steel* manufactures form one of the most important branches of industry, and afford employment to a great number of persons. They are more or less extensively carried on in all the crown-lands, except the Maritime District, Dalmatia, Croatia, and Slavonia; but their principal seats are in Lower and Upper Austria, Bohemia, Moravia, Styria, and Carinthia. One of the most important of these seats is Steier and its neighbourhood, in Upper Austria, where there are about 700 establishments, producing goods—chiefly cutlery, scythes, sickles, firearms, &c.—to the value of £400,000 annually. In Styria there are large ironworks at Maria-Zell and Neuberg; and in Carinthia, at Prevali, Buchscheiden, and Ferlach. There are also large ironworks in Lower Austria, Carniola, Tyrol, Bohemia, and Moravia. The making of steam engines and other kinds of machinery is largely carried on in and about Vienna, where there are 26 establishments for this purpose. There are similar establishments in other parts of Lower Austria, in Styria, Bohemia, Silesia, and Buckowina. The Lloyds' Company has also large workshops at Trieste. About 1,100,000 cwt. of iron are annually used in the making of machinery, and about 6,600,000 cwts. in the other iron and steel manufactures, among which may be mentioned cutlery, firearms, files, wire, nails, tinplate, steel pens, needles, &c.

The principal *copper*-works are at Brixlegg and other places in Tyrol, and in Galicia, Buckowina, and Hungary. The quantity of metal employed is about 40,000 cwt., and the value of the articles annually produced is £250,000. In the *lead*-works the quantity of metal employed is 65,000 cwt., and the annual value of the goods produced, £100,000. *Tin* is manufactured (principally in Bohemia) to the annual value of £50,000, and zinc to that of £2500. The precious metals, *gold* and *silver*, are principally worked in the larger towns, particularly Vienna and Prague, and the value of the articles annually produced is about £1,700,000. In addition to this a considerable amount of gold and silver is annually taken up by the mints. The mixed metals are also made and manufactured to a considerable extent, as brass, bell metal, gun metal, pinchbeck, &c.

The *glass* manufacture has its greatest development in Bohemia, where there are not only the greatest number of works (35 in Northern and 85 in Southern Bohemia), but the wares are also of

very superior quality. Their annual value is about £1,000,000. Except in Styria and Moravia there is little glass made in other parts of the country, and that only of the commoner sorts. The manufacture of mirrors is also extensively carried on in Bohemia and some other parts. Bohemia and Moravia are likewise distinguished for their earthen and porcelain wares. The preparation of *chemical stuffs* has been of late years greatly extended, and is now actively carried on. Sulphuric and muriatic acids are largely made in Bohemia, Lower Austria, and Silesia; pharmaceutical preparations and perfumes are made chiefly in Vienna, and dye-stuffs in Lower Austria and Bohemia. The manufacture of *wooden articles* is wide-spread over the country, and affords employment to a great number of persons. The smaller articles, particularly children's toys, are largely made by the peasantry in the mountainous and rural districts, particularly in Tyrol, Salzburg, Upper Austria, and Bohemia. Furniture, waggons, and carriages are made in Vienna and other large towns. There are also several establishments for the manufacture of railway carriages in Vienna and Prague.

The manufacture of mathematical, optical, and surgical instruments, and of physical and chemical apparatus, has of late years risen rapidly into importance, particularly in Vienna and Prague, and now these are to be found among the exports to other countries. Austria is also distinguished for the manufacture of musical instruments, particularly pianos and organs, but also for other stringed and wind instruments. Clock or watch making is not very extensively carried on.

The *leather* manufacture forms an important branch of industry, the value of the goods annually produced being estimated at not less than £10,000,000. It is principally carried on in Lower Austria, Bohemia, Moravia, Galicia, Transylvania, and Hungary. Vienna and Prague are the great centres of the boot and shoe trade, and the gloves made in these towns are considered little inferior to those of France. Saddlery is also largely carried on in these towns, and in Pesth.

Paper-making has of late made considerable progress in Austria. There are 70 paper machines and 193 paper mills in operation, 20 of the former and 100 of the latter being in Bohemia. The rest are mostly in Lower Austria, Styria, and Fiume. Painting, lithographing, engraving, and map making, are actively carried on in Vienna and some of the other large towns. There are 44 printing and 78 lithographic establishments in Vienna alone.

Austria is noted for its *beer*, particularly that of Vienna and Bohemia. There are about 3200 breweries in the country, of which more than 1000 are in Bohemia. The largest establishments, however, are in Lower Austria, in the neighbourhood of Vienna. The annual quantity of beer made is estimated at about 186,000,000 gallons. Brandy is made largely in Hungary, Galicia, and Buckowina, and to a less extent in Bohemia, Moravia, and Lower Austria. Rosoglio, maraschino, and other liqueurs, are made in Dalmatia and Moravia.

The manufacture of *sugar* from beet-root is in a very flourishing state, and is rapidly extending. In 1857 there were in Austria Proper 91 sugar-works, consuming 8,300,000 cwt. of beet, which amounts were in 1870 raised to 190 and 24,834,646 respectively. In Bohemia alone there were 126 works, consuming 15,279,000 cwt. of beet. Of the other works, Moravia possessed 45, Silesia 10, Lower Austria 6, Galicia 5. This manufacture is also carried on to some extent in Hungary and Transylvania.

The manufacture as well as the growth of *tobacco* is a government monopoly. There are 22 establishments for the manufacture of tobacco and cigars, employing about 20,000 workpeople. Of these there are 5 in Lower Austria, 3 in Galicia, 2 in Moravia, 2 in Tyrol, and 4 in Hungary. The largest are those of Hainburg in Lower Austria (where about one-sixth of the whole is manufactured), Fürstenfeld in Styria, and Sedler in Bohemia. About 70,000,000 lb of tobacco are manufactured annually.

The annual value of the industrial products of Austria is estimated at not less than £130,000,000, of which 33 per cent. falls to the eastern, and 67 per cent. to the western half of the country. Among the crown-lands, 18 per cent. belongs to Bohemia alone, 15 to Lower Austria, 15 to Hungary, 6 to Transylvania and the other Hungarian crown-lands, 11 to Galicia and Buckowina 10 to Moravia, 6 to Tyrol, 4 to Styria, and 4 to Upper Austria.

Commerce. Austria is not favourably situated for commerce on account of its inland position, its small extent of sea-coast, and the mountainous character of much of its surface. Its trade was also formerly very much hampered by high duties and restrictions of various kinds. These, however, have now been very much modified or removed, and its trade has in consequence rapidly improved. Much has been done, too, in the way of making and improving the roads, opening mountain passes, constructing railways, and establishing lines of steamers. In 1874 there were 9530 miles of railway in operation, of which 5755 were in Austria and 3775 in Hungary. Besides these there were about 2000 miles in course of construction. There are also 59,770 miles of highways, of which 70 per cent. are in Austria and 30 in Hungary. Bohemia, in particular, is distinguished for the number and excellence of its roads. The river Danube is navigable for steamers for its entire length in the country—from Passau to Orsova. Many of its affluents are also navigable for a considerable length, particularly the Theiss, Drave, and Save. The Danube Steam Company possesses 155 steamers, of 13,946 horse-power, and 495 towed boats. There are also steamers on a number of the larger lakes. Altogether, Austria possesses 4240 miles of navigable river and canal communication, of which the greater part (60 per cent.) is in Hungary.

The principal seaports of Austria are Trieste and Fiume, at the head of the Adriatic, the former in the Maritime crown-land, the latter in that of Croatia. The number of vessels that entered the port of Trieste in 1870 was—sailing vessels, laden, 5332; in ballast, 898; total tonnage, 407,606; value of imports, £4,673,170: steamers, laden, 924; in ballast, 900; total tonnage, 552,497; value of imports, £12,586,950. The number of vessels that left was—sailing vessels, laden, 4409; in ballast, 1794; total tonnage, 441,601; value of exports, £3,325,400: steamers, laden, 920; in ballast, 900; total tonnage, 571,175; value of exports, £6,716,940. Trieste is the seat of the Austrian Lloyds' Company, which trades principally with the eastern ports of the Mediterranean, Galacz, Sinope, Smyrna, Beirout, Alexandria, &c. They own 68 steam vessels. The number of vessels that entered the port of Fiume in 1870 was—sailing vessels, laden, 1530; in ballast, 270; total tonnage, 77,499; value of imports, £519,820: steamers, laden, 229; in ballast, 17; total tonnage, 52,671; value of imports, £174,720. The number of vessels that left was—sailing vessels, laden, 1180; in ballast, 622; total tonnage, 88,781; value of exports, £366,790: steamers, laden, 245; in ballast, 1; total tonnage, 52,671; value of exports, £94,340.

The commercial navy of Austria in 1870 comprised 83 steam vessels, of 47,242 tons burden, having 2352 men; 566 large sailing vessels, trading with foreign countries, of 255,930 tons burden, having 5939 men; and 2487 coasting vessels, of 555,318 tons burden, having 7588 men. Besides these, there were 4717 smaller vessels, with 14,475 tons and 12,305 men, employed as lighters, in fishing, &c. The number of trading vessels that entered and left the various ports in 1870 was—entered, sailing vessels, Austrian, laden, 17,564 (tonnage, 486,745); in ballast, 9727 (tonnage, 270,887); foreign, laden, 4360 (tonnage, 263,942); in ballast, 2793 (tonnage, 184,760): steamers, Austrian, laden, 4964 (tonnage, 1,676,095); in ballast, 2597 (tonnage, 409,480); foreign, laden, 179 (tonnage, 138,032); in ballast, 12 (tonnage, 7847). Left—sailing vessels, Austrian, laden, 17,204 (tonnage, 468,093); in ballast, 10,308 (tonnage, 290,531); foreign, laden, 5705 (tonnage, 384,019); in ballast, 1976 (tonnage, 103,995): steamers, Austrian, laden, 4160 (tonnage, 1,403,865); in ballast, 3397 (tonnage, 678,512); foreign, laden, 160 (tonnage, 143,100); in ballast, 32 (tonnage, 21,790). Total entered—Austrian vessels, 34,852 (tonnage, 2,843,207); foreign, 7344 (tonnage, 594,581): left—Austrian, 35,069 (tonnage, 2,841,001); foreign, 7271 (tonnage, 652,904). The total value of the imports was £16,630,150; of the exports, £13,052,250—£7,098,180 of the former, and £3,578,810 of the latter, being in foreign vessels. The principal foreign trade is carried on with Italy, Greece, Turkey, England, Holland, Norway and Sweden, North Germany, Denmark, and North America. The number of vessels belonging to the principal foreign states that entered and left the various ports in 1870, was as follows:—

	Entered.			Left.		
	Vessels.	Tonnage.	Value of Cargoes.	Vessels.	Tonnage.	Value of Cargoes.
			£			£
Italian	3557	185,142	1,623,730	4568	301,781	1,539,910
Greek	383	31,511	448,140	313	35,415	303,260
Turkish . ..	234	13,367	156,940	126	12,455	132,510
British	213	137,330	3,724,810	175	138,462	1,237,390
Dutch	41	8,795	234,710	35	8,770	112,160
Swedish and Norwegian	30	7,471	264,870	23	8,762	71,980

The principal imports, with their values, were—coffee, £805,370; sugar, £218,950; tobacco, in leaf, £417,670; ditto, manufactured, £457,520; wheat, £311,500; maize, £331,060; flour, £431,840; olive oil, £778,890; iron, raw and wrought, £1,210,570; raw cotton, £1,855,210; cotton yarn, £303,130; cotton goods, £1,375,390; linen goods, £226,470; wool, £266,270; woollen goods, £252,900; machines, £216,010. The principal exports were—coffee, £336,610; sugar, £381,090; manufactured tobacco, £370,610; wheat, £244,410; maize, £434,980; flour, £938,730; olive oil, £614,640; spirits of wine, £334,620; barrel staves, £517,520; building stones, £307,040; raw cotton, £293,750; cotton goods, £2,030,060; wool, £109,490; woollen goods, £249,738; articles of clothing, £212,540; paper, £256,070.

As might be expected from its natural position, the overland foreign trade of Austria is more important than its sea traffic. While the latter amounted to £29,682,400, the former was no less than £55,039,034 (imports, £27,890,181; exports, £27,148,853). Of the overland trade about 74 per cent. is with Germany, 14 with

Turkey, 6¼ with Italy, 5¼ with Russia, and rather more than ½ with Switzerland. It includes colonial goods, agricultural and garden produce, animals and animal produce, the produce of the mines and manufactures, chemical products, machines, scientific instruments, wine, beer, brandy, &c. Besides these, there is a considerable transit trade through the country, chiefly from the seaports and the eastern borders, towards the north and north-west. It is estimated at about £12,000,000.

The internal trade consists chiefly of the exchange of the products of different parts of the country, more particularly of the agricultural products of the east with the industrial products of the west. Important markets are held at fixed times in the principal towns for the different kinds of produce. Vienna, as being the capital and the seat of so many different branches of industry, and as having ready means of communication with all parts of the country, is the principal seat both of the home and of the foreign trade, and the great resort of merchants and capitalists.

Austria possesses a number of banks, the principal of which are—the National Bank, founded in 1816, and having an active capital of £9,000,000; the Austrian Land-Credit Institute, founded 1864, active capital, £960,000; the Austrian Trade and Manufactures Credit Institute, founded 1855, active capital, £4,000,000; the Anglo-Austrian Bank, founded 1863, active capital, £1,704,500; the Union Bank, founded 1870, active capital, £1,200,000; the Franco-Austrian Bank, founded 1869, active capital, £800,000; the Lower Austrian Discount Company, founded 1853, active capital, £700,000. The National Bank is the only company authorised to issue notes. There are also a number of savings banks and loan institutions of various kinds, as well as numerous societies formed with the view of furthering in various ways industry and commerce. In 1871 there were 3504 post-offices in Austria, and 1638 in Hungary; the number of private letters that passed through the former in that year was 125,614,538, and through the latter, 37,368,139; of newspapers through the former, 51,780,909, and through the latter, 22,303,771. There were also throughout the country 1081 telegraph stations, and 22,536 miles of lines transmitting upwards of 5,000,000 messages during that year.

Government. The head of the Austro-Hungarian monarchy is the emperor and king, who is also the head of the army and of the executive. The succession is hereditary, in the order of primogeniture, in the male line of the house of Hapsburg-Lothringen, or Lorraine; and failing this, in the female line. The monarchy comprises two distinct states—a German or Cisleithan, commonly called Austria, and a Magyar or Transleithan, usually termed Hungary. Each of these has its own parliament, ministers, and government; while the army and navy and foreign relations are common. These are under the direction of a controlling body known as the Delegations, consisting of sixty members for each state, two-thirds being elected by the Lower House, and one-third by the Upper House of each of the parliamentary bodies. They usually sit and vote in two chambers—one for Austria, the other for Hungary; but in the event of disagreement on any question, they meet together, and without further deliberation give their final votes, and the decision thus arrived at is binding on the whole empire. Their resolutions require neither the approval nor the confirmation of the representative assemblies by which they are chosen, but only imperial assent. The executive is vested in three departments—(1), A ministry of foreign affairs; (2), a ministry of war; and (3), a ministry of finance. These are responsible to the Delegations. The Reichsrath, or Parliament of Austria, consists of an Upper and a Lower House. The former, the House of Lords, is composed—(1), of princes of the imperial house who are of age (14 in 1874); (2), of the heads of noble houses of high rank, in whom the dignity is hereditary (56); (3), of the archbishops (10) and of bishops with the rank of princes (7); and (4), of life members nominated by the emperor on account of distinguished services (102). The Lower House, or House of Representatives, is composed of 353 members, elected to represent the different crown-lands by all citizens who are of age and possessed of a small property qualification. The emperor annually convokes the Reichsrath, and nominates the presidents and vice-presidents of each division out of the members. The business of the Reichsrath embraces all matters of legislation relating to laws, duties, and interests, except such as are specially excluded as belonging to other departments. It also takes up matters connected with trade, commerce, and finance, the post-office, railways, telegraphs, customs, the mint, raising of new loans, imposing of new taxes, budgets, matters relating to military service, &c. The members of either House have the right to propose new laws on matters within their province; but the consent of both Houses, as well as the sanction of the emperor, is required to render them valid. The executive is vested in the president and ministries of the interior, religion and education, finance, commerce, agriculture, national defence, and justice. The ministers form also the Ministerial Council, which is presided over by the emperor or a minister-president.

In addition to the Reichsrath, there are seventeen provincial diets established in different districts of the country for the direction and regulation of local matters, taxation, education, religion, public works, charitable institutions, industry, trade, &c. Each diet is composed of the archbishops and bishops of the Roman Catholic and Greek Catholic Churches, of the rectors of the universities, and of representatives of the great landed estates, of the towns, of chambers of industry and commerce, and of rural communes. The number of members varies according to the size and importance of the districts—from 20 or 30 up to 100 for Moravia, 151 for Galicia, and 241 for Bohemia.

The Hungarian Parliament or Reichstag consists of an Upper and a Lower House,—the former known as the House of Magnates, the latter as the House of Representatives. The Upper House, in 1873, consisted of 3 princes of the reigning house, having estates in the kingdom, 31 archbishops and bishops of the Roman Catholic and Greek Churches, and 381 high officials and peers of the kingdom. The Lower House is composed of representatives elected for three years by citizens of age who pay a certain amount of direct taxes. The number of representatives, in 1873, was 444, of whom 334 represented the counties, rural districts, and towns of Hungary; 75 represented Transylvania; and 35 Croatia and Slavonia. The president and vice-president of the House of Magnates are nominated by the king from among the members; and the president and two vice-presidents of the House of Representatives are elected by the members. The sovereign, though emperor of Austria, is styled "king" in all public documents. The executive is vested in a president and ministries of national defence, the court, finance, interior, religion and education, justice, public works, agriculture, industry and commerce, and for Croatia and Slavonia.

Finance. The revenue and expenditure are presented in three distinct budgets:—(1), That of the Delegations for the whole empire; (2), that of the Austrian Reichsrath for Austria; and (3), that of the Hungarian Reichstag for Hungary. By an arrangement of 1868 Austria pays 70 per cent., and Hungary 30 per cent., towards the common expenditure of the empire. The total expenditure for the whole empire, in 1873, was estimated as follows:—

		Ordinary.	Extraordinary.	Total.
1. Ministry of Foreign Affairs		£424,629	£11,181	£435,810
2. Ministry of War	Army	8,909,356	989,962	9,899,318
	Navy	831,427	182,654	1,014,081
3. Ministry of Finance		192,098	105	192,203
4. Board of Control		10,409	...	10,409
		£10,367,919	£1,183,902	£11,551,821

The estimated Revenue for the same period was as follows:—

Ministry of Foreign Affairs	£69,750	
" War	510,141	
" Finance	258	
Board of Control	83	
		£580,232
	Carry forward,	£580,232

Brought forward,	£580,232
Customs Duties	1,555,600
Payments by Hungary on account of Military Frontiers	188,319
Share of Expenditure falling to Austria (70 p.c.)	6,459,368
,, ,, ,, Hungary (30 p.c.)	2,768,302
	£11,551,821

The budget of Austria Proper for 1873 was as follows:—

Receipts.

Direct Taxes	£9,034,400
Customs Duties	2,314,100
Duties on Articles of Consumption	5,876,230
Salt Monopoly	1,872,000
Tobacco Monopoly	5,812,600
Stamps	1,400,000
Judicial Fees	3,360,000
State Lottery	1,526,000
Octroi	274,300
State Property and Mint	177,748

Miscellaneous	650,264
	£23,220,939

The budget for 1874 gives the revenue as £22,402,790, and the expenditure as £25,673,382, being a deficit of £3,270,592.

Though the Austrian budget for 1873 presents a surplus, there had for many years previously been a large annual deficit, amounting in some years to £6,000,000 or £7,000,000; and the two subsequent years also show a considerable deficiency. Consequently, the public debt has been rapidly increasing. In 1815 the national debt amounted to £82,500,000, in 1830 to £108,000,000, in 1848 to £125,000,000, in 1857 to £239,000,000, in 1866 to £291,000,000, and in 1874 to £323,800,000, of which £264,000,000 was funded, £22,200,000 redeemable, and £37,600,000 floating debt. By the cession of the Lombardo-Venetian provinces in 1866, Austria was relieved of £3,500,000 of debt affecting those territories. The kingdom of Hungary had also at the end of 1873 a debt of £48,871,783.

Army. Austria is said to have "during the last few years made greater sacrifices to improve the efficiency of her army and obtained greater results than any other nation in Europe. Her military educational establishments and system of training, both elementary and professional, for officers and men, are of a very high order" (Captain W. S. Cooke *On the Armed Strength of Austria*, 1873). A new scheme of army organisation was brought into operation in 1869, by which the military forces of the whole empire are divided into the standing army with its reserve, the Landwehr, the Ersatz-reserve, and the Landsturm. The standing army is maintained for the defence of the empire against a foreign foe, and for the preservation of order and security at home. The Landwehr is intended to support the standing army in time of war and for home defence. The Ersatz-reserve is composed of a certain class of conscripts who are destined to fill up the ranks of the standing army in time of war, but in peace remain on permanent furlough. The Landsturm is made up of volunteers who do not belong either to the standing army, the navy, or the Landwehr. It is called out and organised to the extent required when the country is threatened by a hostile invasion, and is intended to support the standing army and Landwehr. Military service is compulsory on all citizens capable of bearing arms. The term of service lasts for twelve years—three in the standing army, seven in the reserve, and two in the Landwehr. The strength of the army in peace is fixed at 252,000 men, to be raised during war to 800,000, of which Austria has to furnish 457,012, and Hungary 342,988. It is composed of 80 regiments of infantry, 41 regiments of cavalry, 13 regiments of artillery, 2 regiments of engineers, 1 regiment pioneers, and other troops. (See ARMY, vol. ii. p. 604.) **Navy.** The navy was in 1874 composed of 47 steam-vessels, of 96,700 tons burden and 16,635 horse-power, carrying 395 guns; 17 sailing vessels, of 11,800 tons; and 6 steam tenders, of 1260 tons burden and 366 horse-power. The number of seamen in peace, 5782; in war, 11,532. The naval stations are Pola and Trieste.

History. The present empire of Austria took its rise in a margraviate founded by Charlemagne, towards the close of the 8th century, in that fertile tract of country lying along the southern bank of the Danube to the east of the River Enns, and now included in Lower Austria. It was called *Ostreich* or *Oesterreich*, the eastern country, from its position relative to the rest of Germany. It continued to be ruled by margraves (Ger. *Markgraf*, lord of the marches) for several centuries, down to the year 1156, when the territory west of the Enns was added to it, and it was raised to a duchy. It subsequently received further accessions of territory, and in 1453 was made an archduchy.

The country of the present archduchy of Austria was in early times inhabited by the Taurisci, a Celtic race, who were afterwards better known as the Norici. They were conquered by the Romans in 14 B.C.; and thereafter a portion of what is now Lower Austria and Styria, together with the municipal city of *Vindobona*, now Vienna, and even then a place of considerable importance, was formed into the province of Pannonia; and the rest of Lower Austria and Styria, together with Carinthia and a part of Carniola, into that of Noricum. Tyrol was included in Rhætia, while north of the Danube, and extending to the borders of Bohemia and Moravia, were the territories of the Marcomanni and the Quadi. These were not unfrequently troublesome to the Romans; and during the greater part of the reign of Marcus Aurelius, from 169 to 180 A.D., they maintained with varying success a harassing war against them. In 174 the Roman army was so nearly cut off by the Quadi that its safety was attributed to a miracle. The emperor died at Vindobona when on an expedition against those troublesome neighbours, and his successor, Commodus, was glad to make peace with them. On the decline of the imperial power these Roman provinces became a prey to the incursions of barbaric tribes.

During the 5th and 6th centuries the country was successively occupied by the Boii, Vandals, Heruli, Rugii, Goths, Huns, Lombards, and Avari. About 568, after the Lombards had settled in Upper Italy, the River Enns became the boundary between the Bajuvarii, a people of German origin, and the Avari, who had come from the east. In 788 the Avari crossed the Enns and attacked Bavaria, but were subsequently driven back by Charlemagne, and forced to retreat as far as the Raab, their country from the Enns to that river being then made a part of Germany. It was taken by the Hungarians in 900, but was again annexed to Germany in 955 by Otho I. In 983 the emperor appointed Leopold I., of Babenberg or Bamberg, margrave of Austria, and his dynasty ruled the country for 263 years. He died in 994, and was succeeded by his son, Henry I., who governed till 1018. In 1156 Austria received an accession of territory west of the Enns, and was raised to a duchy by the Emperor Frederick I. The first duke was Henry Jasomirgott, who took part in the second crusade. He removed the ducal residence to Vienna, and began the building of St Stephen's cathedral. His successor, Leopold V., in 1192, obtained Styria as an addition to his territory, and Frederick II. received possession of Carniola. Frederick, in the latter years of his life, contemplated the erection of Austria into a kingdom, but his sudden death in a battle against the Magyars, in 1246, put an end to the project, and with him the line became extinct.

The Emperor Frederick II. now declared Austria and Styria to have lapsed to the imperial crown, and appointed a lieutenant to govern them on the part of the empire. But claims to the succession were brought forward by descendants of the female branch of the Babenberg line; and after various contests Ottocar, son of the king of Bohemia, gained possession about 1252 of the duchies of Austria and Styria. In 1269 he succeeded to Carinthia, a part of Carniola and Friuli; but he lost all by refusing to acknowledge the Emperor Rudolph of Hapsburg, and eventually fell in battle in an attempt to recover them in 1278.

Hapsburg dynasty.

The emperor now took possession of the country, and appointed his eldest son governor; but subsequently, in 1282, having obtained the sanction of the electors of the empire to the act, he conferred the duchies of Austria and Styria, with the province of Carinthia, on his sons Albert and Rudolph, and thus introduced the Hapsburg dynasty. The brothers transferred Carinthia to Meinhard, count of Tyrol; and in 1283 Albert became sole possessor of Austria, Styria, and Carniola. He increased his possessions considerably by wars with his neighbours, but was murdered at Rheinfelden in 1308, when on an expedition against the Swiss, by his nephew, John of Swabia, whom he had deprived of his hereditary possessions. He was succeeded by his five sons, Frederick, Leopold, Henry, Albert, and Otto. In 1314 Frederick, the eldest, was set up by a party as emperor in opposition to Louis, duke of Bavaria, but was defeated and taken prisoner by his rival in 1322. In 1315 Duke Leopold was defeated in an attempt to recover the forest towns of Switzerland which had revolted from his father. Leopold died in 1326, Henry in 1327, and Frederick in 1330. The two surviving brothers then made peace with the Emperor Louis, and in 1335 they acquired Carinthia by inheritance. On the death of Otto in 1339 Albert became sole ruler. He died in 1358. His son and successor, Rudolph II., finished the church of St Stephen's and founded the university of Vienna, dying childless in 1365. He was succeeded by his two brothers, Albert III. and Leopold III., who in 1379 divided their possessions between them, the former taking the duchy of Austria, the latter Styria and other parts. Leopold fell at Sempach in 1386, but his descendants continued to rule in Styria. Albert acquired Tyrol and some other districts, and died in 1395. He was succeeded by his son, Albert IV., who was poisoned at Znaim in 1404, when on an expedition against Procopius, count of Moravia. Albert V. succeeded his father, and having married the daughter of the Emperor Sigismund, he obtained the thrones of Hungary and Bohemia, and became emperor (Albert II.) in 1438. He died the following year, and was succeeded by his posthumous son Ladislaus, who died without issue in 1457. The Austrian branch of the family thus became extinct, and was succeeded by that of Styria. The crowns of Hungary and Bohemia passed for a time into other hands.

The possession of Austria, which in 1453 had been raised to an archduchy, was for some years a subject of dispute between the Emperor Frederick III. and his brothers, but at length, on the death of Albert in 1463, the emperor obtained sole possession. His son Maximilian, by marrying the daughter of Charles the Bold, acquired the Netherlands in 1477, but on the death of his father in 1493 he succeeded him as emperor, and transferred the government of the Netherlands to his son Philip. He added Tyrol and some parts of Bavaria to his paternal possessions, and made some advances towards the recovery of Hungary and Bohemia. His son Philip, by his marriage with Johanna, daughter of Ferdinand and Isabella, acquired a right to the crown of Spain, but died in 1506. Maximilian died in 1519, and was succeeded by his grandson Charles (son of Philip), who two years before had obtained the Spanish crown, and was now made emperor under the title of Charles V. By treaties dated 1521 and 1524, Charles resigned all his hereditary possessions in Germany, except the Netherlands, to his brother Ferdinand. The latter, by his marriage with Anna, sister of the king of Hungary, acquired right to the kingdoms of Hungary and Bohemia, together with Moravia, Silesia, and Lausatia. His right to Hungary, however, was contested by John Zapolya, waywode of Transylvania, who was elected by a party of the nobles, and was crowned king in 1527. Being unable to cope single-handed with Ferdinand, John sought the aid of the sultan, Soliman II., who in 1529 advanced with a large army to the very gates of Vienna; but after several ineffectual attempts to take the city he raised the siege and returned to Buda. At length, in 1535 an agreement was come to, in terms of which John was allowed to retain the title of king, together with half of Hungary, but his descendants were to be entitled to Transylvania only. John died in 1540, but the people of Lower Hungary were opposed to Ferdinand, and set up the son of their late king against him. In the struggle which ensued the aid of the Turks was again invoked, and the result was that Ferdinand had to agree to pay an annual sum of 30,000 ducats to the sultan for this part of Hungary. Ferdinand was also under the necessity of surrendering Würtemberg to Duke Ulrich, on condition of its remaining a fief of Austria and reverting to that country on the extinction of the male line. Notwithstanding this, the possessions of the German line of the house of Austria at this time are estimated at 114,000 square miles. On the abdication of Charles V. in 1556, Ferdinand succeeded to the imperial throne. He died in 1564, leaving directions for the division of his possessions among his three sons. The eldest, Maximilian II., received the imperial crown, together with Austria, Hungary, and Bohemia; the second, Ferdinand, obtained Tyrol and Lower Austria; and the third, Charles, was made master of Styria, Carinthia, Carniola, and Görtz. In 1556 the sultan Soliman again marched at the head of a great army into Hungary, but met with a very determined resistance at Szigeth, before which town he was suddenly cut off by apoplexy.

Peace was concluded with his successor, and in 1572 Maximilian caused his eldest son Rudolph to be crowned king of Hungary. He was afterwards crowned king of Bohemia, and was also elected king of the Romans. Maximilian died in 1576, and was succeeded by Rudolph on the imperial throne. This monarch was little fitted to rule, and left the management of affairs very much to others. He was entirely under the power of the Jesuits, set at nought the ancient laws of the country, and persecuted the Protestants. The latter, under Bocskay, revolted in 1604, and having secured the aid of the sultan, gained repeated victories over the imperial troops, compelling Rudolph to give them terms of peace in 1606. During this reign the possessions of the Archduke Ferdinand of Tyrol reverted to the two other lines; while in 1608 Rudolph was compelled to cede Hungary, and in 1611 Bohemia and Austria, to his brother Matthias, who on the death of Rudolph in 1612 was crowned emperor. His reign was full of promise, but unfortunately it was only of short duration. Being an old man and childless, he chose as his successor his cousin Ferdinand, archduke of Styria, whom he caused to be crowned king of Bohemia in 1616, and of Hungary in 1618. He died the following year, when Ferdinand became emperor.

irty
ars War.

Before the death of Matthias, the memorable struggle between Roman Catholicism and Protestantism, known as the *Thirty Years' War* (1618 to 1648), had commenced. It originated in an insurrection of the Protestants of Bohemia, who renounced their allegiance to Ferdinand and chose for their king the elector palatine Frederick V. Frederick was supported by all the Protestant princes except the elector of Saxony, while Ferdinand was assisted by the king of Spain and the other Catholic princes. At first success attended the arms of the insurgents, who repeatedly routed the imperial troops, and even laid siege to Vienna. But the Duke Maximilian of Bavaria, coming to the assistance of the imperialists at the head of a well-appointed army, totally defeated Frederick at the White Hill near Prague (8th November 1620). The following day Prague opened its gates to the conqueror, and in a short time the whole country was reduced to subjection, and the territories of the elector palatine divided among the allies. The war might have ended here had Ferdinand adopted a conciliatory policy, but impelled by revenge and fanatical zeal he adopted an opposite course, and instituted against the Protestants a severe persecution. They were thus again compelled to take up arms, and in 1625 Christian IV., king of Denmark, supported by subsidies from England, put himself at their head. He was subsequently joined by Count Mansfeld and Christian of Brunswick, while opposed to him were Wallenstein and Tilly at the head of two powerful armies. In April 1626 Mansfeld was defeated by Wallenstein at Dessau, and a few months later Tilly vanquished the Danish king at Lutter. The victorious armies afterwards marched into Denmark, and the king was compelled to conclude a humiliating peace at Lübeck in 1629. The Protestants were now awed into submission, and Ferdinand was emboldened to carry out to still greater lengths his policy of suppression. Aiming at the total extirpation of Protestant doctrines throughout his dominions, he revoked all the privileges that had formerly been granted, even such as had previously received his approval. By the so-called *Edict of Restitution*, dated 6th March 1629, he enjoined the restitution of all ecclesiastical property secularised since the peace of Passau, and ordered the Protestants to relinquish to the Catholics all benefices which they had appropriated contrary to the peace of Passau and the Ecclesiastical Reservation.

The Catholic princes themselves were now becoming alarmed at the enormous power which they had contributed to place in the hands of the emperor. They therefore demanded a reduction of the army and the dismissal of Wallenstein, and with these demands the emperor felt himself obliged to comply. But a new champion of the Protestant cause now appeared in the north, in the person of Gustavus Adolphus, king of Sweden. This valiant prince, having received promises of aid from France as well as from England and the United Provinces, suddenly landed an army of 15,000 men at Usedom in June 1630. Pomerania and Mecklenburg were soon conquered by him, and a great part of Brandenburg was overrun by his army. He was unable, however, to relieve the town of Magdeburg, which was besieged by Tilly and taken by assault 20th May 1631, when the most barbarous atrocities were perpetrated upon the unfortunate inhabitants. The elector of Brandenburg and afterwards the elector of Saxony joined Gustavus, and the combined army met the imperialists under Tilly at Breitenfeld, near Leipsic, and defeated them with great slaughter (7th September 1631). The victor now rapidly regained all that had been lost. Again Tilly was beaten at the passage of the River Lech on 5th April 1632, and the following day he died of his wounds. Wallenstein was now recalled and placed at the head of the imperial troops. His name inspired fresh ardour among the soldiery, men flocked to his standard, and he speedily found himself at the head of a very large army. He drove the Saxons out of Bohemia, and afterwards marched to Nuremberg, where Gustavus was entrenched in a strong position. The two armies watched each other for eight weeks, when the king directed an attack against the imperialists, but after a fierce struggle was repulsed. A fortnight later Gustavus moved in the direction of Bavaria, but Wallenstein, instead of following him, marched into Saxony, and thus obliged him to suspend his operations in Bavaria and to set out in pursuit of his opponent. The two armies met at Lützen, where a battle took place on 16th November 1632. The greatest skill and bravery were displayed on both sides, and the issue was long doubtful, but at length victory declared in favour of the Swedes, though dearly purchased with the loss of their brave commander, who fell mortally wounded.

The death of Gustavus was an irreparable loss to the Protestants in Germany. Wallenstein, however, made but little use of the advantages he now possessed, and has even been accused of treacherous designs against the empire. Be this as it may, his enemies at court and in the army were numerous and powerful, and he was at length assassinated by some of his own officers, 25th February 1634. The Protestant cause met with another disaster in the defeat of Bernard of Weimar at Nordlingen on 6th September. On 30th May 1635 Saxony concluded at Prague a treaty of peace with the emperor, in terms of which the Lutherans were freed from the operation of the Edict of Restitution. The other Lutheran princes soon after accepted the like terms; but the Calvinists, who were disliked by both parties, were left to their fate.

Sweden, no longer able to carry on the war as she had done, entered into a treaty with France, resigning the direction of operations to that power, a position of which Richelieu gladly availed himself, as according with his ambitious designs. The war now assumed a new phase, France and Sweden being allied against the empire and the Lutheran states of Germany, aided by Spain. Richelieu's efforts were in great measure directed to humbling the latter power. He sent an army into Spain, and entered into leagues with the dukes of Savoy and Parma and the United Provinces for attacking the Spanish power in Italy and the Netherlands. These projects did not meet with success, and the war was for a time carried into the French territories. In the meantime the Swedes, under General Baner, gained a brilliant victory over the Saxons and imperialists at Wittstock (4th October 1636). The emperor

died on the 15th February 1637, and was succeeded by his son Ferdinand III. The war was carried on for eleven years longer; and the success which at first was with the imperialists, after a time came round to their adversaries, till at length the emperor, pressed on all sides and deserted by his allies, was glad to agree to terms of peace. By the peace of Westphalia, signed 24th October 1648, France acquired Alsace; Sweden got Upper Pomerania, the Isle of Rugen, and some other territory; the sovereignty and independence of the different states was recognised; the Calvinists were placed on the same footing as the Lutherans; and the independence of the United Provinces and the Swiss Confederation was acknowledged.

Ferdinand III. died in 1657, and was succeeded by his son Leopold I. This prince, by his harsh treatment of the Hungarians, drove that people into revolt; and they, being unable to cope with the power of the empire single-handed, called in the aid of the Turks, who, under Kara Mustapha in 1683, besieged Vienna, which was only saved by an army of Poles and Germans under John Sobieski. The imperial army then reduced the whole of Hungary into subjection, and united to it Transylvania, which had been hitherto governed by its own princes; and the whole was declared to be a hereditary kingdom. In 1699 Turkey, after being defeated in several sanguinary engagements by the celebrated general Prince Eugene, was compelled by the peace of Carlowitz to cede to Hungary the country lying between the Danube and the Theiss. Previous to his troubles with Hungary and Turkey, Leopold had lent his aid in 1672 to the Dutch in their struggle against the ambitious designs of France. This was brought to a close by the peace of Nimeguen in 1678; but the conflict broke out afresh the following year, when the English also came forward and contributed largely both in troops and money. The chief scenes of warfare were the Netherlands and the banks of the Rhine. At last in 1697 came the peace of Ryswick, which left the contending parties in nearly the same relative positions as at the beginning of the contest. The allies had, however, the satisfaction of having compelled the French king to stop short in his schemes of aggrandisement.

War of the Succession. The death of Charles II. of Spain in 1700, without leaving issue, led to what is known as the *War of the Succession.* Louis XIV. had married the eldest sister of the late king, but she had by solemn covenant renounced her right to the Spanish crown. The second sister had married the Emperor Leopold, and she had made no such renunciation, but her daughter had, who was married to the elector of Bavaria. Leopold had two sons by a second marriage, and now claimed the crown for the younger of these, on the ground of his mother being an aunt of the deceased king. Intrigues had been carried on by the several parties concerned for some time before the king's death, and he had been induced to make a secret will, in which he named Philip, duke of Anjou, grandson of Louis XIV., as his successor. Leopold, however, was by no means inclined to depart from what he considered his rights, and the other states of Europe looked with jealousy on the prospect of a union of France and Spain under a Bourbon dynasty. An alliance was accordingly formed by Austria with England and Holland against France, with which power on the other hand Bavaria allied herself. The emperor despatched an army into Italy under Prince Eugene, to take possession of the Spanish territories in that country; while the English and Dutch united their forces under Marlborough. The former experienced a good deal of hard fighting, but effected little of consequence, while the latter busied himself in taking one after another of the French strongholds in the Netherlands. At length the two generals combined their forces and met the united army of their enemies at Blenheim. The latter numbered about 56,000 men and occupied a strong position, while the number of the former was about 52,000. The fight commenced by Marlborough leading the right wing against the French, while Eugene with the left wing advanced against the Bavarians. The battle was long and fierce, the assailants being repeatedly driven back by a most terrible fire from the enemy's artillery. At length victory declared for the allied English and Austrian armies (13th August 1704). About 10,000 of the French and Bavarians fell on the field, and nearly 13,000 were made prisoners, among whom was the commander of the French army, Marshal Tallard. The elector of Bavaria was compelled to cross the Rhine with the French, and his territory was occupied by the imperialists. The following year the emperor died, and was succeeded by his eldest son, Joseph. The war was continued with vigour, but for a time nothing of importance was anywhere effected. France now directed her chief attention to the conquest of the Netherlands, and sent into that country a magnificent army under the command of Marshal Villeroi. But this general was no match for Marlborough; and in the battle of Ramillies (23d May 1706) he was totally defeated with a loss of about 13,000 men. Prince Eugene's efforts in Italy were also this year crowned with much success. After a memorable march of more than 200 miles, he suddenly appeared before Turin, which was then closely besieged by the enemy. Having effected a junction with the duke of Savoy, he attacked the French lines (7th September), and though repeatedly driven back, at length succeeded in totally routing the enemy. The French general, Count Marsin, was wounded, taken prisoner, and died the following day. The French power in Northern Italy was thus shattered, and soon after both French and Spaniards were driven out of the country. The like success attended the efforts of Marlborough in the Netherlands, where he took possession of every place of note. After Eugene had settled affairs in Italy, he again formed a junction with Marlborough in the Netherlands, and on 11th June 1708 they attacked and routed the French under Vendôme at Oudenarde. France now made overtures for peace; but these being rejected, she sent a new army into the field, under the command of Marshal Villars. He was attacked by the two victorious generals in his entrenchments at Malplaquet (11th September 1709) and totally defeated. France again made proposals for peace, but these meeting with no better success, the war was continued. The emperor died on 17th April 1711, and his successor being his brother, the Archduke Charles, who laid claim to the Spanish crown, this event contributed not a little to restore peace. The prospect of the union on one head of the crowns of Austria and Spain did not accord with the views of those who had been hitherto supporting the claims of Austria, and the transfer of Spain to a grandson of Louis XIV. appeared to them the less dangerous alternative of the two. This, joined to the change of ministry in England, and the removal of Marlborough from the command, together with the impatience of the Dutch under so long and so burdensome a war, led to the peace of Utrecht, which was signed 11th April 1713. Austria continued the war for some time longer, but the next year agreed to substantially the same terms at Baden. By this treaty France engaged that the crowns of France and Spain should never be united, and that no part of the Spanish Netherlands should ever be transferred to her; she also ceded to England Nova Scotia, Newfoundland, Hudson's Bay, and St Kitt's, and agreed to destroy the fortifications of Dunkirk; Spain gave up her possessions in the Netherlands and in Italy to Austria (who, on her part, renounced her claim to the Spanish

succession), and ceded Gibraltar and Minorca to England; the Dutch received a small accession of territory; and the duke of Savoy obtained Sicily, with the title of king—afterwards (1720) exchanged for the island of Sardinia. The Austrian monarchy now embraced about 190,000 square miles of territory, with nearly 29,000,000 of inhabitants. Its annual revenue was between 13,000,000 and 14,000,000 florins, and its army consisted of 130,000 men.

Austria next became involved in a war with the Turks, and in 1716 Prince Eugene set out at the head of an army against them. The result was a series of splendid successes, which led to a peace signed at Passarowitz (1718), by which Austria received a considerable accession of territory. Disaffection still continued to subsist between Spain and Austria, which led to repeated negotiations on the part of the other powers to preserve peace. Charles, being without heirs-male, was desirous of securing the succession to his eldest daughter, Maria Theresa, and with this view he framed the celebrated Pragmatic Sanction, and it became his great object to get the assent of the other powers to this arrangement. England and almost all the other powers, except France, Spain, and Sardinia, acceded to it in 1731. In 1733 the emperor became involved in a war with France on behalf of Augustus III. of Saxony, who had been elected king of Poland. France supported the claims of Stanislaus Leczinski, and received the aid of Spain and Sardinia. The war was carried on principally in Italy, where Austria was driven out of most of her possessions, and was glad to sue for peace. By this treaty Augustus was confirmed on the throne of Poland; but Austria was obliged to cede to Stanislaus the duchies of Lorraine and Bar, to be afterwards transferred to France; Don Carlos was placed on the throne of the Two Sicilies, and the grand duchy of Tuscany was bestowed on the duke of Lorraine, the emperor receiving as compensation Parma and Placentia; and France, and afterwards Spain and Sardinia, acceded to the Pragmatic Sanction. War again broke out with the Turks, and Prince Eugene being now no more, the Austrians were repeatedly beaten and expelled from one stronghold after another, till, by the peace of Belgrade (1739), the emperor was compelled to yield up almost all that the arms of Eugene had formerly gained for him. The emperor died on the 20th October 1740, and his eldest daughter, Maria Theresa, who was married to the duke of Lorraine or Lothringen (afterwards archduke of Tuscany), assumed the government. Immediately counter-claims were advanced on all sides. The elector of Bavaria claimed to be rightful heir to the kingdom of Bohemia; the elector of Saxony and king of Poland, and also the king of Spain, claimed the entire succession; the king of Sardinia laid claim to the duchy of Milan, and Frederick II. of Prussia to the province of Silesia. France espoused the cause of Bavaria, while England alone came forward to the assistance of the queen, and the Hungarians, now united and loyal, willingly recruited her armies. Aided by France and Saxony, the elector of Bavaria took possession of Bohemia, and was proclaimed king in 1741, and the following year he was elected emperor under the title of Charles VII. The king of Prussia marched suddenly into Silesia and took possession of that country. The elector of Bavaria, aided by French troops, next invaded Austria, and even threatened Vienna. The queen fled to Presburg and convoked the Hungarian diet. She appeared in the midst of the assembly with her infant son Joseph in her arms, and appealed to them for protection and help. A burst of enthusiasm followed, and a powerful Hungarian army was speedily at her service. The French and Bavarians were soon driven out of the archduchy. A battle was fought between the Austrians under the prince of Lorraine and the Prussians under Frederick, at Czaslau (17th May 1742), in which the former were defeated, and this was followed by the peace of Breslau (11th June), by which Prussia acquired possession of Upper and Lower Silesia (excepting the towns of Troppau and Jägerndorf, and the mountains of Silesia) and the county of Glatz. Austria now turned her arms against the French and Bavarians, the former of whom were driven out of the country. In 1744 the king of Prussia, jealous of the success attending the Austrians, again took the field against them in support of the emperor. He marched into Bohemia and took Prague, but subsequently was forced to retreat; and the death of the emperor Charles on 20th January 1745 changed the aspect of affairs. Maria Theresa's husband was in September elected emperor under the title of Francis I., and after some more fighting, a peace was concluded with Prussia at Dresden, by which the king was confirmed in the possession of Silesia. The war with France was prosecuted for some time longer in the Netherlands and in Italy with varying success, but ultimately peace was concluded at Aix-la-Chapelle, in October 1748. Austria gave up the duchies of Parma, Placentia, and Guastalla to Don Philip, son of the king of Spain, and several districts of Milan to Sardinia; Prussia was confirmed in the possession of Silesia and Glatz; while Maria Theresa was recognised as rightful monarch of Austria. After having acquired peace, and been thus confirmed in her possessions, her great desire was to recover Silesia from Frederick, whose conduct towards her had sunk deep into her heart. She directed her attention to strengthening and improving her army, and to forming alliances with the other states against the Prussian king, particularly with Russia and Saxony. In 1755 war broke out in North America between France and England, and in view of its becoming more general England solicited the aid of Austria, but without success. This naturally led to a union between England and Prussia, while France allied herself with Austria and Russia.

Seven Years' War.

In July 1756, Frederick despatched a messenger to Vienna to ascertain the meaning of the large forces assembled in Bohemia and Moravia. Receiving an evasive answer, he at once marched an army of 60,000 men into Saxony, took Dresden, and made himself master of the country, the Saxon army of only about 17,000 men being shut up in a strong position, but ill-provisioned, between Pirna and Königstein. An Austrian army, under the command of Marshal Browne, advanced from Bohemia to the relief of Saxony, but was met by Frederick. A battle took place at Lowositz (1st October), which, though not decisive, ended in the retreat of the Austrians; and the famished Saxon army, after an ineffectual attempt to effect a retreat to Bohemia, laid down their arms. This ended the first campaign, and both sides did their utmost to prepare for renewing hostilities the following year. The empress strengthened her forces in Bohemia, and the 1757.
imperial diet conceded an army of 60,000 men to assist her. France engaged to send an army of 80,000 or 100,000 men into Germany, and Russia set in motion an army of 100,000 men against Prussia. In all, the allies were estimated to muster about 500,000 men, while Frederick could scarcely raise 200,000 of his own, his auxiliaries (English, Hanoverians, &c.) probably amounting to about 40,000 more. Frederick renewed the war by marching an army into Bohemia, where, on 6th May, he gained a victory over the Austrians, under Prince Charles of Lorraine, in the neighbourhood of Prague, and then laid siege to that city. General Daun, at the head of an Austrian army, advanced to the relief of the city, and the king set out to meet him. The encounter took place at Kolin (18th June), and the

Prussians, being much inferior in numbers, were beaten with great slaughter. Frederick was compelled at once to raise the siege and to evacuate Bohemia. In honour of this victory the empress instituted the military order of Maria Theresa. It had also the effect of inspiring the allies with fresh courage. The Russians invaded the kingdom of Prussia; the Swedes entered Pomerania; and two French armies crossed the Rhine in order to attack Hesse and Hanover and then march into Prussia. One of these armies, under the command of Prince Soubise, advanced towards Thuringia, in order to form a junction with the imperial forces under the prince of Hildburghausen, while Marshal d'Estrées, who commanded the larger French army, entered Hanover, and through the incapacity of his opponent, gained an easy victory over the Anglo-Germanic army, under the duke of Cumberland, near Hastenbeck, on the Weser (26th July). The duke afterwards completed his disgrace by agreeing to disband his troops and give up Hanover, Hesse, Brunswick, and the whole country between the Weser and the Rhine, to the French. The other French army effected a union with the imperial troops of Thuringia, and made preparations for driving the Prussians out of Saxony. Frederick, however, determined to meet them, and after a series of marches and countermarches the two armies came together near Rossbach. The Prussian army amounted to about 22,000 men, while that of the French and Austrians numbered nearly 60,000. Frederick's troops were encamped upon a height, and the allies, when they advanced to the attack, were suddenly met by such a tremendous fire that they were thrown into confusion and unable to recover themselves. In less than half an hour the day was decided (5th November 1757). The allies had 1200 killed and more than 7000 taken prisoners, while the loss of the Prussians scarcely exceeded 500 in killed and wounded. At this time the imperialists had entered Silesia and there gained several advantages over the Prussians, who were at length driven to the walls of Breslau. Here a battle was fought (22d November) in which the Austrians were victorious, and the city itself soon after surrendered to the conquerors. Frederick now made what haste he could to retrieve his fortunes in this quarter, and met the Austrian army, under Prince Charles of Lorraine, in a plain near the village of Leuthen. The Austrians numbered about 80,000 men, while the Prussians did not exceed 30,000, yet by the skilful disposal of his troops and the celerity of his movements Frederick again gained a complete victory (5th December). The field was covered with slain, and it is estimated that about 20,000 surrendered themselves prisoners. Breslau was speedily retaken, and the Austrians driven out of Silesia.

The English were very indignant at the treaty entered into by the duke of Cumberland, and another army was speedily raised and placed under the command of Duke
1758. Ferdinand of Brunswick, who commenced the campaign of 1758 by suddenly attacking the French in their winter quarters. In a few weeks he succeeded in driving them out of the country, pursued them across the Rhine, and attacked them furiously at Crefeld, where they were completely routed.

While Field-Marshal Daun, who had received the command of the Austrian army, was waiting the attack of Frederick in Bohemia, the latter, by forced marches, entered Moravia and laid siege to Olmütz. The town, however, defended itself with the greatest bravery, and the Prussians were compelled to raise the siege. By this time, Daun having blocked up Frederick's retreat into Silesia, the Prussian army was marched suddenly northward into Bohemia, and attacked the Russians who had invaded Brandenburg. After a desperate battle the latter were defeated with great slaughter at Zorndorf (26th August), and compelled to retreat into Poland. Frederick now entered Saxony, where his brother Prince Henry was hard pressed by the Austrians. Thereupon Daun retired to a strong position in Lusatia, and Frederick took up a position near him, little thinking that Daun would attack him. Early in the morning of the 14th of October, however, the Austrians suddenly fell upon him at the village of Hochkirchen, and in the confusion and darkness the slaughter was terrible. Frederick lost several of his best generals, including Prince Francis of Brunswick, Prince Maurice of Dessau, and Field-Marshal Keith, with about 9000 of his soldiers. His camp, baggage, and ammunition also fell into the hands of the Austrians. The victory, however, was productive of little material results; Frederick retreated into Silesia, while the Austrians, after ineffectual attempts on Leipsic, Torgau, and Dresden, retired to Bohemia for the winter. The Austrian army was again largely reinforced, and every preparation made for renewing hostilities with
vigour. The following year (1759) Duke Ferdinand found 1759.
himself hard pressed by two French armies under the Duke de Broglie and the Marshal de Contades. He sustained a defeat at Bergen (12th April), but afterwards gained a signal victory at Minden (1st August), and compelled the French to retreat. Daun, waiting the approach of the Russians, did not take the field till the beginning of May, when, on their advance towards the Oder, he moved into Lusatia. In June, Dohna, who was sent to check the advance of the Russians, was forced to retreat, and, on the 23d July, Wedel, who succeeded him in the command, was totally routed near Züllichau. The Russians then marched on to Frankfort-on-the Oder, where they were joined by 18,000 Austrians under Marshal Loudon. Frederick hastened with what troops he could collect to give battle to the combined army. The latter took up a strong position on the heights near Kunersdorf, and there they were attacked early on the 12th of August by the king. The Prussians numbered about 50,000, while the Russians and Austrians amounted to 90,000. The battle raged long and furiously, and the issue was long doubtful, but at length the Russians were giving way on all sides, and victory was about to declare for the Prussians, when unexpectedly the Austrians made a furious attack upon them, threw them into confusion, and in a short time drove them from the field. Frederick lost in this action 20,000 of his bravest troops, and the loss on the side of the allies was not less than 24,000 men killed and wounded. In the meantime the Austrians overran Saxony, took Torgau, Wittenberg, and Leipsic, and invested Dresden, which, after a spirited defence, surrendered when an army of relief was close at hand. But Frederick was speedily in the field again at the head of a new army, and, by dint of skilful manœuvring and cutting off supplies, he succeeded in harassing the two armies, and compelled the Russians again to retire into Poland. An army of 13,000 men, under General Fink, attacked the rear of the Austrian army near Maxen, but after a brief but sanguinary conflict they were defeated and taken prisoners. Daun took up his winter quarters in Saxony, notwithstanding every effort of Frederick to dispossess him.

The imperial troops had been very successful during the last campaign, and were in good condition to renew the fight, while the Prussians had sustained great losses, were dispirited, and could only muster about 80,000 fighting men, and these no longer veterans, but in great measure raw
recruits. In the campaign of 1760 Frederick was himself to 1760.
conduct the war in Saxony, Prince Henry was to protect the marches against the Russians, and General Fouquet was to defend Silesia against the Austrians under Loudon. On 23d June, 8000 Prussians, under Fouquet, were surrounded and attacked on all sides by 30,000 Austrians at Landshut,

and, after defending themselves long with great bravery, were obliged to yield. The king, after an ineffectual attack upon Dresden, marched into Silesia followed by the Austrians. At Liegnitz he found himself between three armies, under Generals Daun, Lacy, and Loudon, numbering about 90,000 men, while his own army amounted to only about 30,000. On the night preceding the 15th of August, Frederick took up a position on the neighbouring heights of Pfaffendorf. Scarcely had he done so when the Austrian army, under Loudon, made its appearance, it having also intended to occupy the same position, and then fall upon the Prussians. The Austrians were greatly astonished to find the enemy before them; nevertheless, they fought for three hours with great bravery, returning again and again to the attack, but were at length compelled to retreat with a loss of 4000 killed and 6000 wounded. Daun afterwards came up and made an attack upon the Prussians, but, learning what had happened to Loudon, he withdrew. Frederick now directed his march on Breslau; and meanwhile the Russians effected a junction with the Austrians, and marched on Berlin, which surrendered to them (3d October). A week later, hearing that the king was advancing against them, they left the city and retired into Saxony. Daun had likewise arrived in Saxony, and taken up a very strong position near Torgau. Here the Prussians attacked him with great fury on 3d November. The battle lasted till night without being decisive, and the carnage on both sides was fearful. The Prussians prepared to renew the attack next day, but the Austrians retreated during the night. They lost about 12,000 men killed and wounded, and 8000 prisoners. By this battle Frederick reconquered the greater part of Saxony, and accordingly he fixed his winter quarters there,
761. establishing his headquarters at Leipsic. In 1761 Frederick employed every stratagem to prevent the junction of the Russian army under Buturlin with the Austrian under Loudon. The two armies, however, at length came together in the environs of Strigau (12th August), the combined force amounting to 130,000 men, while the Prussians numbered only about 50,000. The leaders, however, could not agree to a common course of proceeding, and the two armies separated without effecting anything of consequence. The Austrians surprised and took Schweidnitz (1st October), and the Prussians, after a four months' siege, took possession of Colberg (13th December). In Saxony Prince Henry had to retreat before Daun; but the latter gained no great advantages, and Frederick settled in Breslau for the winter. It seemed as if Prussia must at last yield to her assailants, but this was as far as ever from the king's mind. To add to his difficulties, the subsidies from England were stopped by the earl of Bute after the death of George II. But by the death of the Czarina
762. Elizabeth (5th January 1762) he was freed from one of the most powerful of his enemies; and her successor, Peter III., not only recalled the army, but delivered up all the Prussian prisoners, and even entered into an alliance with the king. Sweden also retired from the contest, and entered into terms of peace. Frederick was therefore in a better condition to carry on the war vigorously against Austria, and the seventh campaign was marked by a series of disasters to that power. He attacked and overthrew Daun's right wing at Burkersdorf (21st July), gained a victory at Reichenbach (16th August), and took Schweidnitz after a very gallant defence (9th October). Prince Henry was also victorious at Freiberg (29th October). In the meantime Duke Ferdinand had been during the last three years successfully maintaining the war with the French. Fresh reinforcements and new generals were brought against him, but he could not be crushed; and, by the victories of Wilhelmsthal (24th June) and Luttern-burg (23d July), France was brought to agree to peace. Thus Austria and Prussia were left to carry on the war alone; and the former, though amply provided with troops, was without money to furnish the necessary supplies, while Frederick was ever ready to come to terms on having the possession of Silesia secured to him. Austria found herself obliged to yield this point, and peace was at length agreed to. The treaty was signed at the castle of Hubertsburg, in Saxony, 15th February 1763, and thus ended the Seven 1763.
Years' War,—a war disastrous to all concerned, and which is estimated to have cost in actual fighting men 853,000. It effected no territorial change in any of the countries, but through it Prussia rose to be one of the great powers of Europe. Austria, on her part, had carried on the conflict with remarkable vigour and determination; her soldiers had displayed great bravery, and some of her generals had shown a military genius not greatly inferior to that of Frederick himself.

Maria Theresa now zealously devoted herself to improving the condition of her people and country. She established schools, removed feudal hardships, improved the condition of the serfs, reformed ecclesiastical abuses, and fostered industry and commerce. The Emperor Francis died 18th August 1765, and was succeeded by his son, Joseph II., who the previous year had been elected king of the Romans. He also became joint-regent with his mother of the hereditary states. Maria established two collateral branches of her house in the persons of her two younger sons, the Archduke Leopold in Tuscany, and the Archduke Ferdinand, who married the heiress of Este, in Modena. By the first partition of Poland (1772) Austria acquired Galicia and Lodomeria, and in 1777 Buckowina was ceded by the Porte. On the death of the elector of Bavaria without issue, the Emperor Joseph laid claim to his dominions. To this Frederick was opposed, and again took the field against Austria. The dispute, however, was settled without war (1779), Austria being content with the cession by Bavaria of the frontier district called the quarter of the Inn, and one or two others. The empress died 29th November 1780, in the sixty-fourth year of her age and the forty-first of her reign. She was a woman of many and great virtues, with few weaknesses, and effected more for Austria than any of her predecessors. Mr Carlyle says that she was "most brave, high and pious minded; beautiful, too, and radiant with good nature, though of a temper that will easily catch fire; there is, perhaps, no nobler woman then living." At her death the monarchy comprised 234,500 square miles, with a population estimated at 24,000,000, and a public debt of 160,000,000 florins, or £16,000,000.

The Emperor Joseph II., whose zeal for reform had in great measure been kept in check during the lifetime of his mother, now felt himself at liberty to give it full scope. He attempted a number of changes, of which several were praiseworthy in their objects, but abrupt and premature in their operation, so that in the end they were productive of evil consequences. He sought to establish a system of central government and uniformity of legislation throughout his dominions; enjoined the exclusive use of the German language in all schools, courts of justice, &c.; granted free and unreserved toleration to all sects of Christians; abolished numerous convents and monasteries; dismantled various fortresses; and did away with primogeniture and feudal vassalage. Had his people been ripe for these changes he would probably have been hailed as a reformer of abuses; but the Austrians were attached to their old usages, and were little inclined for change, while the arbitrary manner in which the improvements were introduced could not fail to provoke discontent. General uneasiness, therefore, began to prevail, which in the Netherlands

broke out into open revolt in 1789. This, together with an unsuccessful war in which he had engaged with Russia against Turkey, is understood to have preyed upon his over-sensitive mind, and caused his death on 20th February 1790. He was, says Mr Carlyle, "a man of very high qualities, and much too conscious of them; a man of ambition without bounds; one of those fatal men—fatal to themselves first of all—who mistake half genius for whole; and rush on the second step without having made the first."

He was succeeded by his brother Leopold, grand duke of Tuscany, who by his moderation and firmness was successful in restoring peace to the country, and in quelling the insurrection in the Netherlands. He also made peace with the Porte. The misfortunes of his sister Maria Antoinette and her husband, Louis XVI. of France, led him to enter into an alliance with Prussia against the
1792. Revolutionists, but he died before the war broke out (1st March 1792). He was succeeded by his son, Francis II., who had hardly ascended the throne when he found

War with France.

himself involved in a war with France. Hostilities commenced on 28th April with an attempted invasion of Flanders by the French, but their undisciplined troops were speedily routed and put to flight. A combined army of 50,000 Prussians, under the command of the duke of Brunswick, and 15,000 Austrians under General Clairfait, besides about 20,000 French, soon after crossed the French frontier, took Longwy and Verdun, and marched on Paris. In the meantime Dumouriez was actively engaged in collecting an army, and soon found himself in a condition to meet them. A series of engagements took place without any decided result, beyond checking the advance of the allied troops, who were now also suffering very severely from sickness and famine. It was therefore deemed prudent to retire, and Verdun and Longwy were soon after retaken. Dumouriez next invaded the Netherlands with an army of 100,000 men, to oppose which the Austrian army only amounted to 40,000. A battle took place at Jemappes on the 6th of November, in which the Austrians fought with heroic bravery, and the contest was long doubtful, but the superior numbers of the French carried the day. The loss on both sides was very great; and soon after the whole of the Austrian Netherlands, with the exception of Luxemburg, was in the hands of the French.
1793. The commencement of the campaign of 1793 was distinguished by a series of brilliant victories gained by the allies in the Netherlands. Dumouriez was defeated at Aldenhoven, and again in a great battle at Neerwinden (18th March). Soon after, afraid of falling into the hands of the Jacobins in Paris, he passed over to the allies. His successor, General Dampierre, was defeated and slain on the plains of Famars, and the allies became masters of Valenciennes and Condé. Towards the end of the campaign, however, the republican troops were successful in a
1794. number of engagements. At the commencement of the year 1794, the Austrians, Dutch, English, and Hanoverians united their forces in the Netherlands under the command of the prince of Coburg, and the Emperor Francis himself joined the camp, in order by his presence to encourage the troops. In April the allies were successful at Cateau and at Landrecies, and took that town; but their good fortune then forsook them. Clairfait was attacked singly at Kortryk by Pichegru, and forced to yield to superior numbers; and the allies under the prince of Coburg were attacked by him at Tournay (22d May), when an extremely long and bloody, but undecisive, battle was fought. The Austrian troops were now greatly dispirited; and, on the 26th June they were defeated by General Jourdan at Fleurus. This was followed by other disasters, so that all Flanders was soon in the hands of the French. Pichegru, pursuing his victorious career, next invaded Holland, which, before the end of the year, was transformed into a republic. In the begin- 1795.
ning of 1795 Prussia abandoned the cause of the allies, and concluded a treaty of peace with the French republic at Basle (5th April), and was joined therein by Hanover and Hesse Cassel, so that Austria and England were left alone to prosecute the war. For some months a cessation of hostilities took place between the contending parties; but on the 6th of September the French army under Jourdan suddenly crossed the Rhine near Düsseldorf, invested that town, and drove the Austrians before it over the Maine. Clairfait, however, reassembled his troops behind the latter river, and attacked the French at Höchst, near Frankfort, and completely defeated them (11th October), so that they were obliged to recross the Rhine. In the meantime Pichegru had crossed the river with another army, near Mannheim, and took possession of that town. Wurmser, who was sent for its relief, arrived too late for that purpose, but attacked the French army near it, put them to flight, and compelled them to recross the Rhine, leaving a garrison of 8000 men to defend the town, which, after a vigorous siege, surrendered to the Austrians. The French, undismayed by these failures, were only stimulated to greater efforts; and the following 1796.
year they sent out three armies against Austria, one under Jourdan towards the Lower Rhine, another under Moreau towards the Upper Rhine, and a third into Italy. In the end of May the French army under Jourdan crossed the Lower Rhine, and gained some successes, but was afterwards attacked by the Archduke Charles (16th June), and forced to recross the river. Moreau soon after effected his passage over the Upper Rhine at Strasburg, defeated the Austrians in several partial engagements, and reduced the circle of Swabia to subjection. Jourdan again pushed forward his troops, and took Frankfort by bombardment, but was defeated with great loss by the archduke at Amberg (24th August), and again at Wurzburg (3d September). Moreau had in the meantime continued his advance into Bavaria, but was ultimately obliged to effect a retreat, which he carried out with great skill, suffering comparatively little loss, and recrossing the Rhine on 20th October. But a different fate was attending the army in Italy, under the command of a young officer, who afterwards became world-famous for his generalship, namely, Bonaparte. By the promptitude of his movements, and the suddenness of his attacks, he completely overcame and separated the army of the Sardinians from that of the Austrians, and forced the Sardinian king to sign a treaty of peace. He then turned his arms against the Austrians, defeated them in several engagements, and made himself master of the whole of Lombardy, except Mantua. Wurmser was now summoned from Germany with an army of 30,000 men, which raised the Austrian force to about 60,000; while opposed to them were about 55,000 French. Instead, however, of advancing in one body, the Austrians were divided into two columns, which advanced by different routes, a mistake of which Bonaparte did not fail to take advantage. One division of 20,000 men was attacked and compelled to retreat towards the mountains, while Wurmser with the other division entered Mantua. Leaving that city he sustained a double defeat at Lonato and Castiglione (3d August); and, being again severely beaten at Medola (5th August), he was forced to seek shelter in the mountains of Tyrol. Having received reinforcements, however, he again advanced in divided columns, one of which was defeated at Roveredo, the other, under himself, near Bassano. He took the road to Mantua with the remains of his army, and reached that town after a brilliant victory over a body of French troops that had been sent to intercept him. Meanwhile the Austrians collected another army of 40,000 men under Alvinzi, who, after a series of successes, gained a decided victory over Bonaparte at

Caldiero (11th November). Four days later the Austrians were again attacked by the French near the village of Arcola, and after three days' desperate fighting on both sides the Austrians at length retreated. Alvinzi received reinforcements, and again set out to attack the French, but suffered a severe defeat at Rivoli on 14th January 1797. A fortnight later Mantua capitulated, and the French became undisputed masters of the country. Speaking of the perseverance and patriotic spirit of the Austrians in this struggle in Italy, Sir A. Alison says, "It is impossible to contemplate without admiration the vast armies which they successively sent into the field, and the unconquerable courage with which these returned to a contest where so many thousands of their countrymen had perished before them. Had they been guided by greater or opposed by less ability they unquestionably would have been successful, and even against the soldiers of the army of Italy and the genius of Napoleon, the scales of fortune repeatedly hung equal."—(*History of Europe.*) The Archduke Charles was now recalled from the Rhine to oppose Bonaparte. The latter set out on his journey northward on the 10th of March, with the view of crossing the Alps and so reaching Vienna. The Austrians attempted to oppose his progress at the river Tagliamento, but without success; and a desperate struggle took place for the possession of the Col de Tarvis, which ended in favour of Napoleon, so that in twenty days after the campaign opened the army of the archduke was driven over the Julian Alps, and the victorious French army of 45,000 strong was on the northern declivity of the Alps, within 60 leagues of Vienna. Napoleon, still pressing on, took possession of Klagenfurt, and advanced as far as Judenburg on the River Mur; but finding his position very insecure, and dangers thickening upon him, he despaired of carrying out his intention of dictating peace under the walls of Vienna. He therefore offered terms of accommodation to the Austrians, which they deemed it prudent to accept. Preliminaries were agreed to at Leoben (18th April), and a formal treaty of peace was signed at Campo Formio, 17th October 1797. By this treaty Austria ceded to France Flanders and her Italian possessions, and received in return Venice and its dependent provinces. It, however, contained certain secret articles, by one of which Austria consented to surrender the whole of the left bank of the Rhine to France; and a convention was appointed to meet at Rastadt to provide equivalents on the right bank for the princes dispossessed on the left, and otherwise to settle the affairs of the empire. The terms were not particularly hard as regards Austria. The ceded territories contained about 3,500,000 souls, and those acquired about 3,400,000. But the taking away of the independence of Venice, which had been maintained for 1400 years, was an act of rapacity which excited the indignation of Europe, and Austria's share in it must ever remain a stain on her annals.

This peace was not of long duration. As the business of a convention which met at Rastadt advanced, and the bearing of the secret articles became known, a great sensation was created in Germany. The high-handed manner in which the French conducted their negotiations, and the insolence and contempt with which they treated the empire, led to the recall of the Austrian ambassador from the convention in the beginning of 1799, and on the 13th of March France again declared war against Austria. In the meantime the latter power had entered into an alliance with England and Russia against the former. In Germany the Archduke Charles defeated Jourdan at Stockach (26th March), and in several other encounters, and drove him out of the country; and he afterwards reconquered the whole of the western portion of Switzerland to beyond Zurich from Massena. In Italy Scherer was defeated by the Austrian general Kray at Verona and at Magnano, and then resigned the command into the hands of Moreau. The Russian army, under Suwaroff, now formed a junction with the Austrian, and the French were again beaten near Cassano (27th April). This was followed by other successes, so that in less than three months the French standards were driven back to the summit of the Alps, and the whole plain of Lombardy, with the exception of a few of its strongest fortresses, was recovered. After this the Russian general marched against Macdonald, who was advancing with a French army from Naples. A desperate conflict took place on the banks of the Trebbia, which was maintained with consummate bravery and skill for three days (17-19 June), until victory declared for the Russians. Out of 36,000 men in the field the French lost above 12,000 in killed and wounded, and the allies nearly as many. One place after another now fell into the hands of the allies; but mutual jealousies and divisions breaking out among them, the Russian and Austrian forces were eventually separated. This led to the most disastrous results. The Russians were to prosecute the war in Switzerland, while the Austrians remained to carry it on in Italy. In the meantime another French army had been collected under General Joubert; and, on the 15th of August he was attacked by the allies at Novi. The battle was long and obstinate, but at length the allies were victorious. The French lost their general, who fell mortally wounded, besides about 1500 killed, 5500 wounded, and 3000 prisoners. The loss of the allies was 1800 killed, 5200 wounded, and 1200 prisoners. The Russian general now directed his march towards the Alps, forced the St. Gotthard, and descended into the valley of the Urseren, driving the French before him with great slaughter. With great difficulty and loss he effected a passage through the horrible defile of the Shächenthal, between Altdorf and Mutten; but, at the latter place, instead of meeting the allied troops, as he had expected, he found himself in the midst of the enemy. Before this time Massena had so beset the Russian general Korsakoff at Zürich, that he was compelled to fight, and with difficulty made his escape with the remains of his army, while the Austrian forces under Hotze had also been beaten by Soult. Nothing remained for Suwaroff but retreat, a course which he adopted with extreme reluctance, making his way with incredible resolution and perseverance over the rugged Alps into Glarus and the Grisons, and at length reaching the valley of the Rhine (10th October). Disagreements having taken place between the Austrian and Russian generals regarding their future proceedings, the latter withdrew to winter quarters in Bavaria; and soon after this the capricious czar of Russia, Paul, withdrew from the alliance and recalled his troops.

Bonaparte, who had now returned from his Egyptian 1800.
campaign, made proposals for peace, which were rejected, and both sides prepared to renew the contest in 1800. A numerous and well-appointed French army was collected at Dijon, at the head of which the first consul suddenly put himself, and set out for Italy across the Great St. Bernard. The passage was effected with great skill and determination in spite of every obstacle, and he arrived in Lombardy before Melas, the Austrian general there, had been informed of the expedition. On the 14th of June a great battle took place near the village of Marengo, the most obstinate and sanguinary that had up to this time been fought. The Austrian army numbered 21,000 foot and 7000 horse, while opposed to them was an army of 22,000 men. The battle was maintained with great spirit and obstinacy on both sides; but at length, after repeated charges, the French were compelled to give way, and the retreat became general. At this moment, however, a fresh body of

French troops under Desaix arriving on the field the contest was renewed, and after a final struggle the Austrians were compelled to yield. They lost about 7000 men in killed and wounded, and 3000 prisoners; while the French lost about the same number in killed and wounded, and 1000 prisoners, taken in the early part of the day. Their retreat being cut off, the Austrians capitulated to the conqueror, who thus again acquired possession of the whole of Italy. In the meantime Moreau had invaded Germany and defeated Kray in several engagements, particularly at Stockach and Möskirch, and again at Biberach and Hochstädt; he also took Munich, and laid Bavaria and Swabia under contribution. An armistice was now agreed to (Parsdorf, 15th July), and overtures were made for peace, but without success. Hostilities were resumed in the end of November, and at first the Austrians gained some advantages, but on the 3d of December they sustained a crushing defeat at Hohenlinden. The fight was long and obstinate; the French lost on that and the preceding days 9000 men, while the loss of the Austrians was nearly twice as great. The moral effects of the defeat were most disastrous. Moreau now advanced by hasty marches, crossed the Inn, took Salzburg, and pressed on towards Vienna, but an armistice was agreed to on 25th December. In Italy the Austrian forces sustained a severe defeat at the passage of the Mincio (26th December).
1801. Suffering under these disasters Austria was glad to agree to terms, which were concluded at Luneville, 9th February 1801.

By this treaty the whole of the left bank of the Rhine was again ceded to France, and the Adige was declared to be the boundary of Austria in Italy; the grand duke of Tuscany, on the promise of an indemnity in Germany, renounced his dukedom in favour of the infant duke of Parma, created king of Etruria; the duke of Modena received the margraviate of Breisgau in exchange for his territory; and the independence of the Batavian, Helvetic, Cisalpine, and Ligurian republics was recognised and guaranteed. A convention was to be again summoned for the regulation and adjustment of the rights of all concerned. In order to provide indemnities for the despoiled princes, a large proportion of the ecclesiastical sovereignties of the empire was *secularised*, or, in other words, confiscated; and all the free imperial cities were deprived of their privileges with the exception of six. To the share of Prussia fell the bishoprics of Hildesheim and Paderborn, the city of Munster, and other cities and abbacies, to the amount of more than four times what she had lost on the left bank of the Rhine. Thus was she rewarded for her discreditable neutrality and impolitic desertion of the European alliance, though she subsequently suffered for this at Jena and by the treaty of Tilsit. The grand duke of Tuscany received the archbishopric of Salzburg, the bishopric of Eichstadt, and part of that of Passau, in exchange for his hereditary possessions. Austria received the Tyrolese archbishoprics of Trent and Brixen. She had also received, in 1795, Western Galicia as her share in the third division of Poland, so that now her territory comprised over 254,000 square miles, her public debt amounting to 1,220,000,000 florins, or £122,000,000.

Austria now enjoyed a short period of peace, and employed it in silently repairing the breaches in her army and finances which had been produced by the late wars. After Napoleon had assumed the title of emperor of the French, the Emperor Francis took for himself and his successors that of emperor of Austria (11th August 1804). On 11th
1805. April 1805, an alliance was formed between England and Russia for resisting the encroachments of France, and some months later Austria and Sweden likewise joined it. Prussia held aloof, in the hope of receiving Hanover as a reward for her neutrality; while Baden, Würtemberg, and Bavaria sided with France. Deceived by the efforts that Napoleon was ostensibly making for the invasion of England, the Austrians (9th September) crossed the Inn, invaded Bavaria, and took up a position in the Black Forest. Meanwhile the French troops were in full march from the shores of the Channel to the banks of the Rhine; and the force in Hanover, under Bernadotte, was ordered to cross the Prussian territory without asking permission, and form a junction with the Bavarians in the rear of the Austrians, while other corps were at the same time directed by circuitous routes upon their flanks. The Austrian general, Mack, on the first intelligence of the approach of the French, had concentrated his forces at Ulm, Memmingen, and Stockach, contemplating an attack only in front. Great was his consternation, therefore, when he found that there was also an army on his rear. After several partial engagements, in which the Austrians were defeated, the Archduke Ferdinand, at the head of a body of cavalry, succeeded in making his way through the enemy, and in reaching Bohemia; while Mack, with the rest of the army, shut himself up in Ulm, which, with 30,000 men, he was forced to surrender (20th October). After this, Napoleon with his usual rapidity, marched with the main body of his troops upon Vienna, and on the 5th of November established his headquarters at Linz, the capital of Upper Austria. The Russian and Austrian troops made various attempts to obstruct his farther progress (particularly at Dürrenstein, where a desperate engagement took place), but without success; and, on the 13th November, Vienna was in the hands of the conqueror, who made his headquarters at Schönbrunn. In the meantime the Archduke Charles was with the army in Italy, where, on 29th October, he was attacked with great fury on the heights of Caldiero, by the French under Massena. A terrible conflict ensued, and continued till night parted the combatants. It was renewed the following day, when at length victory declared for the Austrians. The archduke, however, was unable to avail himself of his success, for, hearing of the unfortunate state of matters in Germany, he set out with his army for the defence of the capital, and conducted it with great skill over the mountains, so that it suffered no serious loss. Marshal Ney, who had been sent with a body of troops into Tyrol, succeeded in taking the mountain barrier of Scharnitz by storm, and in making himself master of Innsbruck. Two bodies of Austrian troops had been so hard pressed that they were obliged to capitulate—one under General Jellachich at Feldkirch, and another under the Prince de Rohan at Castel-Franco in Italy.

After the loss of Vienna the allied forces collected themselves in Moravia, whither they were followed by Napoleon. At length the two armies came in sight of each other at Austerlitz, and both sides prepared for battle, which it was felt must be a most momentous one, and was to be witnessed by three emperors (those of France, Austria, and Russia). The allied forces numbered fully 80,000 men, of whom 15,000 were cavalry, while the French had 90,000 men in the field. The army of the allies was not well generaled, while on the side of the French were Soult, Bernadotte, Davoust, Murat, Lannes, Oudinot, Bessières, &c. The battle commenced on the morning of the 2d December, and continued till night. Both sides displayed the greatest skill and bravery; at one part of the field the allies would be victorious, at another the French; at one time victory would incline to the French, and again to the allies. At length, however, towards evening, the allies came to be beaten at all points, and the route soon became general. Numbers sought to save themselves by crossing the frozen lake of Satschan; but shots from the French batteries on the heights above broke the ice in all directions, and about

2000 men perished. The allies lost about 30,000 men, killed, wounded, or made prisoners, while the French lost about 12,000 in killed and wounded. This was the most glorious of all Napoleon's victories; but he was still in a very dangerous position. The Archduke Charles, with an army of 80,000 men, was now approaching Vienna; Hungary was rising *en masse* against him; Russian reserves were advancing; and Prussia was at length preparing to declare war, on account of the unauthorised passage of French troops through her territories. From these difficulties, however, he was freed by the desire of the Emperor Francis for peace. An armistice was agreed to, and finally a treaty of peace was drawn up and signed at Presburg (25th December 1805). By this treaty Austria ceded to Bavaria, now erected into a kingdom, the whole of the Tyrol, Vorarlberg, Lindau, Burgau, Passau, Eichstädt, Trent, and Brixen, besides several petty lordships; to Würtemberg, now also become a kingdom, the bordering Austrian dominions in Swabia; and to Baden the Breisgau, the Ortenau, and the town of Constance. She also yielded up her Venetian possessions, and agreed to pay a war contribution of £1,600,000. In exchange for all these sacrifices she merely received the small electorate of Salzburg, and the possessions of the Teutonic Order. In all, Austria lost about 28,000 square miles of territory, with a population of 2,700,000, and a revenue of 14,175,000 florins. It was evidently not the intention of Napoleon to overthrow the Austrian monarchy, but rather to throw its strength to the eastward, and to impose a barrier of subordinate kingdoms between it and France, so as to prevent its interference with his schemes of aggrandisement in Germany and Italy.

A blow was inflicted upon the constitution of the German empire by Napoleon, in the formation of the Confederation of the Rhine. Representatives of the different powers concerned assembled at Paris in the beginning of July 1806; and, on the 12th of that month, an Act was signed whereby the kings of Bavaria and Würtemberg, the elector of Baden, and thirteen other princes of Western Germany, separated themselves from the German empire, and formed a confederation under the protection of the emperor of the French. 16,000,000 men were thus, by a single stroke, transferred from the empire to a foreign alliance. Wisely yielding to what he could not prevent, the Emperor Francis, by solemn deed, renounced the title of emperor of the Romans, and declared himself the first of the emperors of Austria.

The peace of Presburg was quickly followed by the war between France and Prussia, in which the latter suffered terrible retribution for her selfish policy in leaving Austria to struggle unaided against the common foe of Europe. Great efforts were made to induce Austria to take part in this war, but she prudently remained neutral, contenting herself with making every effort to strengthen and improve her army, and increase her warlike resources. During the whole of 1806 and 1807 the efforts of the war department, under the guidance of the Archduke Charles, were incessant to restore the losses that had been sustained in the late war. The army was also remodelled upon the system adopted by Napoleon. The transfer of a large portion of the French army in Germany to the Peninsula on the breaking out of war there, emboldened the Austrian Government to issue a decree (9th June, 1808), instituting a landwehr or militia to be raised by conscription, which soon amounted to 300,000 men, in addition to a regular standing army of 350,000. On hearing of this, Napoleon addressed strong remonstrances to the court at Vienna, which made loud professions of pacific intentions, but did not cease its warlike preparations. In the spring of 1809 the armies on both sides took the field, and, on 8th April, Austrian troops crossed the frontiers at once in Bohemia, on the Inn, in the Tyrol, and in Italy. In the meantime France was bringing together her forces from all quarters towards the valley of the Danube, where at length she had an army, including the troops of the German Confederation, of about 200,000 men, and Berthier was despatched to take the command till the arrival of the emperor. The Archduke Charles had crossed the Inn with upwards of 120,000 men, and on the 16th they had advanced as far as the Isar, which they crossed. Berthier, instead of concentrating his troops, was separating them, so that they were in the utmost danger, when the arrival of Napoleon at once changed the aspect of affairs. On the 19th an action took place at Thaun, between a body of about 20,000 French and a like number of Austrians, without any decisive result; and the following day the main body of the Austrians, over 50,000 strong, was suddenly attacked and defeated after a feeble resistance at Abensberg, by a French army of 65,000 men. The same day the Austrians attacked and took Ratisbon, and secured the bridge over the Danube there. Both sides now prepared for a general engagement, which took place at Eckmühl on the 22d of April. The battle was bravely contested; but at length the French were victorious, the loss to the Austrians being 5000 killed and wounded, and 7000 prisoners. The archduke retired during the night to recruit his army in Bohemia, and Ratisbon was taken by storm. In other parts, particularly in Italy, success was attending the Austrian arms.

Napoleon now lost no time in again marching on to Vienna, and no great attempt was made to impede his progress except at Ebersberg, where Hiller with about 30,000 Austrians took his stand to defend the wooden bridge over the Traun. He was gallantly attacked by a body of French troops under Massena, and a fearful struggle took place; but at length the French prevailed, and Hiller withdrew his troops. Each side lost about 6000 men on this occasion. On the 10th of May the French eagles appeared before the walls of Vienna, and, after an ineffectual attempt at defence, the city surrendered on the 13th. The Archduke Charles was hastening to the relief of the town, but arrived too late. The two armies therefore prepared for battle, the one on the north bank of the Danube, the other on the south. On the night of the 19th the French prepared to cross the river at the island of Lobau, and by daybreak on the 21st they had 40,000 men landed on the northern side. The Austrians now resolved upon an attack, and by two o'clock, when the fight began, the French force amounted to about 50,000 men, while the Austrians had 80,000 to oppose them. The scene of action was near the villages of Aspern and Essling, and the struggle was maintained with the most desperate courage on both sides till night parted the combatants. The Austrians had everywhere the advantage, but both sides prepared to renew the contest the next day. During the night, and early in the morning, French troops were still passing over, so that, notwithstanding his losses, Napoleon had fully 70,000 men to renew the fight. It commenced early in the morning, and continued the greater part of the day; but at length the French were beaten on all sides, and compelled to retreat to the island of Lobau. In these two days they lost upwards of 30,000 men, and the Austrians not less than 20,000. The victory produced a great impression on the mind of Europe, and dissipated in a great degree the charm of Napoleon's invincibility.

He, however, made every preparation for renewing the contest. He summoned troops from different parts, and fortified his position on the island of Lobau, connecting it also by several bridges with the south bank of the river. On the evening of the 4th of July he assembled his troops on the island, amounting to 150,000 infantry and 30,000

cavalry, with 750 pieces of cannon. During the night several bridges, which had been secretly prepared, were thrown over to the northern bank at a point where they were not looked for, and by six o'clock the following morning the whole body had passed over. In the afternoon the French made a vehement attack upon the Austrians, but were repulsed with great slaughter. Early on the morning of the 6th the Austrians began the attack. Their numbers were then about 115,000 infantry and 25,000 cavalry; but they were in hourly expectation of the arrival of an additional body of 30,000 under the Archduke John, which was known to be not far off. The battle was contested with the utmost determination and bravery on both sides. The Austrian right wing succeeded in overthrowing and putting to flight the left wing of the enemy. On the other wing the contest was long and doubtful; but two divisions of troops having at length succeeded in turning the extreme flank of the Austrians, the latter, after a gallant defence, were compelled to abandon their position. In these circumstances, Napoleon collected all his disposable forces and brought them to bear upon the centre of the Austrians, which was their weak point, the archduke having thrown his strength chiefly into the two wings. After repeated charges, which were repulsed with great bravery, the French succeeded in forcing their line, and the archduke, despairing of maintaining his position, ordered a retreat, which was effected in good order and with little loss. The French were so exhausted that they displayed little vigour in the pursuit, and neither guns nor prisoners were taken. The Archduke John came up in the afternoon, but too late to be of any service. Had he made his appearance sooner there can be no doubt that the result would have been different. As it was, the Austrians succeeded in making a most gallant stand against a greater number of the best troops of France, led by Napoleon and some of his greatest generals. This battle of Wagram was one of the greatest and most obstinately contested fights in the whole war, and is perhaps the most glorious in the annals of Austria. The loss on both sides was immense, amounting to about 25,000 on each, including killed and wounded. The Archduke Charles retreated towards Bohemia without any serious molestation from the enemy. A battle was fought at Znaim (11th July) between the Austrians and a French army under Massena which was following them, but before it was decided news of an armistice arrived. This was followed by the peace of Vienna (14th October). "The campaign of Aspern and Wagram," says Sir A. Alison, "is the most glorious in the Austrian annals,—one of the most memorable examples of patriotic resistance recorded in the history of the world. . . . Other empires have almost invariably succumbed upon the capture of the capital. . . . Austria is the only state recorded in history which (without the aid of a rigorous climate like Moscow) fought two desperate battles in defence of its independence after its capital had fallen." —(*History of Europe.*) By the peace of Vienna Austria was compelled to cede Salzburg, Berchtesgaden, the Innviertel, and the Hausruckviertel, to Bavaria; portions of Galicia to Russia and the grand duke of Warsaw; and Carniola, Trieste, the greater part of Croatia, Istria, the circle of Villach, &c., to Italy. In all she lost about 42,000 square miles of territory and 3,500,000 inhabitants, together with more than 11,000,000 florins of revenue. The emperor also agreed to reduce his army to not more than 150,000 men; and a war contribution of £3,400,000 was imposed on the provinces occupied by the French troops. Before leaving the Austrian capital Napoleon caused the fortifications to be blown up.

Soon after this Napoleon obtained a divorce from his wife Josephine, and offered his hand to Maria Louisa, daughter of the emperor of Austria, and was accepted. The marriage was celebrated with great pomp at Vienna on the 11th March 1810. In 1812 Austria was obliged to enter into an alliance with France against Russia, and to furnish an auxiliary force of 30,000 men for the invasion of the latter country. The disastrous result of that expedition to the invaders showed Germany that the fortunate moment had now arrived for regaining her independence. Prussia was the first to form an alliance with Russia, and 1813. declared war against France (17th March 1813). Great efforts were made to induce Austria to join this alliance, but without success. She directed her attention to raising her military strength, and making other preparations to enable her to take an important part in the coming struggle, on the one side or the other. After the defeat of the allies at Lützen and Bautzen, and the conclusion of an armistice at Pleswitz, Austria came forward as a mediator, with the view of effecting a peace between the parties, and not without the view, also, of gaining some material advantage for herself. In fact, she now held in her hand the balance between the contending parties. Her army of 150,000 or 200,000, which she had collected in Bohemia, would bring victory to whatever side she joined. Metternich, who at that period had the direction of the cabinet of Vienna, was too clear-headed not to perceive the advantages of the position, and he determined to avail himself of them, in order if possible to restore to Austria her lost possessions. He had openly avowed, that if Napoleon would accede to the terms which he proposed Austria would throw her whole 200,000 men into the scale in his favour. At first it seemed doubtful to which side she would attach herself; but it would appear that the allies had reason to believe that she was favourable to them, and that Napoleon had also reason for suspecting the strength of her attachment to him. It is evident that she would have more to expect from the allies than from Napoleon, but at the same time it was doubtful how far she would be influenced by the existing matrimonial alliance. While things were in this doubtful state news arrived of the battle of Vitoria, by which the deathblow was given to the power of France in the Peninsula, and after this there was little hope of peace on either side. Austria, whatever her previous intentions, doubtless now felt that there was little to be gained from attaching herself to a sinking empire and a falling cause, and she agreed, in the event of Napoleon not accepting the terms proposed, to join the allies. They could have had little hope that the terms would be accepted; they included the cession to Austria of all the Illyrian provinces, with Trieste, the reinstatement of Prussia in her ancient possessions, with a frontier on the Elbe, and the dissolution of the grand duchy of Warsaw, to be divided between Russia, Austria, and Prussia. These terms not being acceded to, both parties prepared for war. Austria agreed to furnish 200,000 to the allied forces, stipulating in return that she should be restored to the condition in which she was in 1803, or, at any rate, at the peace of Presburg.

By gigantic efforts Napoleon was able to raise his army to 400,000 men, of whom nearly 350,000 were effective, and he resolved to make Dresden the pivot on which all his operations should turn. To oppose him the allies mustered about 400,000 men, so that the two forces were pretty nearly equal. Of the latter, a grand army of 220,000 men, chiefly Austrians, under Prince Schwarzenberg, was stationed in Bohemia; Blücher, with 95,000 men, was to protect Silesia; while Bernadotte, the crown prince of Sweden, who had joined the allies with 28,000 troops, was to protect Berlin and Brandenburg with an army of 90,000. Napoleon resolved to march with the main body of his troops into Silesia against Blücher, having despatched an army of 80,000 men under Oudinot against Berlin, and

sending a force of 30,000 to keep the passes from Bohemia to Dresden. Blücher judiciously retreated before the French troops, and while Napoleon was following him, the allied army in Bohemia came down upon Dresden. In place, however, of at once beginning the attack, it was delayed till Bonaparte, who had been informed of their movements, had time to arrive. The attack was commenced on 28th August, and kept up with great fury during the day; but in the evening a series of sallies were made from the town, which took the besiegers completely by surprise, and compelled them to withdraw. Napoleon had now received sufficient reinforcements to enable him to give battle, which he did the next day. He was then able to muster 130,000 men, while the allies numbered about 160,000. The fight was maintained for some time with great bravery on both sides, but at length a body of French troops under Murat succeeded in turning the flank of the allied left wing, and then attacking them suddenly on flank and rear; they were thus thrown into confusion, and the great body of them killed or made prisoners. The allies lost on this occasion about 26,000 men, of whom about 13,000 were prisoners. A French force under Vandamme had been sent to cut off the retreat of the allies, but this was engaged near Culm (29th August) by a body of Russians under Ostermann, and a desperate struggle took place, which was renewed the next day, and only ended by the appearance in the rear of the French of a large body of Prussians, when the leader and most of his troops were made prisoners. The French lost in the two days 18,000 men, of whom 7000 were prisoners.

Napoleon, on quitting Silesia, had left Macdonald with an army of 80,000 men to oppose Blücher. The latter suddenly attacked them with great fury on the Katzbach (26th August), and defeated them with great slaughter. The fight was several times renewed during the three following days when the allies were in pursuit, and in all the French lost about 7000 men in killed and wounded, and 18,000 prisoners. Nor was the French army under Oudinot more successful, for it sustained a severe defeat at Gross Beeren (23d August), and in that and subsequent engagements lost about 4000 in killed and wounded, and an equal number of prisoners. Napoleon was strongly affected by these reverses, the more so that they were quite unexpected. He gave the command of the army in the north to Ney, and set out himself against Blücher. Ney engaged the allied army at Dennewitz, and a desperate battle was fought (6th September), in which the French were at length beaten and put to flight with a loss of 13,000 men, of whom one-half were prisoners. The army in Bohemia now again resumed the offensive, and was preparing to fall upon Dresden, when Napoleon suddenly returned and drove them back. He again marched against Blücher, but returned to Dresden without effecting anything. He then resolved to enter Prussia and take Berlin, but was obliged to give up this project on learning that Bavaria had joined the allies (8th October). Now fearing that his retreat might be cut off, he directed his march towards the Rhine, and reached Leipsic on the 15th of October. Here the combined allied armies under Schwarzenberg, Blücher, and Bernadotte assembled, and on the 16th an indecisive battle was fought, which to the French was equivalent to a defeat, and the same evening Napoleon made proposals for peace, but no answer was returned. The battle was renewed on the 18th. The French army numbered about 175,000 men, while the allied forces amounted to about 290,000. The French strength was also weakened by two Saxon brigades of foot and one of cavalry passing over to the enemy during the engagement. Notwithstanding these disadvantages the French fought with great bravery and determination, but were at length beaten on every side. Next day they were in full retreat, and Leipsic was taken by the allies after a gallant defence. The total loss of the French during these four days exceeded 60,000 men. The emperor reached Erfurt on the 23d October, and there collected the scattered remains of his army. The Bavarians, under Wrede, attempted to intercept his retreat at Hanau, but though aided by some of the allied troops, they were defeated with great slaughter (30th October). The Rhine was crossed on 1st November, and on the 9th Napoleon arrived in Paris. Thus Germany regained its independence, and the Confederation of the Rhine was dissolved. Austria, as we have seen, had a principal share in bringing this about; but the Emperor Francis was opposed to the adoption of extreme measures against Napoleon, being desirous that the sceptre of France should continue in the hands of his daughter and her descendants. Other views, however, prevailed. The war was 1814.
carried into the enemy's country, and at length, not without a good deal of fighting, the allies entered Paris on 31st March 1814. On 11th April Napoleon resigned the imperial crown.

In the end of September following a congress was assembled at Vienna to adjust the claims and the mutual relations of the several states. This, however, was found to be a matter of no small difficulty. Russia demanded the whole of Poland, and Prussia laid claim to Saxony. Austria, France, and England were opposed to these claims, and determined to resist them, so that at one time it appeared as if war was again to break out; but more peaceful views began to prevail, and when the news arrived that Napoleon 1815.
had secretly quitted Elba, all minor differences were forgotten in the presence of this pressing danger. They at once declared him an enemy and a disturber of the peace of the world, and prepared to bring against him an army of upwards of half a million of men. But before these had all been collected, Wellington and Blücher had brought the military career of Bonaparte to a close on the field of Waterloo. In the new partition of Europe, which was fixed by the Congress of Vienna (1815), Austria received Lombardy and Venice, the Illyrian provinces, Dalmatia, the Tyrol, Vorarlberg, Salzburg, the Innviertel, and Hausruckviertel, together with the part of Galicia formerly ceded by her, making in all about 3,200 square miles of territory.

The emperors of Austria and Russia and the king of Prussia also entered into a "Holy Alliance," by which they bound themselves to remain united in the bands of true and brotherly love, to mutually help and assist each other, to govern their people like fathers of families, and to maintain religion, peace, and justice in their dominions. This alliance, beautiful in theory, was made, in fact, the means of maintaining absolute power in the hands of the rulers, and of suppressing free institutions and almost every form of liberty among the people. This was particularly the case in Austria, under the direction of Metternich, who did everything in his power to carry out these principles. A strict censorship of the press was established, not only to overlook the home press, but also to superintend the introduction of foreign publications. A system of secret police was also organised to observe and report what was said and done by the people in private. Besides this, Austria was ever ready to aid in the suppression of revolutionary movements in other states. In the construction of the German Confederation she used her influence to suppress the popular voice in all matters of government; her armies were employed in quelling the popular insurrections in Naples and Piedmont in 1822; and by diplomacy she aided in the suppression of the popular movement in Spain in 1823. During the insurrection in Greece the influence of Austria was exerted against it; and when Greece was established as a kingdom (1827), under the protection of England,

France, and Russia, she kept aloof. When, however, Russia invaded Turkey in 1828, Austria joined with England in interfering to prevent the fall of Constantinople, and in bringing about peace.

The commotions that followed the French revolution of July 1830 in different parts of Europe considerably affected Austria. This manifested itself chiefly in Lombardy, where the presence of 30,000 troops was required to maintain the imperial authority. In Parma and Modena the people suddenly rose in insurrection and expelled their rulers, and Austrian troops were employed to restore them. An insurrection also broke out in the Papal States, and the Pope invoked the aid of Austria, whose troops entered Bologna and established themselves there (January 1832). Upon this the French sent a force to occupy Ancona, and at one time it seemed as if France and Austria were again to cross swords on Italian soil, but this danger was at length averted. In the minor states of Germany the cry for popular institutions was raised, and in many cases the rulers were obliged for a time to comply with them, but after the danger appeared to pass away, Austria, acting in concert with Prussia, succeeded in bringing back the old state of things in the confederation. The Poles, tired of Russian rule, and hoping to be supported by France, took up arms to regain their independence (1831). Although Austria professed a strict neutrality in the struggle, a Polish corps that was driven into her territories was disarmed and detained, while a body of Russian troops under the same circumstances was allowed to continue its operations against Poland. During the remainder of the reign of Francis I. no public event of importance occurred. He died on the 2d of March 1835, in the sixty-seventh year of his age and the forth-third of his reign. He was one of those well-meaning but weak-minded men, who unfortunately adopt the wrong means for effecting the good which they intend. He wished to make his people contented and happy, but he sought to do so by repressing all independence in thought or action, and keeping them in the most abject subjection. He earnestly strove for their advancement, but it was by strenuously endeavouring to keep things as they were, and opposing every form of change. The transition from an old to a new state of things was in his mind always associated with the utmost danger, and to be by all means avoided. He did much in the way of establishing elementary schools throughout the country, but said that he wished to have no learned men, only good loyal citizens. He was thoroughly conscientious and correct in his conduct, but at the same time narrow-minded, suspicious, and bigoted. He was most assiduous in his attention to the business of the state, but occupied himself chiefly with small matters and minor details, while more important concerns were entirely overlooked and neglected. His good qualities, however, commended him to the affections of his people, and this doubtless did much to repress among his subjects the insurrectionary spirit which subsequently manifested itself.

He was succeeded by his eldest son, Ferdinand I., an amiable but weak-minded prince, who left the government very much in the hands of his prime minister, Metternich. The various signs of discontent which had been manifested during the former reign soon became stronger and more marked. Baron Pillersdorf, the successor of Metternich, speaking of this period, says, "Circumstances permitted an uninterrupted enjoyment of peace, but the necessity for internal ameliorations became by so long a delay more urgent, the demand for them more sensible, whilst, owing to the procrastinations of the Government, faith and confidence were diminished. It is true that the prosperity of the provinces generally did not decline; on the contrary, many branches of commerce manifested an increase in their development; but in spite of this the situation of the whole empire inspired in different respects serious apprehensions, arising from the disordered state of the economy of finance, the yearly augmentation of the public debt, the inefficiency of the measures adopted, and still more from the oppressed disposition of mind of the clear-sighted and intelligent classes of the population."—(*The Political Movement in Austria during* 1848-49.) The people saw growing up in the nations around them freer institutions and more liberal modes of government, and they could not help contrasting those with their own system. Austria, too, was made up of a number of different nationalities, and the Government attempted to strengthen its position by working upon their national prejudices and antipathies, setting race against race, and creed against creed. In particular, the German element was favoured at the expense of the other nationalities; and the Germanising measures of the Government excited great discontent among the other races. It has been remarked that the aversion of Austria to the development of the Slavonic element in her population was greatly owing to jealousy of Russia, which power she regarded as desirous of attaching all the Slavonic races to itself. Hence Austria has always been opposed to the encroachments of Russia in Turkey, and in favour of maintaining the integrity of the latter, so that, when war broke out in 1839 between the Sublime Porte and the Pasha of Egypt, she readily joined England in support of the former.

The Court of Vienna was first frightened from its sense of security by an insurrection in Galicia in 1846. This having been suppressed, Austria, in conjunction with the other two powers which had dismembered Poland, determined to lay hold on Cracow, and thus extinguish the last remnant of Polish independence. This step being contrary to the treaty of Vienna, was strongly remonstrated against both by England and France; but these remonstrances were unheeded, and the republic was incorporated in the Austrian empire. The French revolution of 1848, which convulsed almost the whole of continental Europe, caused the Austrian empire to totter to its foundations. Scarcely had the news of the fall of Louis Philippe reached Vienna when the whole city was in a state of open rebellion (13th March). The populace, headed by the students, and forcing the magistracy along with them, made their way into the imperial palace, and loudly demanded from the emperor the dismissal of his old counsellors, and the immediate grant of a new constitution. Alarmed at these demonstrations Prince Metternich resigned, and was soon after on his way to London; and an imperial proclamation was issued, declaring the abolition of the censorship of the press, the establishment of a national guard, and the convocation of a national assembly. These measures, however, as well as the nomination of a new ministry, were far from sufficing to arrest the popular movement, encouraged and led on by the students and other members of the university. The national guard just called into being, along with the academic legion, formed themselves into a permanent committee, and dictated laws to the Government. On the 17th of May, Ferdinand, accompanied by the empress and the members of his family, secretly quitted the palace, and fled to Innsbruck. An attempt to dissolve the academic legion caused an outbreak on the 25th, and the streets were barricaded; but no fighting took place, for the ministers yielded to the demands of the rioters, and gave up their design. A committee of citizens, national guards, and students, which was formed for the preservation of peace and order, was legalised by the prime minister, and assumed the authority of the Government. In the meantime the revolutionary spirit was manifesting itself in other parts of the empire. In Italy the inhabitants of

Revolution of 1848.

Milan and Venice rose against their rulers, and expelled the Austrian troops. This was followed by a general rising throughout Lombardy and Venice. The insurgents found an ally in Charles Albert, king of Sardinia, who came with an army to their assistance, and declared war against the empire. At first he succeeded in driving the Austrians back to the northern frontier of Italy; but General Radetzky, having received reinforcements, vanquished him in several engagements, and compelled him to flee to his own dominions, and conclude a truce with the victors. This was followed by the reconquest of Milan and the whole of Lombardy. Venice withstood the besieging army of the Austrians for some months, but was at length obliged to surrender. In Bohemia the Czechs or Slavonic party determined to obtain redress against the Germanising measures of the Government, and forwarded a petition to the emperor, demanding a united and independent national assembly for Bohemia and Moravia, independent municipal institutions, and an equal share in public offices with the German part of the population. An evasive answer was returned, and the citizens of the capital rose in insurrection. A national assembly of delegates of the Slavonians in all parts of the empire was summoned to meet at Prague. Three hundred made their appearance, and the assembly was opened in the beginning of June. The efforts of the military to maintain peace excited the enmity of the citizens, and they petitioned for the removal of the commander, Prince Windischgrätz. Meanwhile a collision took place between the Slavonic militia and the regular troops. The Germans joined with the military, and the insurrection raged for five days; the town was bombarded and taken, and the leaders dispersed or taken prisoners.

In Hungary the National Diet had passed measures in favour of a responsible ministry, a perfect equality of civil rights, religious toleration, the formation of a national guard, and abolition of the censorship of the press. The emperor gave his consent to these measures; but a strong Austrian party in the country, chiefly Slavonians, was opposed to them, and, instigated and supported by the Austrian Government, they broke out in open revolt. Jellachich, the ban or governor of Croatia, was the leader of the insurgents, and collecting an army of 65,000 men, he marched on towards Pesth. An army was speedily raised by the Hungarians to meet him, and a battle was fought within 25 miles of the capital on 29th September, in which Jellachich was beaten. The emperor now openly declared against the Hungarians, annulled the decrees of the Diet, suspended the civil authorities, and appointed Jellachich commander of the army. The Diet, denying the authority of the emperor, organised a committee of safety, and elected Kossuth president. This was equivalent to a declaration of war, and an Austrian army was ordered out against them. The people of Vienna, sympathising with the Hungarians, rose in arms, when the garrison of that city departed for Hungary (6th October). A deputation waited on the minister of war, Latour, demanding their recall, and on his refusal they took the arsenal by storm, and murdered him. The National Diet, which had met on the 22d of July, now declared its sittings permanent, and elected a committee of public safety. It sent an address to the emperor asking for a new ministry, the revocation of the edict against the Hungarians, the dismissal of Jellachich, and an amnesty for the rioters. The emperor, who had returned from Innsbruck to Vienna in June, returned an evasive answer, and fled to Olmütz. The people in the capital armed themselves under the leadership of General Bem, and prepared to resist the impending attack of the army. The garrison, after having retired outside the limits of the city, was joined by Jellachich's horde of Croatians and by the army of Windischgrätz. On 23d October, an army of 100,000 men appeared before Vienna, and the city was summoned to surrender. This the people refused to do, and the attack was commenced on the 28th, when the city was set on fire in many places. The next day a part of the suburbs was taken, and the leaders began to think of surrendering when the news of a Hungarian army hastening to their relief inspired them with fresh courage. This force, however, was attacked and put to flight by Jellachich (30th October), and next day the city was taken by storm, after a desperate struggle, which was attended with immense slaughter. On 22d November a new ministry was formed, of which Prince Schwarzenberg was president; and on 2d December the Emperor Ferdinand was induced to abdicate the throne. His brother, Francis Charles, who was his legal successor, likewise renounced his right in favour of his son, Francis Joseph, who was proclaimed emperor under the title of Francis Joseph I.

The war in Hungary was renewed by Windischgrätz, 1849.
who crossed the Leitha, and after several successful engagements entered the capital of that country (January 1849), the Hungarian Government and one division of the army having departed eastward to Debreczin, while the other under Görgei retired northward towards Waitzen. The Austrian general, instead of pursuing them, remained inactive for seven weeks at Pesth, and thus afforded them time to organise. In Transylvania General Bem gained a decisive victory over the Austrians in that territory, and also defeated and put to flight a Russian force that had come to their assistance. At length Windischgrätz moved forward towards Debreczin, and met the Hungarians at Kapolna, where an obstinate and bloody but indecisive battle was fought (26th February). Next day the Austrians, having received reinforcements, renewed the fight, and the Hungarians were obliged to retire. The latter having recruited their forces, another obstinate battle was fought near Gödölö (5th April), in which the Austrians were defeated, as they were in several subsequent engagements, so that they were compelled to abandon the capital and recross the Danube, leaving a small garrison at Buda, which afterwards surrendered. Had the victorious army now marched on to Vienna they would doubtless have succeeded in bringing the Austrians to terms; but disputes among the rulers and dissensions among the generals prevented such a course. In June Prince Paskewitch crossed the Galician frontier at the head of a Russian army of 130,000 men; and General Haynau, who now had the command of the Austrian troops, was joined by a Russian corps under General Palutin. The Hungarians were unable to contend against these forces, and had again to leave their capital, the seat of the Government being transferred to Szegedin. Driven from this place, the army made a stand at Temesvar, but were defeated with great slaughter (9th August), and again, two days later, at Arad. On 13th August the Hungarian general, Görgei, who had been named dictator, surrendered to the Russians. Hungary was now treated as a conquered country, and the greatest cruelties were practised against the people by the Austrian general, Haynau. The military and parliamentary leaders were shot or hanged, and the prisons filled with unhappy victims. In the meantime the war in Italy was renewed by the king of Sardinia. He was, however, defeated at Mortara (21st March) by the Austrian general, Radetzky, and again at Novara (23d March), when he abdicated in favour of his son, Victor Emmanuel, with whom a peace was concluded. Venice held out against the Austrians till 23d August, when it was forced to surrender.

The congress which, since the final struggle in Vienna, had been adjourned to Kremsier, was dissolved (March 4,

1849), and a constitution promulgated by the free will of the emperor. At this time efforts were made in the German National Assembly at Frankfort to form Germany into one integral empire, excluding Austria, the imperial crown being offered to the king of Prussia. This was violently opposed by the Austrian Government, and though the king of Prussia did not venture in the face of this opposition to accept the imperial crown, he concluded a treaty with the kings of Saxony and Hanover (May 1849), with the view of forming a strict union with the different states of the German confederacy to the exclusion of Austria. To this treaty the majority of the lesser states afterwards acceded, and a diet was convened at Erfurt (May 1852), under the presidency of Prussia, for the reorganisation of Germany. Austria, to counteract the efforts of her rival, invited the different states to send their representatives to Frankfort, where she assumed the lead. The legality of the assembly was at once acknowledged by Bavaria, and Saxony and Hanover were subsequently gained over to it. While matters were in this state disturbances arose in Hesse-Cassel. The margrave invoked the assistance of Austria, while the people looked for aid to Prussia. Having received the authority of the diet at Frankfort, Austria sent an army into Hesse, where they were confronted by another army from Prussia, and an immediate commencement of hostilities was looked for, but this was averted by a conference held at Olmütz, when Prussia acknowledged the right of Austria to enter Hesse. Soon after this Austria and Prussia convoked a congress of all the states at Dresden, where it was agreed that the final settlement of the affairs of the confederacy should be submitted to the decision of the diet at Frankfort. Austria now proposed to the diet that all her provinces, including Hungary and Lombardo-Venetia, should be included in the German confederacy, but this bold proposal failed of acceptance.

Austria now made strenuous efforts to develop the resources of the monarchy by encouraging agriculture, industry, and commerce. The land was freed from the burdens of feudalism, taxes were removed, new roads were formed, and railways were constructed. A new tariff was adopted (July 1851), and negotiations were entered into with the other German states for a complete customs' union with the Zollverein, but this was strongly opposed by Prussia and several of the other states in the union. A commercial treaty, however, was, after considerable negotiation, concluded between Austria and the Zollverein (19th February 1853). The liberal concessions that had been made by the Government were rapidly disappearing, a rigorous military system of rule was being introduced, and centralisation was taking the place of the old provincial system. On the 1st of January 1852 it was announced that the constitution and fundamental rights were abolished, the ministers were declared responsible only to the emperor, trial by jury was set aside, the censorship of the press was again in operation. The influence of the Roman Catholic clergy and the Jesuits was also re-established. A popular outbreak occurred in Milan (6th February 1853), when a number of the military were killed, but it was speedily suppressed. An attempt was made to assassinate the emperor in Vienna by a young Hungarian (18th February). In the quarrel between the Montenegrins and the Porte, Austria sided with the former, and Count Leiningen was sent to Constantinople (February 1853) to demand the redress of their grievances, which was granted. About this time Russia demanded the protectorate of the Greek Christians in Turkey, and this being denied, her troops crossed the Pruth and occupied the principalities of Moldavia and Wallachia (July 1853). Austria took a leading part, along with France and England, in condemning these proceedings and in endeavouring to bring about peace. She also gave the Western powers to believe that she would actively co-operate with them in the defence of Turkey, but afterwards fell back upon vague promises, and on April 20, 1854, entered into an alliance with Prussia, by which the two powers guaranteed each other's dominions from attack, and pledged themselves only to take an active part in the war when the interests of Germany appeared to be endangered. On June 14th Austria agreed with Turkey to occupy the Danubian principalities with an armed force, and by the end of August she had a large army there, which virtually brought the war on the Danube to an end. Austria still continued to use her exertions to bring about peace, and with this view a conference was opened at Vienna in March 1855, but the representatives of the several powers were unable to agree upon a basis. After the fall of Sebastopol she again renewed her efforts, and having ascertained the terms on which the Western powers would be prepared to treat, she sent Count Esterhazy to St Petersburg to lay them before the czar, by whom they were accepted, and a treaty of peace was signed at Paris, 31st March 1856.

In August 1855 the emperor signed a concordat with the Pope, giving the church greater power in the country than it had ever possessed before. The clergy were to have unlimited control over all ecclesiastical matters and matters connected with education, and were to enjoy free communication with Rome without the intervention of the civil power. The Government now seemed desirous of relaxing somewhat their restrictions, and of making the people forget the troubles of 1848 and 1849. The military rule was made less strict, and a general amnesty was proclaimed for political offences (12th July 1856). The emperor visited Italy in the end of 1856 and Hungary in May 1857, but the remembrance of past wrongs was still alive in the minds of the people, and he was everywhere received with the greatest coolness. Austria was opposed to the union of the Danubian principalities, and for some time refused to evacuate them, but at length (March 1857) her troops were recalled.

Sardinia had frequently remonstrated with Austria concerning her policy in Italy, while Austria, on the other hand, complained of the attacks made upon her by the Sardinian press. A growing coolness had also sprung up between Austria and France on this subject, which reached its climax when the French emperor said to the Austrian minister, M. Hübner, at the levee on the 1st of January 1859, "I regret that our relations with your Government are not so good as they were; but I request you to tell the emperor that my personal feelings for him have not changed." The preparations for war were carried on with the greatest activity by Austria, France, and Sardinia. England sent Lord Cowley to Vienna to endeavour to arrange differences, but without success. Russia proposed a congress of the five great powers, and this was agreed to, but Austria demanded the disarmament of Sardinia previous to the congress, which the latter declined to agree to, and both sides prepared for war. Austrian troops poured into Italy, France was concentrating her forces at Toulon, and Garibaldi was organising a corps of Italian volunteers. The Austrians crossed the Ticino (April 26), and the French troops were marched into Italy. Napoleon left Paris on the 10th of May, and reached Genoa on the 12th, where he was next day joined by Victor Emmanuel. The first serious encounter took place at Montebello (May 20), when a strong body of Austrians was, after a desperate resistance, defeated and put to flight by a body of French troops. The Austrians again suffered a severe defeat at Palestro (May 31). On 4th June the battle of Magenta was fought, in which the Austrians were, after a long and desperate conflict, defeated and put to flight by the combined army of the French and Sardinians, under the command of the

1859.

War wit France a Sardinia

Emperor Napoleon in person. The Austrians fought with great bravery and determination, but were not well officered, and the arrival of General M'Mahon with his troops at an opportune moment decided the battle against them. They had about 75,000 men in the field, while the allies numbered about 55,000. The latter lost about 4000 men in killed and wounded, the former about 10,000, besides 7000 prisoners. Next day the inhabitants of Milan rose in insurrection, and the garrison fled. Pavia was evacuated on the 7th, and on the 8th the fortified position of Melegnano was taken after three hours' hard fighting. The same day the allied monarchs made their triumphal entry into Milan. One stronghold after another now fell into the hands of the conquerors. The defeated army retreated to the further bank of the Mincio, where it was reorganised, and the emperor himself assumed the command. It then recrossed the Mincio, and took up a position near the village of Solferino. Here the allies came up to it, and both sides prepared for battle. The Austrian army numbered about 170,000 men, while the allied troops were not less than 150,000. The battle commenced early in the morning of the 24th June, and continued till late in the afternoon. The Austrian line extended for nearly 12 miles. The right and left wings of the Austrians were for some time successful, while Napoleon was using every effort to break their centre. In this he was at length successful, and the wings were then obliged to retire in order that they might not be overflanked. The French lost in killed and wounded 12,000 men, the Sardinians 5000, and the Austrians 20,000, besides 7000 prisoners. The Austrians now abandoned the line of the Mincio, and fell back upon Verona. The allies crossed the Mincio, Peschiera was invested, and great preparations were made on both sides for renewing the contest. While all Europe was in the expectation of another great battle, news arrived that an armistice for five weeks had been agreed to; and on 11th July the two emperors met at Villafranca, and agreed to terms of peace. A conference was afterwards held at Zürich, and a treaty drawn up and signed (10th November 1859). By it Austria gave up Lombardy, with the exception of the fortresses of Mantua and Peschiera, to Napoleon, who was to hand it over to the king of Sardinia; Italy was to be formed into a confederation under the presidency of the Pope, and Austria was to be a member on account of Venetia; and the princes of Tuscany and Modena were to have their possessions restored to them.

1860. In March 1860 the emperor, by patent, enlarged the number and powers of the Reichsrath or council of the empire, and on 21st October promulgated a new constitution, in which he declared the right to issue, alter, and abolish laws, to be exercised by him and his successors only with the co-operation of the lawfully assembled diets and of the Reichsrath. The things to be settled with the co-operation of the Reichsrath were all legislative matters relating to the rights, duties, and interests of the several kingdoms and countries, such as the laws connected with the coinage, currency, public credit, customs, and commercial matters. This was followed by proposals of
1861. similar changes for Hungary; and, on 27th February following, it was decreed that their former constitutions should be restored to Hungary, Croatia, Slavonia, and Transylvania. At last-mentioned date a fundamental law was also promulgated for the representation of the empire by a Reichsrath, composed of two bodies, a house of peers and a house of deputies, and declaring the constitution and functions of each. It was declared to be the earnest wish of the Government that hyper-centralisation should be avoided. On 1st May the new Reichsrath was formally opened by the emperor at Vienna, when he declared his conviction "that liberal institutions, with the conscientious introduction and maintenance of the principles of equal rights of all the nationalities of his empire, of the equality of all his subjects in the eye of the law, and of the participation of the representatives of the people in the legislation, would lead to a salutary transformation of the whole monarchy." Hungary, Croatia, Slavonia, and Transylvania declined to send representatives, claiming to have constitutions and rights distinct from the empire. The Reichsrath sat till the close of 1862, occupying itself chiefly with ecclesiastical affairs, the state of education, personal liberty, and the laws relating to the press, commerce, feudal tenures, &c. In 1863 the emperor of Austria invited the different potentates of Germany to meet him at Frankfort, in order to determine upon a scheme of reform for their common country. They almost all responded to the invitation except the king of Prussia, and the congress was opened (August 16) by a speech from the emperor. The proceedings, however, did not result in any important change, owing in great measure to the want of sympathy from Prussia.

The death of Ferdinand VII., king of Denmark (15th November 1863), gave rise to a general ferment in Germany on the subject of the duchies Schleswig, Holstein, and Lauenburg. To the Germans a united fatherland had long been a favourite idea, and they now saw a step towards its accomplishment. Notwithstanding the treaty of London (8th May 1852), which fixed the succession to the Danish crown, and was signed by Austria and Prussia, they denied the right of the new king, Christian IX., to the duchies, and laid claim to them as part of Germany. To enforce their claim the diet determined that they should be occupied by an armed force, and Saxony and Hanover were directed to enter and take possession of Holstein. This was done without their coming into hostile collision with the Danish troops, who retired to Schleswig (December 1863). Soon after this, however, Austria and Prussia gave notice that they, as the chief powers in Germany, intended to take upon themselves the carrying on of the war. Hostilities commenced (1st February 1864) when Austrian and Prussian troops crossed the Schleswig frontier. Denmark had trusted to England and France coming forward to maintain the conditions of the treaty of 1852; but these powers remained passive, and the Danes, after a short but heroic stand, were forced to succumb. An armistice was concluded (1st August), and a treaty of peace was eventually signed at Vienna (30th October), by which Denmark made over Schleswig, Holstein, and Lauenburg to Austria and Prussia.

But Austria speedily suffered terrible retribution for the part she had taken in this affair. By inducing Austria to join with her, Prussia succeeded in removing part of the odium of the proceeding from herself, and she also succeeded in obtaining the aid of a rival power to secure territories which she had previously determined to appropriate as her own. The acquired territory naturally lay very convenient for Prussia, and Austria would have willingly enough given up her claim on it if Prussia had agreed to grant her a territorial equivalent in some other quarter of her dominions. This the latter power declined to do, but would readily have consented to a pecuniary compensation. A convention was therefore held at Gastein (August 1865), which brought about a temporary understanding. Prussia was to receive Lauenburg on payment of a sum of 1,500,000 thalers, while Austria was to have the administration of affairs in Holstein, and Prussia in Schleswig. Austria, however, was desirous of the formation of the duchies into a separate state, and supported the claims of the duke of Augustenburg to them. This was strenuously opposed by Prussia, who regarded the public meetings that were permitted to be held in Holstein in support of this as a breach of agreement. Austria referred

the question to the Frankfort diet, which decided in favour of the duke. Matters were now approaching a crisis. Prussia had long looked with jealousy upon the power of Austria, and considered a war with that country for the supremacy of Germany as sooner or later a necessity. The German people had for some time felt that there was not room for two great powers,—each too great to submit to the other,—one or other must give way before the country could obtain its proper place and influence in Europe.

1866. While both powers were professing the utmost desire for peace, each was actively preparing for war. Prussia entered into an alliance with Victor Emmanuel (27th March 1866), the latter undertaking to declare war against Austria as soon as Prussia commenced hostilities, while the former engaged to secure Venetia for her Italian ally. In the beginning of May orders were issued by the emperor of Austria for putting the whole army upon a war footing, and for concentrating a portion of it upon the Bohemian and Silesian frontiers; and about the same time the Prussian cabinet issued orders to fill up to the war strength the different branches of the service. On 7th June the Prussian troops entered Holstein, and compelled the Austrians to retire, which they did without bloodshed.

War with Prussia.

Austria was in an unprepared state when the war actually broke out, but the Prussian forces, on the other hand, were thoroughly equipped. The Austrian army in the north amounted to 247,000 men, besides the Saxon army at Dresden of 24,000, in all 271,000. The Prussian force consisted of three armies: the first, under the command of Prince Frederick Charles, consisted of 93,000 men, and was destined for Saxony and Bohemia; the second, under the crown prince, numbered 115,000 men, and was to operate in Silesia; while the third, or army of the Elbe, under General Herwarth, consisting of 46,000 men, was to march on the right flank of the first army, making in all 254,000 men, besides reserve corps of 24,300 men stationed at Berlin. General Benedek was appointed commander-in-chief of the Austrian army, and his forces were distributed along the frontier that separates Moravia from Saxony and Silesia. On the 16th of June the Prussians entered Saxony, and marched upon Dresden, the Saxon army retiring to join the Austrians. On the 18th the Austrians entered Silesia, and the same day the Prussians took possession of Dresden. The three Prussian armies now advanced into Bohemia, and endeavoured to concentrate in the direction of Gitschin. On June 26th an engagement took place between some companies of the first army and a body of Austrians at Podol, in which the latter were defeated, while, at Hühnerwasser, the advanced guard of the Elbe army attacked some Austrian troops and drove them back towards Münchengrätz. Here, on the 28th, a severe struggle took place between the Prussians and the Austrians, supported by the Saxons, but the latter were ultimately driven back in the direction of Gitschin. In the meantime the second army, under the crown prince, had to march through the long and narrow passes of the mountains lying between Silesia and Bohemia. On the 27th one of the corps of this army, under General Steinmetz, engaged an Austrian force under General Ramming, and after a severe contest began to give way, but the crown prince coming up, the Austrians were driven back. The same day another corps of this army took possession of Trautenau, but were attacked by the Austrians under General Gablenz, and sustained a repulse. Both sides having received reinforcements, the action was renewed next day at Soor, when victory ultimately declared for the Prussians. At Skalitz, on the 28th, the Prussians, under Steinmetz, were attacked by the Austrians under Archduke Leopold, but the latter were defeated, and the town taken by storm. It is said that on this occasion the archduke had disobeyed positive orders, which were on no account to make an attack. On the 29th, two divisions of the first army, under Generals Tümpling and Werder, defeated the Austrians under Count Clam Gallas, at Gitschin, and took the town. The count, who occupied a strong position here, had orders not to attack the enemy, but these he had disobeyed, and the consequence was that Benedek, who had taken up a strong position at Dubenetz to oppose the army of the crown prince, found himself at once in a most dangerous situation, and was obliged to retreat towards Königgrätz. On the same day bodies of Austrians were defeated at Königinhof and Schweinschädel. In these various engagements the Austrians lost in all from 30,000 to 40,000 men. Both sides now concentrated their forces in the direction of Königgrätz, and prepared for a general engagement. On June 30 the king of Prussia joined the army, and the battle of Königgrätz, or Sadowa, was fought on the 3d of July. The Austrians numbered about 220,000, and the Prussians probably about 240,000. The battle was long and well contested, both sides fighting with the greatest determination and bravery; but at length the Austrians were broken, and obliged to retire. The Prussians lost 359 officers and 8794 men, while the Austrians and Saxons lost in all about 44,200 men, of whom 19,800 were prisoners. This terminated what has been sometimes called the *Seven Days' War*. The Austrians retreated to Zwittau and afterwards to Olmütz. A portion of the Prussians went in pursuit, but the king, with an army of upwards of 100,000 men, marched on towards Vienna, and reached Nikolsburg, July 18. After the battle of Königgrätz, the emperor, seeing the disastrous state of his affairs, resolved to cede Venetia to the Emperor Napoleon, so as to be able to bring his army in Italy against the Prussians, and he also expressed his willingness to accept the mediation of the latter to bring about a peace. The Archduke Albert, who had the command of the army in Italy, with which he had inflicted a severe defeat on the Italians at Custozza, was recalled to take the chief command in place of Benedek. An armistice, however, was agreed upon through the mediation of France (22d July). The preliminaries of peace were signed at Nikolsburg (26th July), and negotiations were afterwards carried on at Prague, where a treaty was signed (23d August). By this treaty Austria gave up to the kingdom of Italy Venetia and the fortresses of the quadrilateral, namely, Peschiera, Mantua, Verona, and Legnano; recognised the dissolution of the late German Confederation, and consented to a new formation of Germany, in which she should have no part; gave up all claim to the duchies of Holstein and Schleswig; and agreed to pay a war indemnity of 40,000,000 thalers, less 20,000,000 allowed her on account of the duchies.

Having thus obtained peace, the emperor now turned his attention to home affairs. Hungary was still in a very troubled and dissatisfied state. We have seen that she declined to send representatives to the Reichsrath, insisting on her right to self-government, and refusing to have anything else. The plan of opposition she adopted was that of passive resistance, by the non-payment of taxes. At length, at the opening of the Hungarian diet at Pesth by the emperor in person, on December 14, 1865, he recognised the necessity of self-government for Hungary so far as it did not affect the unity of the empire and the position of Austria as a great European power. He also recognised the Pragmatic Sanction as the basis on which a settlement of their difficulties was to be sought. At the opening of the diet on 19th November 1866, an imperial rescript, signed by the emperor, was read, in which he promised, by the appointment of a responsible ministry, and the restoration of municipal self-government, to do justice to the constitutional demands of the Hungarians. In the end of

1866, Baron Beust, who had previously been prime minister of Saxony, and was not only a foreigner but a Protestant, was made foreign minister. He subsequently became prime minister and chancellor of the empire. In the spring of 1867 the emperor summoned the Reichsrath to assemble at Vienna to deliberate upon various important measures,—the proposed amendments in the Hungarian constitution, the question of ministerial responsibility, the sending of delegates to assemblies, the extension of the constitutional self-government of the different provinces, the reorganisation of the army, the improvement of the administration of justice, and the promotion of the economical interests of the country. It was opened by the emperor in person on May 22, and in his speech on the occasion he earnestly recommended to their attention these subjects. "To-day," he said, "we are about to establish a work of peace and of concord. Let us throw a veil of forgetfulness over the immediate past, which has inflicted deep wounds upon the empire. Let us lay to heart the lessons which it leaves behind, but let us derive with unshaken courage new strength, and the resolve to secure to the empire peace and power." On 8th June the emperor and empress were crowned king and queen of Hungary at Pesth amid great public rejoicings, on which occasion full pardon was given for all past political offences, and full liberty to all offenders residing in foreign countries to return. Many important and liberal measures were discussed and carried in the Reichsrath; in particular, marriage was made a civil contract, and the perfect equality of believers of different creeds was recognised. On 25th May 1868, the civil marriage bill received imperial assent, and on 30th July 1870 the concordat with Rome was declared to be suspended in consequence of the promulgation of the doctrine of Papal infallibility. This last measure introduced a very beneficial change in the relations between Austria and the kingdom of Italy, and has brought about more sympathy and cordiality between these two states than formerly existed.

For some years the Government had much difficulty in settling the law of elections so as to secure the due representation of the different races and classes of the people in the Reichsrath. On 6th March 1873 a reform bill was passed by the lower house, taking the election of members of the Reichsrath out of the hands of the provincial diets and transferring it to the body of the electors in the several provinces, thus substituting direct for indirect election. In April it passed the upper house and received the imperial assent. This measure was hailed with great satisfaction, and has established the government upon a much broader and more secure basis. The session of the new Reichsrath was opened by the emperor in person on November 5. In the same year a great exhibition of the industries of all nations was held at Vienna. It was opened on May 1 by the emperor, and attracted to the capital, among others, the prince of Wales, the czar of Russia, the emperor and empress of Germany, the king of Italy, and the shah of Persia. On 2d December the twenty-fifth anniversary of the emperor's accession to the throne was celebrated amid great rejoicings in Vienna, having been celebrated three days before in Pesth. The emperor and empress were present on both occasions, and everywhere met with an enthusiastic reception. In the spring of 1874 a bill for the abolition of the concordat was introduced by the Government, and measures for restricting the powers of the clergy passed both houses. In his speech at the opening of the Reichsrath on 5th November of that year, the emperor said that by the system of direct popular elections the empire had obtained real independence, and exhorted the members to work with united energy at the solution of the greatest of their tasks, the uniting of the people of Austria, so that she might become a powerful state, strong in ideas of justice and liberty.

S. Cooke, 1874. (D. K.)

AUTOCHTHONES, in *Greek Mythology*, the first human beings who appeared in the world, and who, as their name implies, were believed to have sprung from the earth itself. Instead of one pair as the first parents of the whole race, each district of Greece had its own autochthones, who, according to the prominent physical features of the neighbourhood, were supposed to have been produced from trees, rocks, or marshy places, the most peculiar, and apparently the most widely-spread belief being that which traced the origin of mankind to the otherwise unproductive rocks. Whether the first appearance of mankind was regarded as having been simultaneous in the various districts or not, at what time or times such appearance was made with reference, for example, to the origin of the gods who also had sprung from the earth (Pindar, *Nem.* vi. 1; Hesiod, *Works and Days*, 108), and whether the first men possessed the full human form, are questions which there is no material to answer satisfactorily. On the last point it is to be observed that Erysichthon at Athens was said to have had legs in the form of serpents, and that this is taken to denote his origination from a marshy place. Similarly the earth-born giants, who made war against the gods, had legs in the form of serpents. In Thebes, the race of Sparti were believed to have sprung from a field sown with dragons' teeth. The Phrygian Corybantes had been forced out of the hill-side like trees by Rhea, the great mother, and hence were called δενδροφυεῖς. But whatever the primitive form of men was believed to have been, it is clear from Æschylus (*Prometheus*, 447, *foll.*) that they were supposed to have at first lived like animals in caves and woods, till by the help of the gods and heroes they were raised to a stage of civilisation. The practice of describing legendary heroes and men of ancient lineage as "earth-born," γηγενεῖς, strengthened greatly the doctrine of autochthony, and nowhere so much as in Attica.

AUTO-DA-FE (*Act of Faith*), a public solemnity of the Inquisition in Spain and Portugal, at which the sentences of the court were read; those who were declared innocent were formally absolved, and the condemned were handed over to the secular power for punishment. The day chosen was usually some Sunday between Trinity and Advent. The first auto-da-fe was held by Torquemada at Seville in 1481; the last was probably that mentioned by Llorente, the historian of the Inquisition, as having been solemnised in Mexico in 1815. See INQUISITION.

AUTOGRAPH (αὐτός and γράφειν), that which is written with a person's own hand, an original manuscript as opposed to an *apograph* or copy, is used to designate either a whole document (*e.g.*, a letter) or a signature only. The latter is perhaps the more common use of the term. The interest attaching to the possession of autographs of distinguished men, which has created a new branch of industry, is partly historical, partly psychological. The signatures or original manuscripts are interesting and valuable elements in the representation of the life of any individual; and it has been thought that from the

autograph some conclusions might be drawn as to the mental characteristics of the writer. It is doubtless true that temperament will in some degree affect handwriting, but the conditions to be taken into account are so numerous and variable that the attempt to infer the one from the other seems practically hopeless. Poe, in his ingenious "Chapter on Autography" (*Works*, Ed. Ingram, vol. iv.), speaks very strongly on this subject. He thinks that none but the unreflecting can deny "that a strong analogy does generally and naturally exist between every man's chirography and character," and to support his statement compares the signatures and mental characteristics of a large number of contemporary American writers. In many cases, however, he is obliged to confess that no inference whatever can be drawn, in some others the analogy is extremely forced, and in others, again, the knowledge of the writer's character has evidently furnished the key for the interpretation of the handwriting. The value placed by an *amateur* on any autograph will, of course, vary with the celebrity of its author and the scarcity of genuine specimens. The taste for collecting autographs is not confined to modern times; many large collections, *e.g.*, those of Loménie de Brienne, of Lacroix du Maine, and others, were formed in the 16th century, and during the same period we know that albums used to be carried about for the purpose of obtaining the signatures of famous personages. One of these albums preserved in the British Museum is of date 1578. There are at present many valuable public and private collections, while state papers and archives, of course, contain a rich harvest of royal and noble signatures. Fac-similes of original manuscripts appear first to have been printed in Forbes's *Full View of the Public Transactions in the Reign of Queen Elizabeth*, 1740-41; and soon after, several were given in Fenn's *Original Letters from the Archives of the Paston Family*, 1787.

The following are, perhaps, the most useful works on the subject:—J. G. Nichol's *Autographs of Royal, Noble, Learned, and Remarkable Personages conspicuous in English History, from the Reign of Richard II. to that of Charles II.*, Lond. 1829; *Autographic Mirror*, 1864, *sqq.*: Netherclift, *Handbook of Autographs*; Phillips and Netherclift, *Autographic Album*; Simms, *Autographic Souvenir*; Netherclift and Simms, *Autographic Miscellany*; *Isographie des Hommes Célèbres*, 4 vols. 1829-43; *Iconographie des Contemporains*, 2 vols. 1823-32; Feuillet de Conches, *Causeries d'un Curieux*, 3 vols. 1862-64; Lescure, *Les Autographes*, 1865; Günther und Schulz, *Handbuch für Autographensammler*, 1856; *Sammlung historisch berühmter Autographen*, 1846; *Autographen Album zur 200 jähr. Gedächtnissfeier des Westphälischen Friedens-schlusses*, 1848.

AUTOLYCUS of PITANE, in Æolis, was one of the earliest Greek writers on mathematics and astronomy. As he is said to have given instruction to Arcesilaus, he probably flourished about the middle of the 4th century B.C. His extant works consist of two treatises; the one, *περὶ κινουμένης σφαίρας*, contains some simple propositions on the motion of the sphere, the other, *περὶ ἐπιτολῶν καὶ δύσεων*, in two books, discusses the rising and setting of the fixed stars. Neither treatise is of much scientific value. There are several Latin versions of Autolycus, and a French translation by Forcadel, 1572.

AUTOMATON (from *αὐτός*, self, and *μάω*, to seize), a self-moving machine, or one in which the principle of motion is contained within the mechanism itself. According to this description, clocks, watches, and all machines of a similar kind, are automata, but the word is generally applied to contrivances which simulate for a time the motions of animal life. If the human figure and actions be represented, the automaton has sometimes been called specially an *androides*. We have very early notices of the construction of automata, *e.g.*, the tripods of Vulcan, and the moving figures of Dædalus. 400 years B.C., Archytas of Tarentum is said to have made a wooden pigeon that could fly; and during the Middle Ages numerous instances of the construction of automata are recorded. Regiomontanus is said to have made an iron fly, which would flutter round the room and return to his hand, and also an eagle, which flew before the Emperor Maximilian when he was entering Nuremberg. Roger Bacon is said to have forged a brazen head which spoke, and Albertus Magnus to have had an androides, which acted as doorkeeper, and was broken to pieces by Aquinas. Of these, as of some later instances, *e.g.*, the figure constructed by Descartes and the automata exhibited by Dr Camus, not much is accurately known. But in the 18th century, Vaucanson, the celebrated mechanician, exhibited three admirable figures,—the flute-player, the tambourine-player, and the duck, which was capable of eating, drinking, and imitating exactly the natural voice of that fowl. The means by which these results had been produced were clearly seen, and a great impulse was given to the construction of similar figures. Knauss exhibited at Vienna an automaton which wrote; a father and son named Droz constructed several ingenious mechanical figures which wrote and played music; Kaufmann and Maelzel made automatic trumpeters who could play several marches. The Swiss have always been celebrated for their mechanical ingenuity, and they construct most of the curious toys, such as flying and singing birds, which are frequently met with in industrial exhibitions. The greatest difficulty has generally been experienced in devising any mechanism which shall successfully simulate the human voice. No attempt has been thoroughly successful, though many have been made. The figure exhibited by Fabermann of Vienna is, perhaps, as yet the best. No notice of automata can be complete without at least a reference to Kempelen's famous chess player, which for many years astonished and puzzled Europe. This figure, however, was no true automaton, although the mechanical contrivances for concealing the real performer and giving effect to his desired movements were exceedingly ingenious.

AUTUN, the capital of an arrondissement of the same name in the department of Saône and Loire, in France, is picturesquely situated on the declivity of a hill, at the foot of which flows the Arroux. It is one of the most ancient towns of France; and when Cæsar invaded Gaul it was the most important of the Ædui. Its name was then Bibracte, but being afterwards much improved and embellished by Augustus it took that of Augustodunum. In the later days of the Roman empire it was a flourishing city, and consequently attracted the barbarian bands. It was successively plundered and burned by the Vandals in 406, the Burgundians in 414, the Huns in 451, the Franks in 534, the Saracens in 739, and the Normans in 895. It was burned by the English in 1379, and besieged in 1591 by D'Aumont. Yet in spite of all these disastrous events, its former greatness is attested by many Roman and other remains, among which are large masses of its ancient walls, two gates in admirable preservation, called the *Porte d'Arroux* and the *Porte Saint-André*, the walls of the so-called temple of Janus, and a pyramid in the neighbouring village of Couard, in which some recognise a monument to Divitiacus. The cathedral is a structure of the 11th and 12th centuries, and is surmounted by a remarkable spire of the 15th. Autun is the seat of a bishopric, and has a college, a diocesan seminary, a museum, which is very rich in medals and other minor antiquities, a library, a theatre, &c., with tribunals of primary jurisdiction and commerce. It has manufactures of cotton goods, hosiery, carpets, leather, and paper, with a considerable trade in timber, hemp, and cattle. Population in 1872, 11,684.

AUVERGNE, a district, and formerly a province, of France, corresponding to the departments of Cantal and Puy-de-Dôme, with the arrondissement of Brioude in Haute-Loire. It is divided into Lower and Upper by the River

Ruc; the distinction between the two portions being well marked by their physical features. Upper Auvergne is rugged and mountainous, and is covered with evidences of volcanic activity, while Lower Auvergne consists largely of fertile and well-watered expanses. In climate, too, there is a marked difference; the former suffering from violent extremes, and the latter enjoying a mild and equable temperature. The whole district is largely agricultural, and special attention is paid to the rearing of cattle, horses, and mules. The mountains are rich in minerals, such as iron, lead, copper, and coal; and numerous medicinal springs are scattered along their slopes. The inhabitants, who to a certain extent are the descendants of the ancient *Arverni*, are a strong, ungainly race, habituated to toilsome labour. For a long time they have been accustomed to leave their homes for the purpose of seeking their fortunes abroad, returning after they have acquired a competency. Spain was at one period a favourite resort, but the current of emigration is now principally towards Paris or the Belgian towns. In Paris alone it has been calculated that the *Auvergnats* number 50,000. They speak a distinct dialect, and are also recognised by their pronunciation. A closer resemblance to Latin, and the presence of many sounds, such as ts, tz, dj, which are foreign to ordinary French, are among the most striking features of the *patois*; the vocabulary also contains words introduced by the English at the time of their occupation of the country in the 14th century. Of the existing literature a considerable proportion is spurious. Auvergne was early raised to the rank of a countship, and passed into the hands of various families, the most important of which is known as La Tour d'Auvergne. It was finally united to the crown by Louis XIII.

Of the numerous books which have been written on this interesting province, the following may be mentioned:—Aigueperse, *Petit Dict. des personnages d'Auvergne*, 1850; Michel, *L'ancienne Auvergne*, 3 vols. fol.; Imberdis, *L'Auvergne historique*, and *Hist. des guerres rélig. en Auvergne pendant les XVI^e et XVII^e siècles*; Allard, *Les eaux thermo-minérales d'Auvergne*.

AUXENTIUS of CAPPADOCIA was an Arian theologian of some eminence. When Constantine deposed the orthodox bishops who resisted, Auxentius was installed into the seat of Dionysius, bishop of Milan, and came to be regarded as the great opponent of the Nicene doctrine in the West. So prominent did he become, that he was specially mentioned by name in the condemnatory decree of the synod which Damasus, bishop of Rome, convened in defence of the Nicene doctrine. When the orthodox emperor Valentinian ascended the throne, Auxentius was left undisturbed in his diocese, but his theological doctrines were publicly attacked by Hilarius of Poitiers. The chief source of information about him is the *Liber contra Auxentium* in the Benedictine edition of the works of Hilarius.

AUXERRE (the ancient *Autissiodurum*), a town of France, in the department of Yonne, situated on the banks of the Yonne, in a wine-producing district, and built in an antique fashion. Its cathedral is one of the finest Gothic buildings in the country, and its episcopal palace, now used as a prefecture, will bear comparison with any. It has several normal schools, a college founded by the famous Jacques Amyot (who was a native of the town, and died there in 1593), a society of agriculture, botanic garden, museum, theatre, an extensive and valuable library, &c. The Yonne is navigable from a little above the town. Besides trade in wine and in firewood, there are manufactures of cloths, druggets, serges, cotton and woollen stockings, and some considerable tanneries. Population, 15,497.

AUXONNE (formerly *Assonium, i.e., ad Sonam*, from its position on the Saône), a city of France, in the arrondissement of Dijon and department of Côte d'Or. It is strongly fortified, and possesses an old castle, an arsenal, and a school of artillery. Besides their manufactures of cloth and serges, the inhabitants carry on by the river considerable traffic with Lyons in wine, grain, and wood. Long. 5° 24′ E., lat. 47° 13′ N. Population, 5911.

AVA, the former capital of the Burman empire, lies in 21° 52′ N. lat., and 96° 1′ E. long. It is situated on the Irawadi, which is here 3282 feet broad, and which, making a bend out of its ordinary course, flows past the city on the north. On the east it has the river Myt-nge, a rapid stream 450 feet broad, which flows into the Irawadi close under its walls. From this river a canal has been dug, through which its waters flow on the south-east angle of the city, and are again brought into the same river. On the south flows the deep and rapid torrent of the Myt-tha, an offshoot of the Myt-nge, which, falling into the Irawadi, forms the defence both of the south and of the west face of the town. It is divided into the upper and lower, or the lesser and the larger town, both of which are fortified.

The brick wall that surrounds the city is 15½ feet in height and 10 feet in thickness, on the inside of which is thrown up a bank of earth, forming an angle of 45 degrees. There is a ditch round the outer wall which is inconsiderable, and in the dry season fordable in every part. The lesser town is chiefly occupied by the royal palace, the hall of justice, the council chamber, the arsenal, and the habitations of a few courtiers of distinction. A strong well-built wall of more solid construction than the outer wall of the city, and about 20 feet high, encloses the square in which these buildings are situated, and on the outside is a teak-wood stockade of the same height. The ditch which surrounds the lesser town is, moreover, deeper and broader than that of the city, and when full is not to be forded. There are, however, three causeways across, which communicate with the adjacent country. The circumference of the city, excluding the suburbs, is about 5½ miles, but over this extensive area the houses are but thinly scattered; some quarters are, indeed, wholly destitute of habitations, and have the appearance merely of neglected commons. In general the dwellings of the inhabitants are of the most miserable sort, being mere huts thatched with grass. Wretched as are such habitations to European eyes, the poorer classes are perhaps as well lodged here as in any other parts of Asia. Their sleeping-places are elevated 2 or 3 feet from the ground. Some of the houses of the chiefs are constructed of planks, and tiled; but there are not, according to Mr Crawford, more than half-a-dozen edifices built of brick and mortar. Ava, like all the other Burmese towns, is adorned with numerous temples, of which the gilded spires, rising aloft, present on a distant view of the place a splendid and imposing appearance, which is far from being realised on a nearer inspection. The largest of these temples contains two distinct edifices, one in the ancient, the other in a modern form; the former containing an image of Gautama, not of marble, as Symes supposes, but of sandstone. It is in a sitting posture, and is 24 feet in height. The head is 8 feet in diameter. There is another very large temple, and a third named the "Beautiful." The one called Maong-Ratna is of great celebrity; it is the one in which the public officers of the government take, with the most solemn forms, the oath of allegiance. The temple called Maha-mrat-muni had an addition made to it some years ago, of which Mr Crawford mentions that the numerous and richly-gilded pillars and splendid ceiling exceeded anything that was to be seen without the palace. Ava contains eleven markets or bázárs, composed of thatched huts and sheds, which, however, are well supplied with all that is necessary for the wants of the people. Besides native commodities, there are exposed in these markets the produce of China and Lao, with British cottons, woollens, glass, and earthenware. The Burman monasteries are mostly built of wood; and of those composed of more solid materials, a few ancient ones are nearly all that are to be seen. The only exception is a monastery, built some years ago by the queen, adjoining the palace—an unshapely fabric of immense size, but a very conspicuous object.

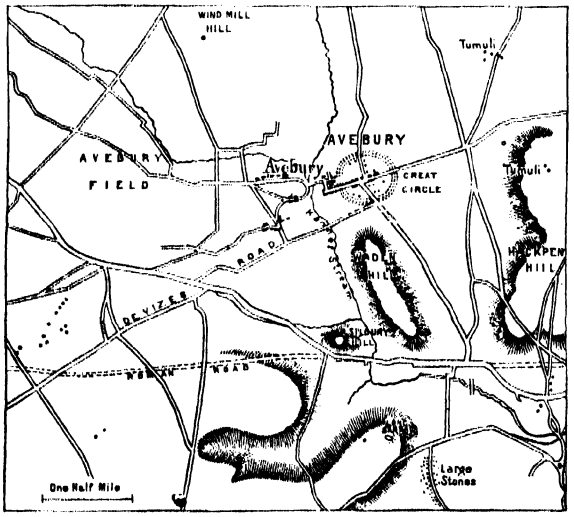
This former capital of the Burman dominions comprehends, according to the political divisions of that empire, the town of Sagaing, on the opposite shore of the Irawadi, and the town of Amarapura, 4 miles to the east. The town of Sagaing extends along the Irawadi for more than a mile and a half, but is of inconsiderable breadth. It consists of mean houses thinly scattered among gardens and orchards, the principal trees in the latter consisting of fine old tamarinds. Over the site of the town and its environs are scattered innumerable temples, some of them

old and ruinous, others modern. On the river face it has a brick wall about 10 feet in height, with parapet and embrasures like that of Ava, and extending for above half a mile along the river. Amarapura is a large place, and was formerly the capital; but Ava which was twice before the capital, was again made so in 1822. It continued to be so till 1853, when the present king, on his accession, transferred the capital to Mandalay. To each of the towns of Ava, Sagaing, and Amarapura, are attached districts, the two former of which extend 12 miles along the river, and are of equal breadth. The district of Amarapura is of equal size, so that Ava must be considered as not only the name of the former capital, but of a large district, which includes an area of 288 miles, containing, according to the most accurate estimate, 354,200 inhabitants; but the city of Ava is not supposed to contain more than 50,000 inhabitants, and, according to Mr Crawford, half that number would be nearer the truth. The place, taken altogether, affords few indications of industry or commercial enterprise.

AVALLON, a town of France, in the department of Yonne, finely situated on a granite rock, at the foot of which flows the river Voisin or Cousin. The church of St Lazare, which dates from the 12th century, is a good specimen of Burgundian Gothic. Manufactures of cloth, hats, hosiery, leather, and paper are carried on, and there is a considerable traffic in firewood, which is conveyed by the Voisin, the Yonne, and the Seine to Paris. The town was long an object of dispute between Burgundy and France, but was finally united to the crown on the death of Charles the Bold. It was pillaged by the Leaguers in 1591. Population, 6070. Long. 3° 56′ E., lat. 47° 30′ N.

AVATCHA, one of the numerous volcanoes of Kamchatka, in lat. 53° 17′ N., and long. 158° 50′ E. It rises to a height of nearly 9000 feet (Mr Kennan says 11,000), and has an extensive crater at the summit and another on its side. It was in active eruption in 1827, 1837, and 1855. About twenty miles to the south lies the village of Avatcha on a river of the same name; and in the immediate neighbourhood of the mountain is situated the little town of Petropavlovski, which contains memorials of Behring and La Pérouse, and was the scene of a desperate conflict during the Crimean War between the Russians and an invading party of the allies.

AVEBURY, a village of England, in the county of Wilts, 6 miles W. of Marlborough. It occupies the site of



Plan of Avebury.

one of the most remarkable megalithic structures in England. This consisted of a large outer circle formed of 100 stones of from 15 to 17 feet in height, and about 40 feet in circumference, enclosing an area of about 1000 feet in diameter. This circle was surrounded by a broad ditch and lofty rampart. Within its area were two smaller circles, 350 and 325 feet in diameter respectively, each consisting of a double concentric row of stones,—a stone pillar or maenhir, 20 feet high, occupying the centre of the one, and a cromlech or dolmen that of the other. A long avenue of approach, now known as the Kennet Avenue, consisting of a double row of stones, branched off from this structure towards the S.E. for a distance of 1430 yards. Few traces of this immense erection now remain—the stones having been broken down and used in the construction of the houses of the village, and for other purposes. In the vicinity are two other monuments of great importance, which may be regarded as belonging to the same group, namely, the double oval of megaliths on Hakpen Hill—Haca's pen—and the artificial mound known as Silbury Hill. The Hakpen oval was, according to Stukeley, 138 feet by 155, and had an avenue 45 feet wide stretching in the direction of Silbury Hill. This hill is due south from Avebury, and the distance from the centre of the circle to the centre of the mound is very nearly one Roman mile. Much discussion has taken place about the age and object of these constructions, the most popular theory hitherto being that which ascribed them to the Druids, and thus got rid of historic difficulties by escaping into the region of the prehistoric. Recently, Mr Fergusson has strenuously maintained that the larger circle, or Avebury proper, and Silbury Hill, commemorate the last of the twelve Arthurian battles, which was fought (520 A.D.) at Badon Hill, a name which he identifies with Waden Hill.

AVEIRO, a town of Portugal, province of Beira, the seat of a bishopric and college. It has sardine, oyster, and herring fisheries, as well as a thriving trade in oil, salt, wine, and oranges. The haven is wide and deep. Population, 6456. Long. 8° 34′ W., lat. 40° 40′ N.

AVELLA, a town of Italy, in the province of Principato Ulteriore, in a fine situation, and commanding most extensive prospects. It is distant about 20 miles from Naples, and contains 3714 inhabitants. Near it are the remains of the ancient Abella.

AVELLINO, a fortified city of Italy, in the province of Principato Ulteriore, at the foot of Mount Vergine, and 28 miles E. of Naples. It is the see of a bishop, and has a cathedral, several parish churches, a royal college, &c., with manufactories of cloth, paper, maccaroni, and sausages, and extensive dye-works. It has a considerable trade in corn, chestnuts, and hazel-nuts. The city has at various times suffered severely from earthquakes. Population, 20,492.

AVEMPACE. ABU BEKR MOHAMMED IBN JAHYA, surnamed Ibn Badja or Ibn Sayeg (*i.e.*, son of the goldsmith), whose name has been corrupted by the Latins into Avempace, Avenpace, or Aben Pace, was the earliest and one of the most distinguished of the Arab philosophers in Spain. Almost nothing is known of the events in his life; he was born, probably at Saragossa, towards the close of the 11th century, and died at Fez in 1138 at a not very advanced age. Like most of the Arab philosophers, he was a physician by profession, and he is also said to have been a man of wide general culture. He was a skilled musician, mathematician, astronomer, and poet, and though he is now known only through his metaphysical speculations, these do not seem to have been his favourite studies. His writings, if we accept the report of Occibia, were varied and numerous. Several treatises on logical subjects are mentioned by Casiri as still among the MSS. at the Escurial, and some smaller pieces are also found in other

libraries. The most important of his works is that noticed by Averroes, who promised a complete discussion of it, but unfortunately neither the treatise nor the exposition has come down to us. Our knowledge of it is almost entirely drawn from the notices given by Moses of Narbonne, a Jewish writer of the 14th century, in his commentary on the somewhat similar work of Ibn Tofail. The title of the work may be translated as the *Régime* or *Conduct of the Solitary*, understanding by that the organised system of rules, by obedience to which the individual may rise from the mere life of the senses to the perception of pure intelligible principles, and may participate in the divine thought which sustains the world. These rules for the individual are but the image or reflex of the political organisation of the perfect or ideal state; and the man who strives to lead this life is called the *solitary*, not because he withdraws from society, but because, while in it, he remains a stranger to its ways, and guides himself by reference to a higher state, an ideal society. Avempace does not develop at any length this curious Platonic idea of the perfect state. His object is to discover the highest end of human life, and with this view he classifies the various activities of the human soul, rejects such as are material or animal, and then analyses the various spiritual forms to which the activities may be directed. He points out the graduated scale of such forms, through which the soul may rise, and shows that none are final or complete in themselves, except the pure intelligible forms, the ideas of ideas. These the intellect can grasp, and in so doing it becomes what he calls *intellectus acquisitus*, and is in a measure divine. This self-consciousness of pure reason is the highest object of human activity, and is to be attained by the speculative method. The intellect has in itself power to know ultimate truth and intelligence, and does not require a mystical illumination as Algazali taught. Avempace's principles, it is clear, lead directly to the Averroistic doctrine of the unity of intellect, but the obscurity and incompleteness of the *Régime* do not permit us to judge how far he anticipated the later thinker. (See Munk, *Mélanges de Phil. Juive et Arabe*, pp. 383-410.)

AVENBRUGGER, or AUENBRUGGER, LEOPOLD, a physician of Vienna, the discoverer of the important mode of investigating diseases of the chest and abdomen by *auscultation*. His method was to apply the ear to the chest, and to note the sounds it afforded on percussion by the hand, or what is called *immediate auscultation*. His Latin treatise, *Inventum novum ex Percussione Thoracis Humani Interni Pectoris Morbos detegendi*, published in 1761, excited little attention, until it was translated and illustrated by Corvisart, in 1808, when it soon led the way to Laennec's great improvement of aiding the ear by the stethoscope, or *mediate auscultation*. The great value of the method introduced by Avenbrugger, in the diagnosis of internal diseases, is now universally acknowledged. He was born at Grätz in 1722, and died in 1809.

AVENTINUS [JOHANN THURMAYR], author of the *Annals of Bavaria*, was born in the year 1466 at Abensberg. He studied first at Ingoldstadt, and afterwards in the university of Paris. In 1503 he privately taught rhetoric and poetry at Vienna, and in 1507 he publicly taught Greek at Cracow, in Poland. In 1509 he read lectures on some of Cicero's works at Ingoldstadt, and in 1512 was appointed preceptor to Prince Ludwig and Prince Ernst, sons of Albert the Wise, duke of Bavaria, and travelled with the latter of these princes. After spending several years in the collection of materials he undertook to write the *Annales Boiorum*, or *Annals of Bavaria*, being encouraged by the dukes of that territory, who settled a pension upon him, and gave him hopes that they would defray the expenses of publication. He finished, but did not publish, his work in 1528, and in the following year he was imprisoned on suspicion of heresy. He was soon released from confinement, but the indignity he had suffered seriously affected him. He died in 1534 at Ratisbon. His history, which has gained for him considerable reputation as a writer, was published, but with some important omissions, in 1554, by Ziegler, professor of poetry in the university of Ingoldstadt. These passages, which were adverse to the Roman Catholics, were all restored in the edition published at Basle in 1580, by Nicholas Cisner. Besides his other writings, Gesner attributes to him a curious work, entitled *Numerandi per digitos manusque Veterum Consuetudines*.

AVENZOAR [ABU MERWAN ABDALMALEC IBN ZOHR], an eminent Arabian physician, who flourished about the end of the 11th or beginning of the 12th century, was born at Seville, where he exercised his profession with great reputation. His ancestors had been celebrated as physicians for several generations, and his son was afterwards held by the Arabians to be even more eminent in his profession than Avenzoar himself. He was contemporary with Averroes, who, according to Leo Africanus, heard his lectures and learned physic of him. This seems probable, because Averroes more than once gives Avenzoar very high and partly deserved praise, calling him admirable, glorious, the treasure of all knowledge, and the most supreme in physic from the time of Galen to his own. Avenzoar, notwithstanding, is by the generality of writers reckoned an empiric; but Dr Freind observes that this character suits him less than any other of the Arabian physicians. Avenzoar belonged, in many respects, to the *Dogmatists* or *Rational School*, rather than to the *Empirics*. He was a great admirer of Galen; and in his writings he protests emphatically against quackery and the superstitious remedies of the astrologers. He shows no inconsiderable knowledge of anatomy in his remarkable description of inflammation and abscess of the mediastinum in his own person, and its diagnosis from common pleuritis as well as from abscess and dropsy of the pericardium. In cases of obstruction or of palsy of the gullet, his three modes of treatment are ingenious. He proposes to support the strength by placing the patient in a tepid bath of nutritious liquids, that might enter by cutaneous imbibition, but does not recommend this. He speaks more favourably of the introduction of food into the stomach by a silver tube; and he strongly recommends the use of nutritive enemata. From his writings it would appear that the offices of physician, surgeon, and apothecary were already considered as distinct professions. He wrote a book entitled *The Method of Preparing Medicines and Diet*, which was translated into Hebrew in the year 1280, and thence into Latin by Paravicius, whose version, first printed at Venice 1490, has passed through several editions.

AVERAGE, a term used in maritime commerce to signify damages or expenses resulting from the accidents of navigation. Average is either *general* or *particular*. General average arises when sacrifices have been made, or expenditures incurred, for the preservation of the ship, cargo, and freight, from some peril of the sea, or from its effects. It implies a subsequent contribution, from all the parties concerned, rateably to the values of their respective interests, to make good the loss thus occasioned. Particular average signifies the damage or partial loss happening to the ship, goods, or freight by some fortuitous or unavoidable accident. It is borne by the parties to whose property the misfortune happens, or by their insurers. The term average originally meant what is now distinguished as general average; and the expression "particular average," although not strictly accurate, came to be afterwards used for the convenience of distinguishing those damages or partial

losses for which no general contribution could be claimed.

Although nothing can be more simple than the fundamental principle of general average, that a loss incurred for the advantage of all the coadventurers should be made good by them all in equitable proportion to their stakes in the adventure, the application of this principle to the varied and complicated cases which occur in the course of maritime commerce has given rise to many diversities of usage at different periods and in different countries. It is soon discovered that the principle cannot be applied in any settled or consistent manner unless by the aid of rules of a technical and sometimes of a seemingly arbitrary character. The distinctions on which these rules turn are often very refined indeed. This is the chief reason why no real progress has yet been made towards an international system of general average, notwithstanding repeated conferences and other efforts by most competent representatives from different countries, seeking to arrive at a common understanding as a preliminary basis for such a system. A brief summary only can be given here of the rules which have been established in Great Britain by usage, or by legal decisions, in connection with the subject.

All general average losses may be divided into two principal classes—(1), *sacrifices* of part of the cargo and freight, or of part of the ship, for the general safety; (2), *extraordinary expenditures* incurred with the same object. We shall notice these in their order.

When a part of a *cargo* is thrown overboard (or *jettisoned*, as it is termed) to save the ship from foundering in a storm, or to float her when stranded, or to facilitate her escape from an enemy, the loss of the goods and of the freight attached to them must be made good by average contribution. But if goods jettisoned have been originally stowed on deck, no contribution can be demanded for them, unless they are so carried according to the common usage and course of trade on the voyage for which they are shipped, or with the consent of all the parties concerned in the ship and cargo.

If, instead of being thrown overboard, the goods are put into boats or lighters, and lost or damaged before reaching the shore, such loss is regarded as a virtual jettison, and gives a claim to average contribution. The same rule applies to damage occasioned by the goods being put ashore on muddy ground, or where they cannot be kept in ordinary safety. But when the goods have been conveyed to a place of ordinary safety, they cease to be at the risk of the general interest; and should they be damaged there by fire or other accidents the loss must be borne by the individual proprietors, or by their insurers.

Damage done to the cargo by discharging it at a port of refuge in the manner and under the circumstances customary at that port, is not allowed as general average. This rule covers the case of wastage, breakage, leakage, &c., from handling the goods in the ordinary course of discharging, warehousing, and reshipping.

If goods are thrown overboard from having become, through heating or other cause peculiar to their own condition, a source of special danger to the whole interest, the loss is not recoverable in general average. So, too, if a cargo is discharged at a port of refuge from damage resulting from its own *vice propre*, the costs are chargeable to its owners.

The loss of corn, salt, guano, or similar goods, arising from their being pumped up or baled out with the water in the vessel, is not recoverable by average contribution. The damage done to the cargo by means of water thrown down the hatches, or admitted into the ship by scuttling her, for the purpose of extinguishing an accidental fire, was excluded from general average by the usage of Lloyds up till 1873. In that year the courts of Queen's Bench and Exchequer Chamber expressed a strong opinion in connection with the case of Stewart *v.* the West India and Pacific Steamship Company, that such damage ought to be made good by average contribution. The usage has now been altered accordingly.

The amount of compensation to be made for goods sacrificed by general average acts is determined by the net market price they would have produced on arrival at the port of destination had they not been sacrificed; but under deduction of the freight attaching to them (which is made good to the shipowners), and of the charges for duties and landing expenses which are saved.

The general average acts next to be considered are those which involve sacrifices of part of the *ship or her materials.*

The same principles which regulate the case of goods thrown overboard apply also to the jettison of the ship's chains, anchors, hawsers, spars, boats, or other stores. But if water-casks are stowed on deck, or if chains and hawsers are carried on deck when the vessel is not near the land so as to render it necessary that they should be so carried, the loss arising from the jettison of these articles falls on the shipowner; and if boats are jettisoned in consequence of their having been broken adrift from their fastenings on deck by the force of the sea, they are excluded from general average, and are charged to particular average on the ship. The damage done to the ship by cutting holes to effect a jettison of the cargo, or to pour down water to a fire, or by scuttling her for that purpose, is allowed as a general average charge. The damage arising from cutting or knocking away a portion of the ship's bulwarks in order to prevent the deck from being flooded in a storm, is compensated in the same manner.

When sails or masts are cut away in order to right a ship which has been thrown on her beam-ends, or to prevent her from driving on a lee-shore, the loss is made good by average contribution; but if the object in cutting away a sail or spar be merely to *save a mast*, the loss is not made good in general average.

It frequently happens that masts or yards are sprung and carried away by the force of the wind, and are left entangled in the rigging, or hanging over the ship's side in what is termed "a state of wreck;" in these circumstances it becomes necessary to cut them away, with the sails and rigging attached, and to throw the whole overboard, otherwise they would impede the navigation, and endanger the ship and cargo. On this ground it is held by some authorities that the loss caused by the act of cutting them away should be made good by average contribution. But this act is the direct consequence of the previous accident, which places these articles in a situation where it is impossible to save them without imperilling the ship, cargo, and lives. It would not be reasonable to imperil these for such a purpose; whence it follows that the displaced articles are already *virtually* lost by means of the original accident, before the loss is *actually* consummated by cutting them away. This loss is accordingly excluded, by the usage of this country, from average contribution. On the same principle, no contribution can be demanded for any articles which are sacrificed as having themselves become, through previous accident, the immediate cause of danger to the whole interest.

The loss of sails or spars, in consequence of carrying a press of canvas to avoid a lee-shore, or to escape from an enemy, is not the subject of general average in this country; neither is the damage suffered by the ship from *straining*, under any such extraordinary press of sail.

When anchors and cables are slipped from in order to work a vessel off a lee-shore, or to avoid collision with another ship, the loss is made good by average contribution; but if the cable is slipped in order that the vessel may join convoy, or because the anchor has become

hooked to some object at the bottom and cannot be raised, the loss is borne by the shipowner.

When sails, ropes, or other materials are cut up and used at sea for the purpose of stopping leaks or to rig jury-masts, or when the common benefit requires that they should be applied to some purpose for which they were not originally intended, the loss is made good in general average. The same rule applies to the case of hawsers, cables, anchors, sails, or boats, lost or damaged in attempting to force off a stranded vessel from the shore.

The damage sustained in defending a ship against a pirate or an enemy is not the subject of general average in this country; it is treated as particular average on the ship.

It has been much debated by writers on maritime law, whether the voluntary stranding of a ship, in order to prevent her from foundering, should be treated as a general or as a particular average loss. In the United States it has been settled, by judicial decision, that the loss in question constitutes a general average claim; but the opposite doctrine is acted upon in the usage of Great Britain, and the point has never been decided by the courts of law. It appears to us that the argument greatly preponderates against the rule adopted in the United States, and in favour of the usage established in this country. The only reason for regarding this loss as the subject of general average is, that it originates in the intentional act of running the ship aground, for the preservation, as far as possible, of the whole interest concerned. But it can seldom be known beforehand how the different interests at stake will be specially affected by the act in question;—whether, for instance, the damage to the cargo may not be more serious than the damage to the ship, or *vice versa.* Thus no particular part of the interest can be said to be intentionally sacrificed for the benefit of the whole; the intention, indeed, is not to sacrifice any one part, but to place the whole interest in a situation of less peril than it would otherwise have been in. What particular damages may thereafter ensue to either ship or cargo will depend, in each case, on a variety of circumstances entirely accidental in their character, and therefore in no proper sense the subject of previous intention. The same rule, therefore, which excludes from general average accidental damages in all other cases, ought to exclude them in this case also. Moreover, when the alternatives are either that the vessel be left to founder, or that she be run ashore with a chance of preservation, there can really be no room for choice, or, at all events, the elements of will and intention are entirely subordinate in the part they must play under the pressure of the existing circumstances; and in this view the stranding is as truly inevitable as if it had been caused by the force of the winds and waves alone.

But, even were these reasons less weighty than it appears they are, a serious practical objection might be urged against the doctrine that voluntary stranding should be a general average loss, on the ground that it would in most cases be impossible to distinguish between the damages received by the ship and cargo prior to the stranding, and those sustained after or in consequence of it. It is needless to remark, that before a ship can be in such imminent danger of foundering as to render it necessary to run her ashore, she must be presumed to have sustained a very considerable amount of damage; and the probability is, that the cargo also will have suffered to a corresponding extent. Up to this point these damages are confessedly *particular* average; and were it held that the damages *after* the stranding were the subject of *general* average, it would, of course, be necessary to distinguish the separate damages that belonged to each. But in every case these different damages would exist in varying proportions, yet always so incorporated together that justice could never have a more perplexing task than that of discriminating between them. No general rule could be applied that would meet the widely different circumstances of each particular case; and the arbitrary method of adjustment that would alone be possible would doubtless give rise to endless dissatisfaction and dispute. On the ground of expediency, therefore, as well as on that of principle, the usage now established in this country ought to be maintained, notwithstanding the high authorities by whom the opposite practice has been countenanced.

The amount of general average losses on the ship is compensated by allowing to the owners the cost of repairs, or of new materials in place of those sacrificed, subject to the deduction of one-third for the difference of value between old and new; but no deduction is made from the cost of new anchors, and only one-sixth is deducted from the cost of new chain cables. If the ship be on her first voyage (which is held to include the homeward as well as the outward passage), the repairs and new materials are allowed in full.

We now proceed to notice the second principal class of general average losses, consisting of extraordinary expenditures incurred with a view to the common benefit.

When a ship is obliged to put into a port of refuge, in consequence of damage received in the course of the voyage, the usage in this country is to allow as general average all the charges connected with the entrance of the vessel into the port, and with the landing and warehousing of the cargo, when this is necessary to admit of the ship being repaired. Thus the expenses of pilotage or other assistance into the port, the harbour dues, and similar charges, the costs of the protest taken by the master and crew, and of the survey held to ascertain whether the cargo requires to be discharged, together with the charges for landing the cargo and conveying it to a warehouse or other place of safety, are all made good as general average. The costs of repairing the ship are charged to general average only in so far as the repairs may refer to damages which are themselves the proper subject of general contribution. If the damages are of the nature of particular average, as is more usually the case, they are charged accordingly; or if they proceed from "wear and tear," they are stated against the shipowner.

The warehouse rent for the cargo at a port of refuge, and any expenses connected with its preservation, form special charges against that particular interest, and are borne by the proprietors of the goods, or by their insurers. When goods are insured "free from particular average, unless the ship be stranded," it is necessary, if the ship has not been stranded, to distinguish the charges for warehouse rent and fire insurance from those incurred in connection with the preservation of the goods from the effects of damage,—the underwriters being liable for the former, but not for the latter.

The expenses of reshipping the cargo, and the pilotage, or other charges *outwards*, are borne by the freight. If the entire cargo cannot be taken on board again, from the want, at the port of refuge, of the usual facilities for stowing it, the loss or expenses resulting from the exclusion of part of it are not treated, in this country, as the subject of general contribution.

The wages and provisions of the master and crew during the period of detention at a port of refuge are not admitted as a charge against general average, it being held that the shipowner is bound to keep a competent crew on board the ship from the commencement to the end of the voyage at his own expense.

The charges for agency at a port of refuge are brought against the general average, even though they may have been originally made in the form of separate charges

against the ship and cargo respectively. Commissions on money advanced, maritime interest on bottomry and *respondentia*, and the loss on exchanges, &c., are apportioned relatively to the gross sums expended on behalf of the several interests concerned.

The expenses incurred in getting a stranded ship off the ground, the hire of extra hands to pump a ship which has sprung a leak, and the sums awarded for salvage or for other services rendered to the ship and cargo under any extraordinary emergencies, are compensated by average contribution. But this rule applies only to the *extraneous* assistance that may have been obtained, the crew being bound to do their utmost in the service of the ship on all occasions, with extra remuneration for what they might consider extraordinary exertions on their part.

The costs of reclaiming the ship and cargo after having been captured are allowed as general average charges; and although *ransom* to an enemy is prohibited in this country by legal enactment, it seems that this does not apply to the case of money or goods given up by way of composition to pirates for the liberation of the ship and cargo, and that this would also form a subject of average contribution.

When the ship and cargo arrive at the port of destination it is unnecessary, in ordinary cases, to distinguish, in the adjustment of the general average, between the losses which have arisen from *sacrifices* and those which have resulted from *expenditures* for the common benefit. But if the ship and cargo should be lost before reaching their destination, no contribution is due for the goods or ship's materials which may have been *sacrificed* at a former stage of the voyage, the owners of these being in no worse position than any of their coadventurers. On the other hand, it is evident that when money has been *expended* for the common benefit, the subsequent loss of the ship and cargo should not affect the right of the party who has made the advance to recover it in full from all the parties for whose advantage it was originally made. Hence, while *sacrifices* are made good only in the event of the ship and cargo being ultimately saved, *expenditures* must be reimbursed whether the ship and cargo be eventually saved or lost; and the contribution for these expenditures must be regulated by the values of the ship, cargo, and freight as they stood at the time when the advances were made.

If, however, the money required for average expenditures has been raised by means of bottomry, and the ship be lost before completing the voyage, there can be no claim for reimbursement,—the risk being assumed by the bottomry lender in consideration of the premium he receives on the sum advanced. When there is no bottomry, it is a usual practice, but not an invariable rule, to insure the average disbursements by a special policy. When this has been done, and when the amount has been recovered on the subsequent loss of the ship, it cannot be again claimed from the individuals who would otherwise have been liable. But if the expenditures are not insured, either by a bottomry contract, or by a special policy, and if the ship and cargo be totally lost in the subsequent course of the voyage, the parties for whose benefit the expenditures were incurred must reimburse them on the principles already explained. These parties, however, have recourse on their original insurers, not only for the total loss of the interests insured, but also for the previous expenditures, although the insurers may thus be called on to pay a *larger sum* than the amount of the insurance.

The contribution for general average losses is regulated by the values of the respective interests for the benefit of which they were incurred. The practical rule adopted, in all ordinary cases, is to estimate the ship, cargo, and freight at their *net* values to their owners, in the state in which they arrive at the port of destination, ***but including in these values the sums made good for sacrifices***, and to assess the contribution accordingly. The necessity for including the amount of compensation made for sacrifices in the valuations on which the contribution is charged, arises from the principle that all the parties interested in the adventure should bear the ultimate loss in exact proportion to their respective interests, which would not be the case if the owners of the articles sacrificed were to recover their full value without being themselves assessed for the loss thereon in the same manner as their coadventurers.

The contributory value of the *ship* is accordingly her actual value to her owner in the state in which she arrives, whether damaged or otherwise, including the sum made good in the general average for any sacrifices which may have been made of part of the ship or her materials.

The value of the *cargo* for contribution is its net market value on arrival, after deducting the charges incurred for freight, duty, and landing expenses, but without deducting the costs of insurance or commission. If goods be damaged, they contribute only according to their deteriorated value; and if special charges have been incurred on the cargo at a port of refuge (as for warehouse rent, &c.), the amount of these charges is deducted. The sum charged to general average for goods sacrificed is of course added to the valuation. All goods carried in the ship for the purposes of traffic must be included in the valuation of the cargo; but the wearing apparel, or personal effects, of the passengers and crew are exempted from contribution.

The value of the *freight* for contribution is the sum received by the shipowner on the completion of the voyage for the carriage of the cargo, after deducting from that sum the wages reckoned as from the date of the casualty, the port charges at the place of destination, and the special charges against the freight which may have been incurred at a port of refuge, consisting of the costs of reshipping the cargo, and of outward pilotage, &c. The provisions for the voyage are not deducted, as these are held to have formed part of the original value of the *ship*. If the freight has been paid in advance, it forms part of the value of the *goods*, and, consequently, does not contribute as a separate interest. When a sum has been advanced on account of freight, subject to insurance, it must be distinguished from the portion of the freight which remains at the shipowner's risk, and be charged separately for its rateable contribution; and the freight so advanced is not subject to deduction for wages, &c., this deduction being made only from the freight at risk. It has been decided that, when a vessel has been originally chartered for a double voyage, the whole freight to be earned under the charter-party must contribute at its net value, after deducting the wages and other charges which must be incurred in earning it. The effect of this rule is to render the freight attaching to the *return* voyage, as well as that attaching to the voyage *outwards*, liable to contribute for average losses arising in the course of the outward passage,—a result the equity of which is not always very apparent.

An adjustment of general average made at any foreign port where the voyage may terminate, if proved to be in conformity with the law and usage of the country to which such foreign port belongs, is binding on all the parties interested as coadventurers, although they may be subjects of this country, and although the adjustment may be made on principles different from those sanctioned by the laws or usages of Britain. The reason for this rule is, that the parties engaging in the adventure are held to assent to the known maritime usage according to which general average is adjusted on the arrival of the ship and goods at the port of destination.

The subject of general average is only incidentally connected with that of marine insurance, being itself a distinct branch of maritime law. But the subject of particular average arises directly out of the contract of insurance, and will therefore be best considered in connection with it. (See INSURANCE.)

For further information with respect to the subject of average, the reader is referred to the famous work of M. Valin, *Commentaire sur l'Ordonnance de* 1681, t. ii. p. 147–198, ed. 1760; to Emerigon, *Traité des Assurances*, t. i. pp. 598–674; Arnould on *Marine Insurance*; and the treatises on *Average* of Stevens, Benecke, Baily, Hopkins, and Lowndes. (J. WA.)

AVERNUS, a lake of Campania in Italy, near Baiæ, occupying the crater of an extinct volcano, and about a mile and a half in circumference. From the gloomy horror of its surroundings, and the mephitic character of its exhalations, it was regarded by ancient superstition as an entrance to the infernal regions. It was especially dedicated to Proserpine, and an oracle was maintained on the spot. In 214 B.C., Hannibal with his army visited the shrine, but not so much, according to Pliny, for purposes of piety, as in hope of surprising the garrison of Puteoli. By some critics the Cimmerians of Homer were supposed to have been the inhabitants of this locality, and Virgil in his *Æneid* adopted the popular opinions in regard to it. Originally there seems to have been no outlet to the lake, but Agrippa opened a passage to the Lucrine, and turned this "mouth of hell" into a harbour for ships. The channel, however, appears to have become obstructed at a later period. In the reign of Nero it was proposed to construct a ship-canal from the Tiber through Avernus to the Gulf of Baiæ, but the works were hardly commenced. The plan of connecting the lake with the Gulf of Baiæ was brought forward as late as 1858, but only to be abandoned. The *Lago d'Averno* is now greatly frequented by foreign tourists, who are shown what pass for the Sibyl's Grotto, the Sibyl's Bath, and the entrance to the infernal regions, as well as the tunnel from Cumæ, and ruins variously identified as belonging to a temple or a bathing-place.

AVERROES, known among his own people as Abûl-Walid Mohammed Ibn-Ahmed Ibn-Mohammed IBN-ROSHD, the kâdi, was born at Cordova in 1126, and died at Marocco in 1198. His early life was occupied in mastering the curriculum of theology, jurisprudence, mathematics, medicine, and philosophy, under the approved teachers of the time. The years of his prime were a disastrous era for Mahometan Spain, where almost every city had its own petty king, whilst the Christian princes swept the land in constant inroads. But with the advent of the Almohades, the enthusiasm which the desert tribes had awakened, whilst it revived religious life and intensified the observance of the holy law within the realm, served at the same time to reunite the forces of Andalusia, and inflicted decisive defeats on the chiefs of the Christian North. For the last time before its final extinction the Moslem caliphate in Spain displayed a splendour which seemed to rival the ancient glories of the Ommiade court. Great mosques arose; schools and colleges were founded; hospitals, and other useful and beneficent constructions, proceeded from the public zeal of the sovereign; and under the patronage of two liberal rulers, Jusuf and Jakûb, science and philosophy flourished apace. It was Ibn-Tofail (Abubacer), the philosophic vizier of Jusuf, who introduced Averroes to that prince, and Avenzoar (Ibn-Zohr), the greatest of Moslem physicians, was his friend. Averroes, who was versed in the Malekite system of law, was made kâdi of Seville (1169), and in similar appointments the next twenty-five years of his life were passed. We find him at different periods in Seville, Cordova, and Marocco, probably following the court of Jusuf Almansur, who took pleasure in engaging him in discussions on the theories of philosophy and their bearings on the faith of Islam. But science and free thought then, as now, in Islam, depended almost solely on the tastes of the wealthy and the favour of the monarch. The ignorant fanaticism of the multitude viewed speculative studies with deep dislike and distrust, and deemed any one a Zendik (infidel) who did not rest content with the natural science of the Koran. These smouldering hatreds burst into open flame about the year 1195. Whether, as one story ran, he had failed in conversation and in his writings to pay the customary deference to the emir, or a court intrigue had changed the policy of the moment, at any rate Averroes was accused of heretical opinions and pursuits, stripped of his honours, and banished to a place near Cordova, where his actions were closely watched. Tales have been told of the insults he had to suffer from a bigoted populace. At the same time efforts were made to stamp out all liberal culture in Andalusia, so far as it went beyond the little medicine, arithmetic, and astronomy required for practical life. But the storm soon passed, when the transient passion of the people had been satisfied, and Averroes for a brief period survived his restoration to honour. He died in the year before his patron Almansur, with whom (in 1199) the political power of the Moslems came to an end, as did the culture of liberal science with Averroes. The philosopher left several sons, some of whom became jurists like Averroes's grandfather. One of them has left an essay, expounding his father's theory of the intellect. The personal character of Averroes is known to us only in a general way, and as we can gather it from his writings. His clear, exhaustive, and dignified style of treatment evidences the rectitude and nobility of the man. In the histories of his own nation he has little place; the renown which spread in his lifetime to the East ceased with his death, and he left no school. Yet, from a note in a manuscript, we know that he had intelligent readers in Spain more than a century afterwards. His historic fame came from the Christian Schoolmen, whom he almost initiated into the system of Aristotle, and who, but vaguely discerning the expositors who preceded, admired in his commentaries the accumulated results of two centuries of labours.

For Aristotle the reverence of Averroes was unbounded, and to expound him was his chosen task. The uncritical receptivity of his age, the defects of the Arabic versions, the emphatic theism of his creed, and the rationalising mysticism of some Oriental thought, may have sometimes led him astray, and given prominence to the less obvious features of Aristotelianism. But in his conception of the relation between philosophy and religion, Averroes had a light which the Latins were without. The science, falsely so called, of the several theological schools, their groundless distinctions and sophistical demonstrations, he regarded as the great source of heresy and scepticism. The allegorical interpretations and metaphysics which had been imported into religion had taken men's minds away from the plain sense of the Koran, and destroyed the force of those appeals which had been spoken to the hearts and understandings of our common humanity, not to the wisdom of the "people of demonstration." God had declared a truth meet for all men, which needed no intellectual superiority to understand, in a tongue which each human soul could apprehend according to its powers and feelings. Accordingly, the expositors of religious metaphysics, Algazali included, are the enemies of true religion, because they make it a mere matter of syllogism. Averroes maintains that a return must be made to the words and teaching of the prophet; that science must not expend itself in dogmatising on the metaphysical consequences of fragments of doctrine for

popular acceptance, but must proceed to reflect upon and examine the existing things of the world. Averroes, at the same time, condemns the attempts of those who tried to give demonstrative science where the mind was not capable of more than rhetoric: they harm religion by their mere negations, destroying an old sensuous creed, but cannot build up a higher and intellectual faith.

In this spirit Averroes does not allow the fancied needs of theological reasoning to interfere with his study of Aristotle, whom he simply interprets as a truth-seeker. The points by which he told on Europe were all implicit in Aristotle, but Averroes set in relief what the original had left obscure, and emphasised things which the Christian theologian passed by or misconceived. Thus Averroes had a double effect. He was the great interpreter of Aristotle to the later Schoolmen, worthy of a place, according to Dante, beside the glorious sages of the heathen world. On the other hand, he came to represent those aspects of Peripateticism most alien to the spirit of Christendom; and the deeply-religious Moslem gave his name to the anti-sacerdotal party, to the materialists, sceptics, and atheists, who defied or undermined the dominant beliefs of the church.

On three points Averroes, like other Moslem thinkers, came specially into relation, real or supposed, with the religious creed, viz., the creation of the world, the divine knowledge of particular things, and the future of the human soul. But the collision was rather with the laboured ratiocinations by which the Asharite and Motazelite theologians aimed at rationalising dogma than with the doctrine of religion in its simplicity. True philosophy is the foster sister of religion, but is the critic of scholastic subtleties. In regard to the second charge, Averroes himself remarks that philosophy only protests against reducing the divine to the level of the created mind. But the real grandeur of Averroes is seen in his resolute prosecution of the stand-point of science in matters of this world, and in his recognition that religion is not a branch of knowledge to be reduced to propositions and systems of dogma, but a personal and inward power, an individual truth which stands distinct from, but not contradictory to, the universalities of scientific law. In his science he followed the Greeks, and to the Schoolmen he and his compatriots rightly seemed philosophers of the ancient world. He maintained alike the claim of demonstrative science with its generalities for the few who could live in that ethereal world, and the claim of religion for all,—the common life of each soul as an individual and personal consciousness. But theology, or the mixture of the two, he regarded as a source of evil to both—fostering the vain belief in a hostility of philosophers to religion, and meanwhile corrupting religion by a pseudo-science. A stand-point like this was the very antithesis of scholasticism; it was the anticipation of an adequate view which modern speculation has seldom exhibited.

The latent nominalism of Aristotle only came gradually to be emphasised through the prominence which Christianity gave to the individual life, and, apart from passing notices as in Abelard, first found clear enunciation in the school of Duns Scotus. The Arabians, on the contrary, emphasised the idealist aspect which had been adopted and promoted by the Neo-Platonist commentators. Hence, to Averroes the eternity of the world finds its true expression in the eternity of God. The ceaseless movement of growth and change, which presents matter in form after form as a continual search after a finality which in time and movement is not, and cannot be reached, represents only the aspect the world shows to the physicist and to the senses. In the eye of reason the full fruition of this desired finality is already and always attained; the actualisation, invisible to the senses, is achieved now and ever, and is thus beyond the element of time. This transcendent or abstract being *is* that which the world of nature is always *seeking*. He is thought or intellect, the actuality, of which movement is but the fragmentary attainment in successive instants of time. Such a mind is not in the theological sense a creator, yet the onward movement is not the same as what some modern thinkers seem to mean by development. For the perfect and absolute, the consummation of movement is not generated at any point in the process; it is an ideal end, which guides the operations of nature, and does not wait upon them for its achievement. God is the unchanging essence of the movement, and therefore its eternal cause.

A special application of this relation between the prior perfect, and the imperfect, which it influences, is found in the doctrine of the connection of the abstract (transcendent) intellect with man. This transcendent mind is sometimes connected with the moon, according to the theory of Aristotle, who assigned an imperishable matter to the sphere beyond the sublunary, and in general looked upon the celestial orbs as living and intelligent. Such an intellect, named active or productive, as being the author of the development of reason in man, is the permanent, eternal thought, which is the truth of the cosmic and physical movement. It is in man that the physical or sensible passes most evidently into the metaphysical and rational. Humanity is the chosen vessel in which the light of the intellect is revealed; and so long as mankind lasts there must always be some individuals destined to receive this light. "There must of necessity always be some philosopher in the race of man." What seems from the material point of view to be the acquisition of learning, study, and a moral life, is from the higher point of view the manifestation of the transcendent intellect in the individual. The preparation of the heart and faculties gives rise to a series of grades between the original predisposition and the full acquisition of actual intellect. These grades in the main resemble those given by Avicenna. But beyond these, Averroes claims as the highest bliss of the soul a union in this life with the actual intellect. The intellect, therefore, is one and continuous in all individuals, who differ only in the degree which their illumination has attained. Such was the Averroist doctrine of the unity of intellect—the eternal and universal nature of true intellectual life. By his interpreters it was transformed into a theory of one soul common to all mankind, and when thus corrupted conflicted not unreasonably with the doctrines of a future life, common to Islam and Christendom.

Averroes, rejected by his Moslem countrymen, found a hearing among the Jews, to whom Maimonides had shown the free paths of Greek speculation. In the cities of Languedoc and Provence, to which they had been driven by Spanish fanaticism, the Jews no longer used the learned Arabic, and translations of the works of Averroes became necessary. His writings became the text-book of Levi ben Gerson at Perpignan, and of Moses of Narbonne. Meanwhile, before 1250, Averroes became accessible to the Latin Schoolmen by means of versions, accredited by the names of Michael Scot and others. William of Auvergne is the first Schoolman who criticises the doctrines of Averroes, not, however, by name. Albertus Magnus and St Thomas devote special treatises to an examination of the Averroist theory of the unity of intellect, which they labour to confute in order to establish the orthodoxy of Aristotle. But as early as Ægidius Romanus (1247–1316), Averroes had been stamped as the patron of indifference to theological dogmas, and credited with the emancipation which was equally due to wider experience and the lessons of the Crusades. There had never been an absence of protest

against the hierarchical doctrine. Berengar had struggled in that interest, and with Abelard, in the 12th century, the revolt against authority in belief grew loud. The dialogue between a Christian, a Jew, and a philosopher suggested a comparative estimate of religions, and placed the natural religion of the moral law above all positive revelations. Nihilists and naturalists, who deified logic and science at the expense of faith, were not unknown at Paris in the days of John of Salisbury. In such a critical generation the words of Averroism found willing ears, and pupils who outran their teacher. Paris became the centre of a sceptical society, which the decrees of bishops and councils, and the enthusiasm of the orthodox doctors and knight-errants of Catholicism, were powerless to extinguish. At Oxford Averroes told more as the great commentator. In the days of Roger Bacon he had become an authority. Bacon, placing him beside Aristotle and Avicenna, recommends the study of Arabic as the only way of getting the knowledge which bad versions made almost hopeless; and the student of the present day might echo his remark. In Duns Scotus, Averroes and Aristotle are the unequalled masters of the science of proof; and he pronounces distinctly the separation between Catholic and philosophical truth, which became the watchword of Averroism. By the 14th century Averroism was the common leaven of philosophy; John Baconthorpe is the chief of Averroists, and Walter Burley has similar tendencies.

Meanwhile Averroism had, in the eye of the great Dominican school, come to be regarded as the arch-enemy of the truth. When Frederick II. consulted a Moslem free-thinker on the mysteries of the faith, when the phrase or legend of the "Three Impostors" presented in its most offensive form the scientific survey of the three laws of Moses, Christ, and Mahomet, and when the characteristic doctrines of Averroes were misunderstood, it soon followed that his name became the badge of the scoffer and the sceptic. What had begun with the subtle disputes of the universities of Paris, went on to the materialist teachers in the medical schools and the sceptical men of the world in the cities of Northern Italy. The patricians of Venice and the lecturers of Padua made Averroism synonymous with doubt and criticism in theology, and with sarcasm against the hierarchy. Petrarch, vexed by the arrogance and over-refinements of their argumentation, and by the barbarism of their words, refuses to believe that any good thing can come out of Arabia, and speaks of Averroes as a mad dog barking against the church. In works of contemporary art Averroes is at one time the comrade of Mahomet and Antichrist; at another he lies with Arius and Sabellius, vanquished by the lance of St Thomas.

It was in the universities of North Italy that Averroism finally settled, and there for three centuries it continued as a stronghold of Scholasticism to resist the efforts of revived antiquity and of advancing science. Padua became the seat of Averroist Aristotelianism; and, when Padua was conquered by Venice in 1405, the printers of the republic spread abroad the teaching of the professors in the university. As early as 1300, at Padua, Petrus Aponensis, a notable expositor of medical theories, had betrayed a heterodoxy in faith; and John of Jandun, one of the pamphleteers on the side of Lewis of Bavaria, was a keen follower of Averroes, whom he styles a "perfect and most glorious physicist." Urbanus of Bologna, Paul of Venice (d. 1428), and Cajetanus de Thienis (1387–1465), established by their lectures and their discussions the authority of Averroes; and a long list of manuscripts rests in the libraries of Lombardy to witness the diligence of these writers and their successors. Even a lady of Venice, Cassandra Fedele, in 1480, gained her laurels in defence of Averroist theses.

With Pomponatius, in 1495, a brilliant epoch began for the school of Padua. Questions of permanent and present interest took the place of outworn scholastic problems. The disputants ranged themselves under the rival commentators, Alexander and Averroes; and the immortality of the soul became the battle-ground of the two parties. Pomponatius defended the Alexandrist doctrine of the utter mortality of the soul, whilst Augustinus Niphus, the Averroist, was entrusted by Leo X. with the task of defending the Catholic doctrine. The parties seemed to have changed when Averroism thus took the side of the church; but the change was probably due to compulsion. Niphus had edited the works of Averroes (1495–7); but his expressions gave offence to the dominant theologians, and he had to save himself by distinguishing his personal faith from his editorial capacity. Achillini, the persistent philosophical adversary of Pomponatius both at Padua and subsequently at Bologna, attempted, along with other moderate but not brilliant Averroists, to accommodate their philosophical theory with the requirements of Catholicism. It was this comparatively mild Averroism, reduced to the merely explanatory activity of a commentator, which continued to be the official dogma at Padua during the 16th century. Its typical representative is Marc-Antonio Zimara (d. 1552), the author of a reconciliation between the tenets of Averroes and those of Aristotle.

Meanwhile, in 1497, Aristotle was for the first time expounded in Greek at Padua. Plato had long been the favourite study at Florence; and Humanists, like Erasmus, Ludovicus Vives, and Nizolius, enamoured of the popular philosophy of Cicero and Quintilian, poured out the vials of their contempt on scholastic barbarism with its "impious and thrice-accursed Averroes." The editors of Averroes complain that the popular taste had forsaken them for the Greek. Nevertheless, while Fallopius, Vesalius, and Galileo were claiming attention to their discoveries, the Professors Zabarella, Piccolomini, Pendasio, and Cremonini continued the traditions of Averroism, not without changes and additions. Cremonini, the last of them, died in 1631, after lecturing twelve years at Ferrara, and forty at Padua. The legend which tells that he laid aside his telescope rather than see Jupiter's moons, which Galileo had discovered, is a parable of the fall of scholastic Averroism. Mediævalism, with its misconstruction of Averroes, perished because it would not see that the interpretation of the past calls for the ripest knowledge of all discoveries in the present.

The literary works of Averroes include treatises on jurisprudence, grammar, astronomy, medicine, and philosophy. In 1859, a work of Averroes was for the first time published in Arabic by the Bavarian Academy, and a German translation appeared in 1875 by the editor, J. Müller. It is a treatise entitled *Philosophy and Theology*, and, with the exception of a German version of the essay on the conjunction of the intellect with man, is the first translation which enables the non-Semitic scholar to form any adequate idea of Averroes. The Latin translations of most of his works are barbarous and obscure. A great part of his writings, particularly on jurisprudence and astronomy, as well as essays on special logical subjects, prolegomena to philosophy, criticisms on Avicenna and Alfarabius, remain in manuscript in the Escorial and other libraries. The Latin editions of his medical works include the *Colliget* (*i.e.*, Kulliyyat, or summary), a *résumé* of medical science, and a commentary on Avicenna's poem on medicine; but Averroes, in medical renown, always stood far inferior to Avicenna. The Latin editions of his philosophical works comprise the *Commentaries on Aristotle*, the *Destructio Destructionis* (against Algazali), the *De Substantia Orbis*, and a double treatise *De Animæ Beatitudine*. The Commentaries of Averroes fall under three heads:—the larger commentaries, in which a paragraph is quoted at large, and its clauses expounded one by one; the medium commentaries, which cite only the first words of a section; and the paraphrases or analyses, treatises on the subjects of the Aristotelian books. The larger commentary was an innovation of Averroes; for Avicenna, copied by Albertus Magnus, gave under the rubrics furnished by Aristotle works in which, though the materials were borrowed, the grouping was his own. The great

commentaries exist only for the *Posterior Analytics*, *Physics*, *De Cœlo*, *De Anima*, and *Metaphysics*. On the *History of Animals* no commentary at all exists, and Plato's *Republic* is substituted for the then inaccessible *Politics*. The Latin editions of these works between 1480 and 1580 number about 100. The first appeared at Padua, 1472; about fifty were published at Venice, the best known being that by the Juntas (1552-3), in ten volumes folio.

Mittelalters*, ii. 67-124; Averroes (Vater und Sohn), *Drei Abhandl. über d. Conjunction d. separaten Intellects mit d. Menschen*, translated into German from the Arabic version of Sam. ibn-Tibbon, by Dr J. Hercz, Berlin, 1869. (W. W.)

AVERSA, a town of Italy, province of Terra di Lavoro, situated in a beautiful plain covered with orange-groves and vineyards, about midway between Naples and Capua. It is the seat of a wealthy bishopric, and its foundling hospital and lunatic asylum, the latter founded by Murat, are very celebrated. Aversa owed its origin to the Normans, and dates from 1030, the people of the ancient city of Atella being transported thither. Population, 21,176.

AVESNES, a town of France, in the department of Nord, situated in a fertile district on the Greater Helpe. It is generally well built, and is fortified on Vauban's system. Its principal building is the cathedral, surmounted by a tower 330 feet high, which is raised on four columns, and has a fine chime. It is the seat of a sub-prefect, and has a tribunal of primary jurisdiction, an agricultural society, and a communal college. The principal manufactures are hosiery, coarse serge, and soap; there are also breweries, tanneries, salt-refineries, and brick and marble works. A great part of the town was destroyed by the explosion of a powder-magazine during the siege by the Prussians in July 1815, but was soon afterwards rebuilt. Population, 3737.

AVEYRON, a department in the S. of France, bounded on the N. by Cantal, E. by Lozère, S. by Hérault and Tarn, and W. by Tarn et-Garonne and Lot, containing an area of 3429 square miles. It corresponds to a large portion of the ancient district of Rouergue in Guienne, which formerly gave its name to a family of counts. Its earliest inhabitants known to us were the Rutheni, whose capital was Segodunum, identified with the modern Rodez. The department is rich in prehistoric antiquities, such as the dolmens at Taurines, Laumières, Grailhe, &c. (see paper by M. E. Cartailhac in Norwich vol. of *Internat. Cong. of Prehist. Arch.*, 1868). A large portion of Aveyron is occupied by offshoots of the Cevennes, the highest summit being Cham-de-la-Roche, 4350 feet above the level of the sea. About half the area is under cultivation, nearly one-fourth is heath, one-tenth woods and forests, and rather more than an eighth part meadow land. Vineyards occupy about one-twelfth part of the cultivated land. The department has mines of copper, lead, silver, iron, zinc, alum, and antimony, and extensive coal-fields of great value. Rather more than three-fourths of the inhabitants are engaged in agricultural pursuits of one kind or another,—mainly in the rearing of cattle, sheep, and swine; and there are manufactures of paper, woollen and cotton goods, silk, and leather, to which water-power is skilfully applied. Aveyron exports chestnuts, almonds, hemp, wool, wax, the famous Roquefort cheese, timber, and cattle. Among the numerous men of mark belonging to the department may be mentioned Jean de la Valette, the defender of Malta, Raynal, Bonald, and Louis Blanc. The capital is Rodez, and the arrondissements are Rodez, Espalion, Millhau, Saint-Affrique, and Villefranche. Population in 1872, 402,474. For investigations into the races represented in the department see *Bulletins de la Soc. d'Anthrop.* vol. iv.

AVEZZANO, a town of Italy, in Abruzzo Ulteriore II., containing a castle, which was built in 1499 by Virgilio Orsini, afterwards belonged to the family of the Colonnas, and is now in the possession of the Barberinis. Population about 5900. Long. 13° 32′ E., lat. 41° 58′ N.

AVICEBRON. The writer referred to by the Scholastics of the 13th century under this name was supposed by them to be an Arabian philosopher, and was accordingly classed along with Avempace, Abubacer, and others. Recent researches have shown that this is an error, and that this author, about whom so little was known, is identical with Salomon ben Gebirol, a Jewish writer, several of whose religious poems are still celebrated among the Jews. Few details are known regarding the life of Gebirol. He was born at Malaga, and received his education at Saragossa, where, in 1045, he wrote a small treatise on morals, which has been several times reprinted. His death is said to have taken place in 1070 at Valencia. Among the Jews he is known only through his poems, and, with a few unimportant exceptions, no Jewish writer refers to his philosophical speculations. The Christian Schoolmen, about the middle of the 12th century, became acquainted with Gundisalvi's Latin translation of a work called *Fons Vitæ* or *Sapientiæ*, which exercised a powerful influence on their metaphysical discussions. The author was called by them Avicebron, or Avicembron, or Avencebrol, and nothing was known regarding him till M. Munk discovered a Hebrew abridgment, by Ibn Falaquéra, of Rabbi S. ben Gebirol's treatise on the source of life. He readily identified this with the work of the unknown Avicebron, and the discovery of two Latin MSS. of the *Fons* has placed the identification beyond doubt. The extracts of Falaquéra give a fair idea of the work, and enable us to understand the peculiar influence it exercised. The objects of metaphysics according to it are three in number, the knowledge of matter and form, of the divine will or creative word, and of the supreme unity of God. God, as infinite, cannot be known by intelligence which is finite, for all knowledge involves comprehension, or requires that the known be contained in the knowing. God works through the divine will, which is intermediate between the supreme unity and the world. All things in the world possess both matter and form; all the various species of matter are but variations of one universal matter; and similarly all forms are contained in one universal form. This unity of matter applies to the soul and mind as well as to material things, and it is against this proposition that the orthodox Schoolmen, as Albertus and Thomas, principally argue. The matter and form in the universe is disposed in successive stages, and rising above the lowest grade or corporal matter there are certain intermediate substances uniting it with the divine will, without which there is no motion. These intermediate substances, taken in order, are —the universal intellect, the rational soul, the vital soul, the vegetative soul, and nature, or the principle of motion in material things. Activity is transmitted from the divine will through these stages, each of which causes the one next below itself to pass from potentiality into actuality. The materials of Avicebron's philosophy are due mainly to the Alexandrian speculations concealed in the pseudo-Aristotelian *Theology*. The position of the divine will, somewhat enigmatical in a philosophical point of view, is probably a concession to Jewish orthodoxy. For a full account of all that is known regarding Avicebron's life and philosophy, with translation of Falaquéra's extracts, see Munk's *Mélanges de Phil. Juive et Arabe*, pp. 1-306; for his poems see Sachs's *Die Religiöse Poesie der Juden in Spanien*, and Geiger's *S. ben Gabirol und seine Dichtungen*.

AVICENNA (in Arabic, Abû Ali el-Hosein Ibn-Abdallah Ibn-Sina) was born about the year 980 A.D. at Afshena, one of the many hamlets in the district of Bokhara. His mother was a native of the place; his father, a Persian

from Balkh, filled the post of tax-collector in the neighbouring town of Harmaitin, under Nûh ibn Mansîr, the Samanide emir of Bokhara. On the birth of Avicenna's younger brother the family migrated to the capital, then one of the chief cities of the Moslem world, and famous for a culture which was older than its conquest by the Saracens. Avicenna was put in charge of a tutor, and his precocity soon made him the marvel of his neighbours,—as a boy of ten who knew by rote the Koran and much Arabic poetry besides. From a greengrocer he learnt arithmetic; and higher branches were begun under one of those wandering scholars, who gained a livelihood by cures for the sick and lessons for the young. Under him Avicenna read the *Isagoge* of Porphyry, and the first propositions of Euclid. But the pupil soon found his teacher to be but a charlatan, and betook himself, aided by commentaries, to master logic, geometry, and the Almagest. Before he was sixteen he not merely knew medical theory, but by gratuitous attendance on the sick had, according to his own account, discovered new methods of treatment. For the next year and a half he worked at the higher philosophy, in which he encountered greater obstacles. In such moments of baffled inquiry he would leave his books, perform the requisite ablutions, then hie to the mosque, and continue in prayer till light broke on his difficulties. Deep into the night he would continue his studies, stimulating his senses by occasional cups of wine, and even in his dreams problems would pursue him and work out their solution. Forty times, it is said, he read through the metaphysics of Aristotle, till the words were imprinted on his memory; but their meaning was hopelessly obscure, until one day they found illumination from the little commentary by Alfarabius, which he bought at a bookstall for the small sum of three drachmæ. So great was his joy at the discovery, thus made by help of a work from which he had expected only mystery, that he hastened to return thanks to God, and bestowed an alms upon the poor. Thus, by the end of his seventeenth year, he had gone the round of the learning of his time; his apprenticeship of study was concluded, and he went forth a master to find a market for his accomplishments.

His first appointment was that of physician to the emir, whom the fame of the youthful prodigy had reached, and who owed him his recovery from a dangerous illness. Avicenna's chief reward for this service was access to the royal library, contained in several rooms, each with its chests of manuscripts in some branch of learning. The Samanides were well-known patrons of scholarship and scholars, and stood conspicuous amid the fashion of the period, which made a library and a learned retinue an indispensable accompaniment of an emir, even in the days of campaign. In such a library Avicenna could inspect works of great rarity, and study the progress of science. When the library was destroyed by fire not long thereafter, the enemies of Avicenna accused him of burning it, in order for ever to conceal the sources of his knowledge. Meanwhile, he assisted his father in his financial labours, but still found time to write some of his earliest works for two wealthy patrons, whose absolute property they became. Among them was the *Collectio*, one of those short synopses of knowledge which an author threw off for different patrons.

At the age of twenty-two Avicenna lost his father. The Samanide dynasty, which for ten years had been hard pressed between the Turkish Khan of Kashgar on the north and the rulers of Ghazni on the south, came to its end in December 1004. Avicenna seems to have declined the offers of Mahmud the Ghaznevide (who, like his compeers, was rapidly gathering a brilliant cortege of savants, including the astronomer Albiruni), and proceeded westwards to the city of Urdjensh in the modern district of Khiva, where the vizier, regarded as a friend of scholars, gave him a small monthly stipend. But the pay was small, and Avicenna wandered from place to place through the districts of Nishapur and Merv to the borders of Khorasan, seeking an opening for his talents. In the restless change which threw the several cities of Iran from hand to hand among those feudal emirs of the Buide family, who disputed the fragments of the caliphate, the interests of letters and science were not likely to be regarded. Shems al-Maâli Kabûs, the generous ruler of Deilem, himself a poet and a scholar, with whom he had expected to find an asylum, was about that date (1013) starved to death by his own revolted soldiery. Avicenna himself was at this season stricken down by a severe illness. Finally, at Jorjân, near the Caspian, he met with a friend, who bought near his own house a dwelling in which Avicenna lectured on logic and astronomy. For this patron several of his treatises were written; and the commencement of his *Canon of Medicine* also dates from his stay in Hyrcania.

He subsequently settled at Rai, in the vicinity of the modern Teheran, where a son of the last emir, Medj Addaula, was nominal ruler, under the regency of his mother. At Rai about thirty of his shorter works are said to have been composed. But the constant feuds which raged between the regent and her second son, Shems Addaula, compelled the scholar to quit the place, and after a brief sojourn at Kaswîn, he passed southwards to Hamadân, where that prince had established himself. At first he entered into the service of a high-born lady; but ere long the emir, hearing of his arrival, called him in as medical attendant, and sent him back with presents to his dwelling. Avicenna was even raised to the office of vizier; but the turbulent soldiery, composed of Koords and Turks, mutinied against their nominal sovereign, and demanded that the new vizier should be put to death. Shems Addaula consented that he should be banished from the country. Avicenna, however, remained hidden for forty days in a sheikh's house, till a fresh attack of illness induced the emir to restore him to his post. Even during this perturbed time he prosecuted his studies and teaching. Every evening extracts from his great works, the *Canon* and the *Sanatio*, were dictated and explained to his pupils; among whom, when the lesson was over, he spent the rest of the night in festive enjoyment with a band of singers and players. On the death of the emir Avicenna ceased to be vizier, and hid himself in the house of an apothecary, where, with intense assiduity, he continued the composition of his works. Meanwhile, he had written to Abu Jaafar, the prefect of Ispahan, offering his services; but the new emir of Hamadân getting to hear of this correspondence, and discovering the place of Avicenna's concealment, incarcerated him in a fortress. War meanwhile continued between the rulers of Ispahan and Hamadân; in 1024 the former captured Hamadân and its towns, and expelled the Turkish mercenaries. When the storm had passed Avicenna returned with the emir to Hamadân, and carried on his literary labours; but at length, accompanied by his brother, a favourite pupil, and two slaves, made his escape out of the city in the dress of a Sufite ascetic. After a perilous journey they reached Ispahan, and received an honourable welcome from the prince. The remaining ten or twelve years of Avicenna's life were spent in the service of Abu Jaafar Ala Addaula, whom he accompanied as physician and general literary and scientific adviser, even in his numerous campaigns. During these years he began to study literary matters and philology, instigated, it is asserted, by criticisms on his style. But amid his restless study Avicenna never forgot his love of enjoyment. Unusual bodily vigour enabled him to combine severe

devotion to work with facile indulgence in sensual pleasures. His passion for wine and women was almost as well known as his learning. With much gaiety of heart, and great powers of understanding, he showed at the same time the spirit of an Aristippus more than that of an Aristotle at the courts of the wealthy. Versatile, light-hearted, boastful, and pleasure-loving, he contrasts with the nobler and more intellectual character of Averroes. His bouts of pleasure gradually weakened his constitution; a severe colic, which seized him on the march of the army against Hamadân, was checked by remedies so violent that Avicenna could scarcely stand. On a similar occasion the disease returned; with difficulty he reached Hamadân, where, finding the disease gaining ground, he refused to keep up the regimen imposed, and resigned himself to his fate. On his deathbed remorse seized him; he bestowed his goods on the poor, restored unjust gains, freed his slaves, and every third day till his death listened to the reading of the Koran. He died in June 1037, in his 58th year, and was buried among the palm-trees by the Kiblah of Hamadân.

It was mainly accident which determined that from the 12th to the 17th century Avicenna should be the guide of medical study in European universities, and eclipse the names of Rhazes, Ali, and Avenzoar. His work is not essentially different from that of his predecessors Rhazes and Ali; all present the doctrine of Galen, and through Galen the doctrine of Hippocrates, modified by the system of Aristotle. But the *Canon* of Avicenna is distinguished from the *El-Hawi* (*Continens*) or *Summary* of Rhazes by its greater method, due perhaps to the logical studies of the former, and entitling him to his surname of Prince of the Physicians. The work has been variously appreciated in subsequent ages, some regarding it as a treasury of wisdom, and others, like Avenzoar, holding it useful only as waste paper. In modern times it has been more criticised than read. The vice of the book is excessive classification of bodily faculties, and over-subtlety in the discrimination of diseases. It includes five books; of which the first and second treat of physiology, pathology, and hygiene, the third and fourth deal with the methods of treating disease, and the fifth describes the composition and preparation of remedies. This last part contains some contingent of personal observation. He is, like all his countrymen, ample in the enumeration of symptoms, and is said to be inferior to Ali in practical medicine and surgery. He introduced into medical theory the four causes of the Peripatetic system. Of natural history and botany he pretends to no special knowledge. Up to the year 1650, or thereabouts, the *Canon* was still used as a text-book in the universities of Louvain and Montpellier.

The rank of Avicenna in the mediæval world as a philosopher was far beneath his fame as a physician. Still, the logic of Albertus Magnus and succeeding doctors was largely indebted to him for its formulæ. In logic Avicenna starts from distinguishing between the isolated concept and the judgment or assertion; from which two primitive elements of knowledge there is artificially generated a complete and scientific knowledge by the two processes of definition and syllogism. But the chief interest for the history of logic belongs to his doctrine in so far as it bears upon the nature and function of abstract ideas. The question had been suggested alike to East and West by Porphyry, and the Arabians were the first to approach the full statement of the problem. Alfarabius had pointed out that the universal and individual are not distinguished from each other as understanding from the senses, but that both universal and individual are in one respect intellectual, just as in another connection they play a part in perception. He had distinguished the universal essence in its abstract nature, from the universal considered in relation to a number of singulars. These suggestions formed the basis of Avicenna's doctrine. The essences or forms—the *intelligibilia* which constitute the world of real knowledge—may be looked at in themselves (metaphysically), or as embodied in the things of sense (physically), or as expressing the processes of thought (logically). The first of these three points of view deals with the form or idea as self-contained in the principles of its own being, apart from those connections and distinctions which it receives in real (sensuous) science, and through the act of intellect. Secondly, the form may be looked at as the similarity evolved by a process of comparison, as the work of mental reflection, and in that way as essentially expressing a relation. When thus considered as the common features derived by examination from singular instances, it becomes a universal or common term strictly so called. It is intellect which first makes the abstract idea a true universal. (*Intellectus in formis agit universalitatem.*) In the third place, the form or essence may be looked upon as embodied in outward things (*in singularibus propriis*), and thus it is the type more or less represented by the members of a natural kind. It is the designation of these outward things which forms the "first intention" of names; and it is only at a later stage, when thought comes to observe its own modes, that names, looked upon as predicables and universals, are taken in their "second intention." Logic deals with such second intentions. It does not consider the forms *ante multiplicitatem*, *i.e.*, as eternal ideas—nor *in multiplicitate*, *i.e.*, as immersed in the matter of the phenomenal world—but *post multiplicitatem*, *i.e.*, as they exist in and for the intellect which has examined and compared. Logic does not come in contact with things, except as they are subject to modification by intellectual forms. In other words, universality, individuality, and speciality are all equally modes of our comprehension or notion; their meaning consists in their setting forth the relations attaching to any object of our conception. In the mind, *e.g.*, one form may be placed in reference to a multitude of things, and as thus related will be universal. The form animal, *e.g.*, is an abstract intelligible, or metaphysical idea. When an act of thought employs it as a schema to unify several species, it acquires its logical aspect (*respectus*) of generality; and the various living beings qualified to have the name animal applied to them constitute the natural class or kind. Avicenna's view of the universal may be compared with that of Abelard, which calls it "that whose nature it is to be predicated of several," as if the generality became explicit only in the act of predication, in the *sermo* or proposition, and not in the abstract, unrelated form or essence. The three modes of the universal before things, in things, and after things, spring from Arabian influence, but depart somewhat from his stand-point.

The place of Avicenna amongst Moslem philosophers is seen in the fact that Shahrastani takes him as the type of all, and that Algazali's attack against philosophy is in reality almost entirely directed against Avicenna. His system is in the main a codification of Aristotle modified by fundamental views of Neo-Platonist origin, and it tends to be a compromise with theology. In order, for example, to maintain the necessity of creation, he taught that all things except God were admissible or possible in their own nature, but that certain of them were rendered necessary by the act of the creative first agent,—in other words, that the possible could be transformed into the necessary. Avicenna's theory of the process of knowledge is an interesting part of his doctrine. Man has a rational soul, one face of which is turned towards the body, and, by the help of the higher aspect, acts as practical understanding; the other face lies open to the reception and acquisition of the intelligible forms, and its aim is to become a reason-

able world, reproducing the forms of the universe and their intelligible order. In man there is only the susceptibility to reason, which is sustained and helped by the light of the active intellect. Man may prepare himself for this influx by removing the obstacles which prevent the union of the intellect with the human vessel destined for its reception. The stages of this process to the acquisition of mind are generally enumerated by Avicenna as four; in this part he follows not Aristotle, but the Greek commentator. The first stage is that of the hylic or material intellect, a state of mere potentiality, like that of a child for writing, before he has ever put pen to paper. The second stage is called *in habitu*; it is compared to the case of a child that has learned the elements of writing, when the bare possibility is on the way to be developed, and is seen to be real. In this period of half-trained reason, it appears as happy conjecture, not yet transformed into art or science proper. When the power of writing has been actualised, we have a parallel to the *intellectus in actu*—the way of science and demonstration is entered. And when writing has been made a permanent accomplishment, or lasting property of the subject, to be taken up at will, it corresponds to the *intellectus adeptus*—the complete mastery of science. The whole process may be compared to the gradual illumination of a body naturally capable of receiving light. There are, however, grades of susceptibility to the active intellect, *i.e.*, in theological language, to communication with God and his angels. Sometimes the receptivity is so vigorous in its affinity, that without teaching it rises at one step to the vision of truth, by a certain "holy force" above ordinary measure. (In this way philosophy tried to account for the phenomenon of prophecy, one of the ruling ideas of Islam.) But the active intellect is not merely influential on human souls. It is the universal giver of forms in the world.

In several points Avicenna endeavoured to give a *rationale* of theological dogmas, particularly of prophetic rule, of miracles, divine providence, and immortality. The permanence of individual souls he supports by arguments borrowed from those of Plato. The existence of a prophet is shown to be a corollary from a belief in God as a moral governor, and the phenomena of miracles are required to evidence the genuineness of the prophetic mission. For man, in order to his well-being and the permanence of his kind, requires in the first place a clear vision of right and truth, and must, secondly, depend upon some power capable of carrying out these discoveries of moral law. If providence has so arranged that the eyelids and the hair of the eyebrows shall grow to protect the eye, much more is it needful for a prophet to arise who shall preach the truth of God's unity, prescribe laws for men, and exhort them to well-doing by the promise of recompense to come. The weal of humanity demands the revelation from God, and, to certify his office, the prophet must work miracles. Just as in ordinary states the soul influences the bodily organs, so in exalted conditions it may attain the level of those high immaterial spirits, whose energy is strong enough to permeate the whole passive world. This mystical union with the hidden universe is a mystery which the ordinary mind cannot understand. Many things then become visible as by a lightning flash in the darkness, and are apprehended by the vigorous grasp of pure intuition. But more generally the imagination throws itself on these intuitions, and presents them to the lower soul under the semblance of forms and sounds—the angelic beauty which the seer beholds, and the harmonious speech which a heavenly voice seems to utter in his ear. Thus Avicenna, like his predecessors, tried to harmonise the abstract forms of philosophy with the religious faith of his nation. But his arguments are generally vitiated by the fallacy of assuming what they profess to prove. His failure is made obvious by the attack of Algazali on the tendencies and results of speculation.

Upwards of 100 treatises are ascribed to Avicenna. Some of them are tracts of a few pages, others are works extending through several volumes. The best-known amongst them, and that to which Avicenna owed his European reputation, is the *Canon of Medicine*; an Arabic edition of it appeared at Rome 1593, and a Hebrew version at Naples in 1491. Of the Latin version there were about thirty editions, founded on the original translation by Gerard of Cremona. The 15th century has the honour of composing the great commentary on the text of the *Canon*, grouping around it all that theory had imagined, and all that practice had observed. Other medical works translated into Latin are the *Medicamenta Cordialia*, *Canticum de Medicina*, *Tractatus de Syrupo Acetoso*. Scarcely any member of the Arabian circle of the sciences, including theology, philology, mathematics, astronomy, physics, and music, has been left untouched by the treatises of Avicenna, many of which probably varied little, except in being commissioned by a different patron and having a different form or extent. He wrote at least one treatise on alchemy, but several others have been falsely attributed to him. His book on animals was translated by Michael Scot. His *Logic*, *Metaphysics*, *Physics*, *De Cœlo*, are treatises giving a synoptic view of Aristotelian doctrine. The *Logic* and *Metaphysics* have been printed more than once; the latter, *e.g.*, at Venice in 1493, 1495, and 1546. Some of his shorter essays on medicine, logic, &c., take a poetical form (the poem on logic was published by Schmœlders in 1836). Two encyclopædic treatises, dealing with philosophy, are often mentioned. The larger, *Al-Shefa* (*Sanatio*), exists nearly complete in manuscript in the Bodleian Library and elsewhere; part of it on the *De Anima* appeared at Pavia (1490) as the *Liber Sextus Naturalium*, and the long account of Avicenna's philosophy given by Shahrastani seems to be mainly an analysis, and in many places a reproduction, of the *Al-Shefa*. A shorter form of the work is known as the *Al-Nedjat* (*Liberatio*). The Latin editions of part of these works have been modified by the corrections which the monkish editors confess that they applied. There is also a *Philosophia Orientalis*, mentioned by Roger Bacon, and now lost, which according to Averroes was pantheistic in tone.

For Avicenna's life, see Ibn Khallikan's *Biographical Dictionary*, translated by Slane (1842); Wüstenfeld's *Geschichte der Arabischen Aerzte und Naturforscher*, Göttingen, 1840; Abul-Pharagius, *Historia Dynastiarum*. For his medicine, see Sprengel, *Histoire de la Médecine*; and for his philosophy, see Shahrastani, Germ. transl. vol. ii. 213–332; Prantl, *Geschichte der Logik*, ii. 318–361; Stöckl, *Phil. d. Mittelalters*, ii. 23–58; Munk, *Mélanges*, 352–366; and Haneberg in the *Abhandlungen der Philos.-Philolog. Class. der Bayerischen Academie*, 1867. (W. W.)

AVIENUS, Rufus Festus, a Latin poet, who appears to have flourished in the latter half of the 4th century. Any knowledge we have of the facts of his life is derived from a Latin inscription, printed by Meyer (*Anthologia Latina*, 278), which has been supposed to refer to him. He is in all probability the Festus who was proconsul in Africa in 366 and following years, and in Achaia in 372. He is the author of the following works:—1. *Descriptio Orbis Terræ*, sometimes called *Metaphrasis Periegeseos Dionysii*, being derived from the περιήγησις of that writer; 2. *Ora Maritima*, of which there is extant only a fragment describing the Atlantic coast, and the Mediterranean as far as Marseilles; 3. *Aratea Phænomena*, and *Aratea Prognostica*, which are paraphrases of two works of Aratus. These poems, with the exception of the *Aratea*, are contained in Wernsdorf's *Poëtæ Latini Minores*, vol. v. pt. ii.

AVIGLIANO, a town of Italy, in the province of Basilicata, 11 miles N.N.W. of Potenza. It stands on the declivity of a hill, and contains a collegiate church, several convents, and a royal college. A peculiar kind of pottery produced here towards the end of the 18th century is still sought after by collectors. The surrounding country is said to produce the finest cattle in the kingdom. A part of the town was destroyed by a land-slip in 1824. Population, 15,982.

AVIGNON, the chief town of the department of Vaucluse in France, situated in a beautiful plain, on the left bank of the Rhone, not far from the entrance of the Durance. It is surrounded by its ancient crenellated walls, which are in a state of remarkable preservation,

and, on the outside, by a line of pleasant boulevards planted with trees. A precipitous rock rises from the river's edge; and from its summit the cathedral of *Nôtre Dame des Doms*, a building of the 12th century, looks down on the city, but is almost thrown into insignificance by the Palace of the Popes, which rises by its side, and

stretches in sombre grandeur along the southern slope. This building, or congeries of buildings, was commenced by Benedict XII. in 1336, and continued by successive popes for sixty years. It covers an area of rather more than 1¼ acres. The paintings with which it was profusely adorned are in great measure destroyed, and even the grandeur of its dismantled interiors was for a long time broken in upon by the carpentry and plaster-work of French barracks. A restoration has, however, been for some time in progress; and the building will again be appropriated for ecclesiastical and civic purposes. The churches of St Agricol, St Didier, and St Pierre may be mentioned as of some importance; also the papal mint, now known as a music academy; the town-hall, built in 1862; the Calvet museum, rich in Roman remains; the Requien museum of natural history; and the Hôtel des Invalides. Of the church of the Cordeliers, in which Petrarch's Laura was buried, only a small part is standing, and the tomb itself has been entirely destroyed. The city is the seat of an archbishop, and has tribunals of primary jurisdiction and commerce, a royal college, a theological seminary, a society of arts, the Vaucluse academy, a public library, a theatre, &c. The chief object of industry is the preparation of silk and the manufacture of silk goods; there are also manufactures of paper, leather, hats, jewellery, iron-ware, &c. Avignon is remarkably subject to violent winds, of which the most disastrous is the *mistral*; and, according to the proverb, *Avenio ventosa, sine vento venenosa, cum vento fastidiosa* (windy Avignon, liable to plague when it has not the wind, and plagued with the wind when it has it). The town was a place of some importance in the times of Roman supremacy, and seems to have had some special connection with the Greek colony at Massilia. It was incorporated with the Burgundian kingdom, and on its dissolution became a free republic, after the Italian type. As late, indeed, as 1790, it retained its consuls, though its republican constitution was really destroyed by Charles of Anjou. From 1309, when Clement V. took up his abode in the city, to 1377, when Gregory XI. returned to Rome, Avignon was the seat of the papal court, and it continued from 1378 to 1418 to be the seat of French anti-popes. In 1348 it was purchased by Pope Clement VI. from Joanna of Sicily for the sum of 80,000 florins, and it remained in possession of the popes till the French Revolution. Population in 1872, 38,196.

AVILA, a province of Spain, one of the modern divisions of the kingdom of Old Castile, situated between long. 4° 14′ and 5° 55′ W., and lat. 40° 48′ and 41° 18′ N. It is bounded on the N. by Valladolid, E. by Segovia and Madrid, S. by Toledo and Caceres, and W. by Salamanca. The area is 2570 square miles; population, 176,769. It naturally divides itself into two sections, differing completely in soil, climate, productions, and social economy. The northern portion is generally level; the soil is of indifferent quality, strong and marly in a few places, but rocky in all the valleys of the Sierra de Avila; and the climate alternates from severe cold in winter to extreme heat in summer. The population of this part is agricultural. The southern division is one mass of rugged granitic *sierras*, interspersed, however, with sheltered and well-watered valleys, abounding with rich vegetation. The winter here, especially in the elevated region of the Paramera and the waste lands of Avila, is long and severe, but the climate is not unhealthy. The inhabitants are occupied in the rearing of cattle. The principal mountain chains are the Guadarrama, separating this province from Madrid; the Sierras de Avila, a continuation of them westward; the Sierra de Gredos, running from the south of Piedrahita through Barco, Arenos, and part of Cebreros; and the Paramera, stretching southwards from the city of Avila into Arenas and Cebreros. The various ridges which ramify from the latter are covered with wood, presenting a striking contrast to the bare peaks of the Sierra de Gredos, and the barren levels in which they rise on the north. The principal rivers are the Alberche and Tietar, belonging to the basin of the Tagus, and the Tormes, the Corneja, and the Adaja, belonging to that of the Douro. The mountains contain silver, copper, iron, lead, and coal, but their mineral wealth has been exaggerated, and the actual production is absolutely nil. Quarries of fine marble and jasper exist in the district of Arenas. The province has declined in wealth and population during the last two centuries, a result due less to the want of activity on the part of the inhabitants than to the oppressive manorial and feudal rights and the strict laws of entail and mortmain, which have acted as barriers to improvement. The principal production is the wool of the Merino sheep, which at one time yielded an immense revenue. Game is plentiful, and the rivers abound in fish, specially trout. Olives, chestnuts, and grapes are grown, and the culture of silk-worms is also carried on. There is little trade, and the manufactures are few, consisting chiefly of copper utensils, lime, soap, cloth, paper, combs, &c. The state of elementary education is comparatively good, and the ratio of crime is proportionately low (Madoz, *Diccionario de España*).

AVILA (the ancient *Abula*), a city of Spain, the capital of the above province, is situated on the right bank of the Adaja, about 3000 feet above the sea-level, at the termination of the Guadarrama Mountains. "On all sides," says a recent traveller, "the town is surrounded by a tawny desert, over whose arid plains numbers of gray boulders are scattered like flocks of sheep." Its ancient wall is still in good preservation, crowned by a breastwork, with towers of great strength; but a large part of the town lies beyond the circuit. Avila is the seat of a bishop suffragan to Santiago, and has a Gothic cathedral, built by Garcia

de Estrella in 1107; a number of interesting churches, such as *Santo Tomas*, with the beautiful tomb of Prince Juan, *San Vincenti*, with its remarkable carving, and *Nuestra Seraf. Madre Santa Teresa*, built over the birthplace of the patroness of Spain (who here founded the convent of St Joseph); as well as several monasteries and schools, an infirmary, and a foundling hospital. It was formerly the seat of a university, which was founded in 1482, and changed into the college of St Thomas in 1807. The only manufacture of any importance is the spinning of the wool furnished by the native sheep. Population, 6892.

AVILA, GIL GONZALEZ D', a Spanish biographer and antiquary, was born at Avila about the year 1577, and died there in 1658. He was made historiographer of Castile in 1612, and of the Indies in 1641. Of his numerous works, the most valuable are his *Teatro de las Grandezas de Madrid* (Madrid, 1623, *sqq.*), and his *Teatro Eclesiastico*, descriptive of the metropolitan churches and cathedrals of Castile, with lives of the prelates (Madrid, 1645-53, 4 vols. 4to).

AVILA Y ZUNIGA, LUIS D', author of a Spanish history of the wars of Charles V. Nothing is known as to the place or date either of his birth or of his death. He was probably of low origin, but married a wealthy heiress of the house of Zuniga, whose name he added to his own. He rose rapidly in the favour of the Emperor Charles V., served in the army and as ambassador to Rome, and was present at the funeral of Charles in 1558. His work is entitled *Comentarios de la Guerra de Alemaña, hecha de Carlos V. en el año de* 1546 *y* 1547, and appears to have been printed in 1548. It became very popular, and was translated into English, French, Dutch, German, Italian, and Latin. As was to be expected from the position of the author, the book gave a rather one-sided account of Charles, and its misrepresentations have been severely criticised.

AVILES, SAN NICOLAS DE (the Latin *Flavionavia*), a town of Spain, in the province of Oviedo, about a league from the sea-coast, in lat. 43° 34′ N., long. 5° 58′ W. It has a considerable trade by means of its port, which affords good anchorage for all classes of vessels. There are here some copper works and coal mines, and the stone quarries are extensive and productive. Aviles has two parish churches, a theatre, and a public school. Population, 3297.

AVLONA, or VALONA (the ancient Αὐλών), a town and seaport of Albania, in the eyalet of Yanina. It stands on an eminence near the Gulf of Avlona, an inlet of the Adriatic, almost surrounded by mountains. The port, which is protected by the island of Sasseno, the ancient Saso, is the best on the Albanian coast. It is visited weekly by Austrian steamers, and carries on considerable intercourse with Brindisi, &c. The town is about a mile and a half from the sea, and has rather a pleasant appearance with its minarets and its palace, surrounded with gardens and olive-groves. The Christian population, of which a considerable proportion are Italians, is largely engaged in commerce; while the Turks manufacture woollen stuffs and arms. The material imported into England for tanning, under the name of *Valonia*, is the pericarp of an acorn produced in the district. Avlona played an important part in the wars between the Normans and the Byzantine empire. In 1464 it was taken by the Ottomans; and after being in Venetian possession in 1690, was restored to them in 1691. In 1851 it suffered severely from an earthquake.

AVOIRDUPOIS, or AVERDUPOIS, the name of a system of weights, commonly supposed to be derived from the French, *avoir du pois*, to have weight. The suggested derivation from *averer*, to verify, seems, however, more probable, *averdupois* being the earlier form of the word. Avoirdupois weight is used for all commodities except the precious metals, gems, and medicines. The pound avoirdupois, which is equal to 7000 grains troy, or 453·54 grammes, is divided into 16 ounces, and the ounce into 16 drams. See WEIGHTS AND MEASURES.

AVOLA, a city on the coast of Sicily, in the province of Syracuse, with 11,912 inhabitants. It manufactures straw-mats, and has trade in wine, grain, oil, honey, &c.; and there are sugar plantations.

AVON, the name of several rivers in England, Scotland, and France. The word is Celtic, appearing in Welsh as *afon*, in Manx as *aon*, and in Gaelic as *abhuinn* (pronounced *avain*), and is radically identical with the Sanskrit *ap*, water, and the Latin *aqua* and *amnis*. The root appears more or less disguised in a vast number of river names all over the Celtic area in Europe. Thus, besides such forms as *Evan*, *Aune*, *Anne*, *Ive*, *Auney*, *Inney*, &c., in the British Islands, we have *Aff* and *Aven* in Brittany, *Avenza* and *Avens* in Italy, *Avia* in Portugal, and *Avono* in Spain; while the terminal syllable of a large proportion of the French rivers, such as the *Sequana*, the *Matrona*, the *Garumna*, and so on, seems originally to have been the same word. The names Punj*ab*, Do*ab*, &c., show the root in a clearer shape. (See Taylor's *Words and Places*.) Of the principal English rivers of this name in its full form three belong to the basin of the Severn. The Upper or Shakespearean Avon, rising in Northamptonshire, near the battlefield of Naseby, flows through Warwickshire, Worcester, and Gloucester, past Rugby, Warwick, Stratford, and Evesham, and joins the larger river at Tewkesbury; while the Lower Avon has its sources on the borders of Wiltshire, and enters the estuary of the Severn at King's Roads, after passing Malmesbury, Bath, and Bristol. (See Ireland's *Upper Avon*; Lewis's *Book of English Rivers*, 1855.) The Middle or Little Avon has its whole course in Gloucestershire, and reaches the Severn a short distance below the town of Berkeley. Another river of this name rises in Wilts, and flows past Salisbury to the British Channel. In Scotland one is a tributary of the Clyde, another belongs to the basin of the Forth, and a third joins its waters with the Annan, while an *Aven* is a confluent of the Spey. In France there are two "Avons" in the system of the Loire, and two in that of the Seine.

AVRANCHES (ancient *Abrincatæ*, or *Ingena*), a town of France, in the department of Manche. It was an important military station of the Romans, and has in more modern times sustained several sieges, the most noticeable of which was the result of its opposition to Henry IV. It stands on a wooded hill, commanding a fine view of the bay and rock of St Michel, about three miles distant. At the foot of the hill flows the river Sée, which at high tide is navigable from the sea. The principal trade is in corn, cider, and salt; and candles, lace, nails, parchment, leather, &c., are manufactured. Avranches was formerly a bishop's see; and its cathedral, destroyed as insecure in the time of the first French Revolution, was the finest in Normandy. Its site is now occupied by an open *place*, called after the celebrated Huet, bishop of Avranches; and one stone remains with an inscription marking it out as the spot where Henry II. received absolution for the murder of À Becket. Saint-Saturnin's church dates from the 13th century, and has a remarkable gateway. The ancient episcopal palace is now used as a museum of antiquities; and an extensive public library is kept in the "mairie." A new cathedral is in course of erection. The agreeable situation and climate of this town make it a favourite residence of English families. Population in 1872, 8137.

AXHOLM, or AXELHOLM, an island in the N.W. part of Lincolnshire, England, formed by the rivers Trent, Idle, and Don. It consists mainly of a plateau of slight elevation,

and comprises the parishes of Althorpe, Belton, Epworth, Haxey, Luddington, Owston, and Crowle; the total area being about 47,000 acres. At a very early period it would appear to have been covered with forest; but this having been in great measure destroyed, it sank into a comparative swamp. In 1627 King Charles I., who was lord of the island, entered into a contract with Cornelius Vermuyden, a Dutchman, for reclaiming the meres and marshes, and rendering them fit for tillage. This undertaking led to the introduction of a large number of Flemish workmen, who settled in the district, and, in spite of the violent measures adopted by the English peasantry to expel them, retained their ground in sufficient numbers to affect the physical appearance and the accent of the inhabitants to this day. Elaborate volumes have been published on the island by Peck (1815), Stonehouse, and Read. (See paper, by E. Peacock, in *Anthropological Review*, 1870.)

AXIOM, from the Greek ἀξίωμα, is a word of great import both in general philosophy and in special science; it also has passed into the language of common life, being applied to any assertion of the truth of which the speaker happens to have a strong conviction, or which is put forward as beyond question. The scientific use of the word is most familiar in mathematics, where it is customary to lay down, under the name of axioms, a number of propositions of which no proof is given or considered necessary, though the reason for such procedure may not be the same in every case, and in the same case may be variously understood by different minds. Thus scientific axioms, mathematical or other, are sometimes held to carry with them an inherent authority or to be self-evident, wherein it is, strictly speaking, implied that they cannot be made the subject of formal proof; sometimes they are held to admit of proof, but not within the particular science in which they are advanced as principles; while, again, sometimes the name of axiom is given to propositions that admit of proof within the science, but so evidently that they may be straightway assumed. Axioms that are genuine principles, though raised above discussion within the science, are not therefore raised above discussion altogether. From the time of Aristotle it has been claimed for general or first philosophy to deal with the principles of special science, and hence have arisen the questions concerning the nature and origin of axioms so much debated among the philosophic schools. Besides, the general philosopher himself, having to treat of human knowledge and its conditions as his particular subject-matter, is called to determine the principles of certitude, which, as there can be none higher, must have in a peculiar sense that character of ultimate authority (however explicable) that is ascribed to axioms; and by this name, accordingly, such highest principles of knowledge have long been called. In the case of a word so variously employed there is, perhaps, no better way of understanding its proper signification than by considering it first in the historical light—not to say that there hangs about the origin and early use of the name an obscurity which it is of importance to dispel.

The earliest use of the word in a logical sense appears in the works of Aristotle, though, as will presently be shown, it had probably acquired such a meaning before his time, and only received from him a more exact determination. In his theory of demonstration, set forth in the *Posterior Analytics*, he gives the name of axiom to that immediate principle of syllogistic reasoning which a learner must bring with him (i. 2, 6); again, axioms are said to be the common principles from which all demonstration takes place—common to all demonstrative sciences, but varying in expression according to the subject-matter of each (i. 10, 4). The principle of all other axioms—the surest of all principles—is that called later the principle of Contradiction, indemonstrable itself, and thus fitted to be the ground of all demonstration (*Metaph.*, iii. 2, iv. 3). Aristotle's followers, and, later on, the commentators, with glosses of their own, repeat his statements. Thus, according to Themistius (*ad Post. Anal.*), two species of axioms were distinguished by Theophrastus—one species holding of all things absolutely, as the principle (later known by the name) of Excluded Middle, the other of all things of the same kind, as that the remainders of equals are equal. These, adds Themistius himself, are, as it were, connate and common to all, and hence their name Axiom; "for what is put over either all things absolutely or things of one sort universally, we consider to have precedence with respect to them." The same view of the origin of the name reappears in Boethius's Latin substitutes for it—*dignitas* and *maxima* (*propositio*), the latter preserved in the word Maxim, which is often used interchangeably with Axiom. In Aristotle, however, there is no suggestion of such a meaning. As the verb ἀξιοῦν changes its original meaning of *deem worthy* into *think fit*, *think* simply, and also *claim* or *require*, it might as well be maintained that ἀξίωμα—which Aristotle himself employs in its original ethical sense of *worth*, also in the secondary senses of *opinion* or *dictum* (*Metaph.*, iii. 4), and of simple *proposition* (*Topics*, viii. 1)—was conferred upon the highest principles of reasoning and science because the teacher might require them to be granted by the learner. In point of fact, later writers, like Proclus and others quoted by him, did attach to Axiom this particular meaning, bringing it into relation with Postulate (αἴτημα), as defined by Aristotle in the *Posterior Analytics*, or as understood by Euclid in his *Elements*. It may here be added that the word was used regularly in the sense of bare *proposition* by the Stoics (Diog. Laert., vii. 65, though Simplicius curiously asserts the contrary, *ad Epict. Ench.*, c. 58), herein followed in later times by the Ramist logicians, and also, in effect, by Bacon.

That Aristotle did not originate the use of the term axiom in the sense of scientific first principle, is the natural conclusion to be drawn from the reference he makes to "what are called axioms in mathematics" (*Metaph.*, iv. 3). Sir William Hamilton (Note A, Reid's *Works*, p. 765) would have it that the reference is to mathematical works of his own now lost, but there is no real ground for such a supposition. True though it be, as Hamilton urges, that the so-called axioms standing at the head of Euclid's *Elements* acquired the name through the influence of the Aristotelian philosophy, evidence is not wanting that by the time of Aristotle, a generation or more before Euclid, it was already the habit of geometricians to give definite expression to certain fixed principles as the basis of their science. Aristotle himself is the authority for this assertion, when, in his treatise *De Cœlo*, iii. 4, he speaks of the advantage of having definite principles of demonstration, and these as few as possible, such as are postulated by mathematicians (καθάπερ ἀξιοῦσι καὶ οἱ ἐν τοῖς μαθήμασιν), who always have their principles limited in kind or number. The passage is decisive on the point of general mathematical usage, and so distinctly suggests the very word axiom in the sense of a principle assumed or postulated, that Aristotle's repeated instance of what he himself calls by the name—If equals be taken from equals, the remainders are equal—can hardly be regarded otherwise than as a citation from recognised mathematical treatises. The conclusion, if warranted, is of no small interest, in view of the famous list of principles set out by Euclid, which has come to be regarded in modern times as the typical specimen of axiomatic foundation for a science.

Euclid, giving systematic form to the elements of geometrical science in the generation after the death of Aristotle,

propounded, at the beginning of his treatise, under the name of ὅροι, the definitions with which modern readers are familiar; under the name of αἰτήματα, the three principles of construction now called postulates, together with the three theoretic principles, specially geometrical, now printed as the tenth, eleventh, and twelfth axioms; finally, under the name of κοιναὶ ἔννοιαί, or common notions, the series of general assertions concerning equality and inequality, having an application to discrete as well as continuous quantity, now printed as the first nine axioms. Now, throughout the *Elements*, there are numerous indications that Euclid could not have been acquainted with the logical doctrines of Aristotle: a most important one has been signalised in the article ANALYSIS, and, in general, it may suffice to point out that Euclid, who is said to have flourished at Alexandria from 323 (the year of Aristotle's death) to 283 B.C., lived too early to be affected by Aristotle's work—all the more that he was, by philosophical profession, a Platonist. Yet, although Euclid's disposition of geometrical principles at the beginning of his *Elements* is itself one among the signs of his ignorance of Aristotle's logic, it would seem that he had in view a distinction between his postulates and common notions not unlike the Aristotelian distinction between αἰτήματα and ἀξιώματα. All the postulates of Euclid (including the last three so-called axioms) may be brought under Aristotle's description of αἰτήματα—principles concerning which the learner has, to begin with, neither belief nor disbelief, *Post. Anal.*, i. 10, 6); being (as De Morgan interprets Euclid's meaning) such as the "reader must grant or seek another system, whatever be his opinion as to the propriety of the assumption." Still closer to the Aristotelian conception of axioms come Euclid's common notions, as principles "which there is no question every one will grant" (De Morgan). From this point of view, the composition of Euclid's two lists, as they originally stood, becomes intelligible: be this, however, as it may, there is evidence that his enumeration and division of principles were very early subjected to criticism by his followers with more or less reference to Aristotle's doctrine. Apollonius (250-220 B.C.) is mentioned by Proclus (*Com. in Eucl.*, iii.) as having sought to give demonstrations of the common notions under the name of axioms. Further, according to Proclus, Geminus made the distinction between postulates and axioms which has become the familiar one, that they are indemonstrable principles of construction and demonstration respectively. Proclus himself (412-485 A.D.) practically comes to rest in this distinction, and accordingly extrudes from the list of postulates all but the three received in modern times. The list of axioms he reduces to five, striking out as derivative the two that assert inequality (4th and 5th), also the two that assert equality between the doubles and halves of the same respectively (6th and 7th). Euclid's postulate regarding the equality of right angles and the other assumed in the doctrine of parallel lines, now printed as the 11th and 12th axioms, he holds to be demonstrable: the 10th axiom (regarded as an axiom, not a postulate, by some ancient authorities, and so cited by Proclus himself)—Two straight lines cannot enclose a space—he refuses to print with the others, as being a special principle of geometry. Thus he restricts the name axiom to such principles of demonstration as are common to the science of quantity generally. These, he then declares, are principles immediate and self-manifest—untaught anticipations whose truth is darkened rather than cleared by attempts to demonstrate them.

The question as to the axiomatic principles, whether of knowledge in general or of special science, remained where it had thus been left by the ancients till modern times, when new advances began to be made in positive scientific inquiry and a new philosophy took the place of the peripatetic system, as it had been continued through the Middle Ages. It was characteristic alike of the philosophic and of the various scientific movements begun by Descartes to be guided by a consideration of mathematical method—that method which had led in ancient times to special conclusions of exceptional certainty, and which showed itself, as soon as it was seriously taken up again, more fruitful than ever in new results. To establish philosophical and all special truth after the model of mathematics became the direct object of the new school of thought and inquiry, and the first step thither consisted in positing principles of immediate certainty whence deduction might proceed. Descartes accordingly devised his criterion of perfect clearness and distinctness of thought for the determination of ultimate objective truth, and his followers, if not himself, adopted the ancient word axiom for the principles which, with the help of the criterion, they proceeded freely to excogitate. About the same time the authority of all general principles began to be considered more explicitly in the light of their origin. Not that ever such consideration had been wholly overlooked, for, on the contrary, Aristotle, in pronouncing the principles of demonstration to be themselves indemonstrable, had suggested, however obscurely, a theory of their development, and his followers, having obscure sayings to interpret, had been left free to take different sides on the question; but, as undoubtedly the philosophic investigation of knowledge has in the modern period become more and more an inquiry into its genesis, it was inevitable that principles claiming to be axiomatic should have their pretensions scanned from this point of view with closer vision than ever before. Locke it was who, when the Cartesian movement was well advanced, more especially gave this direction to modern philosophic thought, turning attention in particular upon the character of axioms; nor was his original impulse weakened—rather it was greatly strengthened—by his followers' substitution of positive psychological research for his method of general criticism. The expressly critical inquiry undertaken by Kant, at however different a level, had a like bearing on the question as to the nature of axiomatic principles; and thus it has come to pass that the chief philosophic interest now attached to them turns upon the point whether or not they have their origin in experience.

It is maintained, on the one hand, that axioms, like other general propositions, result from an elaboration of particular experiences, and that, if they possess an exceptional certainty, the ground of this is to be sought in the character of the experiences, as that they are exceptionally simple, frequent, and uniform. On the other hand, it is held that the special certainty, amounting, as it does, to positive necessity, is what no experience, under any circumstances, can explain, but is conditioned by the nature of human reason. More it is hardly possible to assert generally concerning the position of the rival schools of thought, for on each side the representative thinkers differ greatly in the details of their explanation, and there is, moreover, on both sides much difference of opinion as to the scope of the question. Thus Kant would limit the application of the name axiom to principles of mathematical science, denying that in philosophy (whether metaphysical or natural), which works with discursive concepts, not with intuitions, there can be any principles immediately certain; and, as a matter of fact, it is to mathematical principles only that the name is universally accorded in the language of special science—not generally, in spite of Newton's lead, to the laws of motion, and hardly ever to scientific principles of more special range like the atomic theory. Other thinkers, however, notably Leibnitz, lay stress on the ultimate principles of all thinking as the only true axioms, and would

contend for the possibility of reducing to these (with the help of definitions) the special principles of mathematics, commonly allowed to pass and do duty as axiomatic. Still others apply the name equally and in the same sense to the general principles of thought and to some principles of special science. In view of such differences of opinion as to the actual matter in question, it is not to be expected that there should be agreement as to the marks characteristic of axioms, nor surprising that agreement, where it appears to exist, should often be only verbal. The character of necessity, for example, so much relied upon for excluding the possibility of an experiential origin, may either, as by Kant, be carefully limited to that which can be claimed for propositions that are at the same time synthetic, or may be vaguely taken (as too frequently by Leibnitz) to cover necessity of mere logical implication—the necessity of analytic, including identical, propositions—which Kant allowed to be quite consistent with origin in experience. The question being so perplexed, no other course seems open than to try to determine the nature of axioms mainly upon such instances as are, at least practically, admitted by all, and these are mathematical principles.

That propositions with an exceptional character of certainty are assumed in mathematical science is notorious; that such propositions must be assumed as principles of the science, if it is to be at once general and demonstrative, is now conceded even by extreme experientialists; while it is, farther, universally held that it is the exceptional character of the subject-matter of mathematics that renders possible such determinate assumption. What the actual principles to be assumed are, has, indeed, always been more or less disputed; but this is a point of secondary importance, since it is possible from different sets of assumption to arrive at results practically the same. The particular list of propositions passing current in modern times as Euclid's axioms, like his original list of common notions, is open to objection, not so much for mixing up assertions not equally underivative (as the ancient critics remarked), but for including two—the 8th and 9th—which are unlike all the others in being mere definitions (viz., of equals and of whole or part). Being intended as a body of principles of geometry in particular within the general science of mathematics, the modern list is not open to exception in that it adds to the propositions of general mathematical import, forming Euclid's original list, others specially geometrical, provided the additions made are sufficient for the purpose. It does, in any case, contain what may be taken as good representative instances of mathematical axioms both general and special; for example, the 1st, Things equal to the same are equal to one another, applicable to all quantity; and the 10th, Two straight lines cannot enclose a space, specially geometrical. (The latter has been regarded by some writers as either a mere definition of straight lines, or as contained by direct implication in the definition; but incorrectly. If it is held to be a definition, nothing is too complex to be so called, and the very meaning of a definition as a principle of science is abandoned; while, if it is held to be a logical implication of the definition, the whole science of geometry may as well be pronounced a congeries of analytic propositions. When straight line is strictly defined, the assertion is clearly seen to be synthetic.) Now of such propositions as the two just quoted it is commonly said that they are self-evident, that they are seen to be true as soon as stated, that their opposites are inconceivable; and the expressions are not too strong as descriptive of the peculiar certainty pertaining to them. Nothing, however, is thereby settled as to the ground of the certainty, which is the real point in dispute between the experiential and rational schools, as these have become determinately opposed since the time and mainly through the influence of Kant. Such axioms, according to Kant, being necessary as well as synthetic, cannot be got from experience, but depend on the nature of the knowing faculty; being immediately synthetic, they are not thought discursively but apprehended by way of direct intuition. According to the experientialists, as represented by J. S. Mill, they are, for all their certainty, inductive generalisations from particular experiences; only the experiences are peculiar (as already said) in being extremely simple and uniform, while the experience of space—Mill does not urge the like point as regards number—is farther to be distinguished from common physical experience in that it supplies matter for induction no less in the imaginative (representative) than in the presentative form. Mill thus agrees with Kant on a vital point in holding the axioms to be synthetic propositions, but takes little or no account of that which, in Kant's eyes, is their distinctive characteristic—their validity as universal truths in the guise of direct intuitions or singular acts of perception, presentative or representative. The synthesis of subject and predicate, thus universally valid though immediately effected, Kant explains by supposing the singular presentation or representation to be wholly determined from within through the mind's spontaneous act, instead of being received as sensible experience from without; to speak more precisely, he refers the apprehension of quantity, whether continuous or discrete, to "productive imagination," and regards it always as a pure mental construction. Mill, who supposes all experience alike to be passively received, or, at all events, makes no distinction in point of original apprehension between quantity and physical qualities, fails to explain what must be allowed as the specific character of mathematical axioms. Our conviction of their truth cannot be said to depend upon the amount of supporting experience, for increased experience (which is all that Mill secures and secures only for figured magnitude, without psychological reason given) does not make it stronger; and, if they are conceded on being merely stated, which, unless they are held to be analytic propositions, amounts to their being granted upon direct inspection of a particular case, it can be only because the case, so decisive, is made and not found—is constituted or constructed by ourselves, as Kant maintains, with the guarantee for uniformity and adequacy which direct construction alone gives. Still it does not therefore follow that the construction whereby synthesis of subject and predicate is directly made is of the nature described by Kant—due to the activity of the pure *ego*, opposed to the very notion of sensible experience, and absolutely *a priori*. As we have a natural psychological experience of sensations passively received through bodily organs, we also have what is not less a natural psychological experience of motor activity exerted through the muscular system. Only by muscular movements, of which we are conscious in the act of performing them, have we perception of objects as extended and figured, and in itself the activity of the describing and circumscribing movements is as much matter of experience as is the accompanying content of passive sensation. At the same time, the conditions of the active exertion and of the passive affection are profoundly different. While, in objective perception, within the same or similar movements, the content of passive sensation may indefinitely vary beyond any control of ours, it is at all times in our power to describe forms by actual movement with or without a content of sensation, still more by represented or imagined movement. Our knowledge of the physical qualities of objects thus becomes a reproduction of our manifold sensible experience, as this in its variety can alone be reproduced, by way of general concepts; our knowledge of their mathematical attributes is, first

and last, an act of conscious production or construction. It is manifestly so, as movement actual or imaginary, in the case of magnitude or continuous quantity; nor is it otherwise in the case of number or discrete quantity, when the units are objects (points or anything else) standing apart from each other in space. When the units are not objects presented to the senses or represented as coexistent in space, but are mere subjective occurrences succeeding each other in time, the numerical synthesis, doubtless, proceeds differently, but it is still an act of construction, dependent on the power we have of voluntarily determining the flow of subjective consciousness. Thus acting constructively in our experience both of number and form, we, in a manner, *make* the ultimate relations of both to be what for us they must be in all circumstances, and such relations when expressed are truly axiomatic in every sense that has been ascribed to the name.

Beyond the mathematical principles which may be thus accounted for, there are, as was before remarked, no other principles of special science to which the name of axiom is uniformly applied. It may now be understood why the name should be withheld from such a fundamental generalisation as the atomic theory in chemistry, even when we have become so familiar with the facts as to seem to see clearly that the various kinds of matter must combine with each other regularly in definite proportions: the proposition answers to no intuition or direct apprehension. At most could it be called axiomatic in the sense, of course applicable to mathematical principles also, that it is assumed as true in the body of science compacted by means of it. The laws of motion, however, formulated by Newton as principles of general physics, not only were called by him axiomatic in this latter sense, but have been given out by others since his time as propositions intuitively certain; and, though it cannot seriously be pretended that there is the same case for ascribing to them the character of *a priori* truths, there must be some reason why the name of axiom in the full sense has been claimed for them alone by the side of the mathematical principles. The *a priori* character, it is clear, can only in a peculiar sense be claimed for truths which all the genius of the ancients failed to grasp, and which were established in far later times as inductions from actual experiments; Newton, certainly, in calling them axioms, by no means claimed for them aught but an experiential origin. On the other hand, it must be conceded that motion as an experience has in it a character of simplicity, like that belonging to number and form, consisting mainly in a clear apprehension of the circumstances under which the phenomenon varies, while, again, such apprehension is conditioned by the psychological nature of the experience, namely, that it is one depending on activity of our own which we can control, and does not come to us as bare passive affection which we must take as we find it. We do in truth make or constitute motion, as we construct number and space; moving, as we please, without external occasion, and, when apprehending objective movements, following these with conscious motions of our members. Notwithstanding, our proper motions far less adequately correspond to the reality of external motions than do our subjective constructions of space and number answer to the reality of things figured and numbered. With limited store of nervous energy and muscles of confined sweep, we cannot execute at all such continued unvarying movements as occur, at least approximately, in nature; we cannot, by any such combinations of movements as we are able to make, determine beforehand the result of such complex motions as nature in endless variety exhibits; nor, again, can we with any accuracy appreciate the relation between action and reaction by opposing our muscular organs to one another. We must wait long upon experience that comes to us, or rather, in face of the objective complexity presented by nature, sally forth to make varied experiments with moving things, and thereupon generalise, before anything can be determined positively respecting motion. This is precisely what inquirers, until about the time of Galileo, were by no means content to do, and they had accordingly laws of motion which were, indeed, devised *a priori*, but which were not objectively true. Since the time of Galileo true, or at least effective, laws of motion have been established inductively, like all other physical laws; only it is more easy than in the case of the others, which are less simple, to come near to an adequate subjective construction of them, and hence the claim sometimes set up for them to be in fact *a priori* and in the full sense axiomatic.

It remains to inquire in what sense the general principles of all knowledge or principles of certitude may be called, as they often are called, axioms. The laws of Contradiction and of Excluded Middle, noted though not named by Aristotle, together with that formulated as the law of Identity, presupposed as they are in all consistent thinking, have, with a character of widest generality, also a character of extreme simplicity, and may fitly be denominated axioms in the sense of immediate principles. They stand, however, as pure logical principles, apart from all others, being wholly formal, without a shade of material content. There can be no question, therefore, of their certainty being guaranteed by a direct intuition, valid for all cases because fully representative of all; as little does there appear valid ground for calling them, in the proper sense, inductive generalisations from experience. They may rather be held to admit only of the kind of proof that Aristotle calls dialectical: whoever denies them will find that he cannot argue at all or be argued with; he cuts himself off from all part in rational discourse, and is no better, as Aristotle forcibly expresses it, than a plant. The like position of being postulated as the condition of making progress belongs to the very different principle or principles (which may, however, be called logical, in the wider sense) implied in the establishment of truth of fact, more particularly the inductive investigation of nature. Whether expressed in the form of a principle of Sufficient Reason, as by Leibnitz, or, as is now more common, in the form of a principle of Uniformity of Nature, with or without a pendant principle of Causality for the special class of uniformities of succession, some assumption is indispensable for knitting together into general truths the discrete and particular elements of experience. Such postulates must be declared to have an experiential origin rather than to be *a priori* principles, but experience may more truly be said to suggest them than to be their ground or foundation, since they are themselves the ground, express or implied, of all ordered experience. Their case is perhaps best met by pronouncing them hypothetical principles, and as there are no axioms—not even those of mathematics—that are thought of without reference to their proved efficiency as principles leading to definite conclusions, they may be called axiomatic on account of their extreme generality, however little they possess the character of immediacy.

The name axiom, at the end of the inquiry, is thus left undeniably equivocal, and it clearly behoves those who employ it, whether in philosophy or science, always to make plain in what sense it is meant to be taken. Before closing, it is, perhaps, necessary to add why, in dealing with the question of origin, no account has been taken of the doctrine of evolution which has become so prominent in the latest scientific and philosophical speculation. From the point of view of the present article, that doctrine has only an indirect bearing on the inquiry. If the conditions of experience as they are found in the

individual suffice to explain the different assurance with which general assertions are made in different departments in knowledge, there is no need to carry the psychological consideration farther back. The effect of such difference in the conditions of experience may, of course, be accumulated in the life of the race, and the accumulation may go far to determine the psychological history of the individual, but the question, as a rational one, must be decided upon analysis of the conditions as they are. (G. C. R.)

AXMINSTER, a market-town of England, in the county of Devon, 147 miles from London, and 24 from Exeter. It takes its name from the River Axe, on which it stands. The ancient abbey-church, or minster, which adorns the centre of the town, was built by King Athelstan to commemorate a victory over the Danes. The town was formerly distinguished for its production of the best and most costly description of carpets; and it still manufactures broad and narrow cloths, cotton, leather, gloves, tapes, and druggets. Dr Buckland was a native of the town. Population of the parish in 1871, 2861.

AXUM, an ancient city of Abyssinia, 85 miles N.W. of Antalo, still remarkable for its ruins. It was for a long time the capital of a great Shemitic people, who extended their sway over a large part of Abyssinia; and the language spoken there at the time of the introduction of Christianity has continued to be the ecclesiastical language ever since. The chronicles of Abyssinia were preserved in the church, and are frequently referred to as the *Books of Axum*. The most interesting of the monuments still extant are the obelisk and the so-called coronation-room, both constructed of granite, and the latter containing some valuable bilingual inscriptions. In the modern town, which is the capital of the kingdom of Tigré, the weaving of cotton and manufacture of parchment are carried on. (See Salt's *Travels*, and Schimper in *Zeitsch. der Ges. Erdk.*, Berlin, 1869.)

AYAMONTE, a fortified city of Spain, in the province of Huelva, on the left bank of the Guadiana, about 2 miles from its mouth. The harbour is good, but, on account of a bar at its mouth, it is of difficult entrance. The principal employment of the inhabitants is afforded by the fisheries, especially for sardines, tunny, cod, and horse-mackerel; but this branch of industry has suffered by the extension of the general coasting traffic. Silk-weaving is carried on. Ayamonte is said to have had in the 16th century 16,000 inhabitants. Population, 5960.

AYLESBURY, a market-town, parliamentary borough, and railway junction, in the county of Buckingham, 39 miles N.W. of London. It stands on a gentle eminence in the centre of a fertile vale, and consists of several streets and lanes irregularly built, but well paved and lighted. The county-hall, market-house, and county gaol are handsome buildings, as is also the parish church, an ancient structure with a tower rising from the centre. It has a free grammar-school (1611), several other schools and charities, a corn-exchange (1865), three banks, a savings bank, an infirmary (1833), a union workhouse, and places of public worship for Roman Catholics, Methodists, Baptists, Independents, &c. It returns two members to parliament. The assizes and quarter sessions and the elections of members for the county are held here. The inhabitants are principally employed in the manufacture of bonelace and straw-plaiting, besides the rearing of ducks, which are sent in large quantities to the London market at Christmas. A branch canal, six miles in length, connects Aylesbury with the Grand Junction Canal. Population of parliamentary borough in 1871, 28,760.

AYLESFORD, a village of England, in the county of Kent, 3½ miles from Maidstone, and 32 from London. It stands at the base of a hill on the right bank of the Medway, which is here crossed by a stone bridge of six arches. The church stands on an eminence behind the village. At a short distance to the W. was a Carmelite friary, founded in 1240, the remains of which now form a part of the family mansion of the earl of Aylesford. The vicinity exhibits several remains of antiquity, among which is, or rather was, for it is grievously destroyed, a cromlech called Kit's Coity House, about a mile N.E. from the village. This is supposed by Mr Fergusson, in accordance with tradition, to mark the burial-place of Catigern, who was slain here in a battle between the Britons and Saxons in 455 A.D. The tomb of Horsa, who fell in the same battle, is situated at Horsted, about 2 miles to the N. Near Aylesford, too, are other remains, known as the Countless Stones. Population of parish in 1871, 2100.

AYLMER, JOHN, Bishop of London in the reign of Queen Elizabeth, was born in the year 1521 at Aylmer-hall, in the parish of Tilney, in the county of Norfolk. Whilst a boy, he was noticed for his precocity by the marquis of Dorset, afterwards duke of Suffolk, who sent him to the university of Cambridge. He afterwards proceeded to Oxford, where he completed his studies and took his degree in divinity. He was then made chaplain to the duke and tutor to his daughter, the accomplished and unfortunate Lady Jane Grey, whose extraordinary proficiency in the Greek and Latin languages reflects no small honour on her preceptor. His first preferment was to the archdeaconry of Stow, in the diocese of Lincoln, which gave him a seat in the Convocation held in the first year of Queen Mary, where he resolutely opposed the return to Popery, to which the generality of the clergy were inclined. He was soon after obliged to fly his country, and take shelter among the Protestants in Switzerland. While there he wrote a reply to Knox's famous *Blast against the Monstrous Regiment of Women*, under the title of *An Harborowe for Faithfull and Trewe Subjects*, &c. On the accession of Queen Elizabeth he returned to England. In 1562 he obtained the archdeaconry of Lincoln, and was a member of the famous synod of that year, which reformed and settled the doctrine and discipline of the Church of England. In 1576 he was consecrated bishop of London, and while in that position made himself notorious by the harsh manner in which he insisted on the Act of Uniformity. His persecution of the Puritans, and of any clergymen suspected of Puritanical leanings, with the extreme measures he used, made him unpopular even with his own party. He is frequently assailed in the famous *Marprelate Tracts*, and is characterised as *Morrell*, the bad shepherd, in Spenser's *Shepheardes Calendar*. He seems to have been a man of harsh and violent temper, coarse, and avaricious, and with few redeeming qualities. He is said to have been an able scholar, but he has left nothing which could prove this. He died in 1594. (Strype, *Life and Actions of John Aylmer, Bishop of London*.)

AYR, COUNTY OF, or AYRSHIRE, a Scottish county, bounded by Wigtownshire and the stewartry of Kirkcudbright on the S.; by Kirkcudbright, Dumfries, and Lanark on the E.; and by Renfrewshire on the N. On the W. it has a coast-line extending to 70 miles on the Irish Sea and the Firth of Clyde. The county contains 1149 square miles, or 735,262 acres. The middle part, which is the broadest, is about 26 miles across. There are six rivers of some note in Ayrshire—Stinchar, Girvan, Doon, Ayr, Irvine, and Garnock. Of these the Ayr, from which the county and county town take their name, is the largest. It rises at Glenbuck, on the border of Lanarkshire, and, after a course of 33 miles, falls into the Firth of Clyde at the county town. The scenery along its banks from Sorn downwards—passing Catrine, Ballochmyle, Barskim-

ming, Sundrum, Auchencruive, and Craigie—is varied and beautiful. The lesser streams are numerous; and there are many fresh-water lochs, the largest of which is Loch Doon, the source of the river Doon. The southern and eastern parts of the county are hilly, but none of the peaks reaches a height of 2000 feet. In former times the shire was divided into three districts—Carrick, south of the Doon; Kyle, between the Doon and the Irvine; and Cunningham, north of the Irvine. Kyle, again, was divided by the river Ayr into King's Kyle on the south, and Kyle Stewart on the north. The county is now politically divided into south and north Ayrshire. The former comprises Kyle and Carrick, and the latter Cunningham, and each division returns a representative to Parliament. The old divisions, however, are still popularly retained. The greater part of Carrick is hilly, and fit only for sheep-walks. The uplands of Kyle are also extensive, but there is a larger proportion of good low-country land in that district. Cunningham is comparatively level, and has a great extent of rich land, though rather heavy in its character. The scenery is not grand in any part of the county, but much of it is picturesque and beautiful. From many of the heights a rich, undulating, well-wooded country may be seen, with the Bay of Ayr, or the Firth of Clyde beyond, and the lofty peaks of Arran, or the Argyllshire hills, in the distance.

There has been no lack of agricultural enterprise in Ayrshire. With a moist climate, and, generally, a rather heavy soil, draining was necessary for the successful growth of green crops. Up till 1840, or a few years later, a green crop in the rotation was seldom seen, except on porous river-side land, or on the lighter farms of the lower districts. In the early part of the century lime was a powerful auxiliary in the inland districts, but, with repeated applications, it gradually became of little avail. Thorough draining gave the next great impulse to agriculture. Enough had been done to test its efficacy previous to the announcement of Sir Robert Peel's drainage loan, after which it was rapidly extended throughout the county. Green-crop husbandry, and the liberal use of guano and other auxiliary manures, made a wonderful change on the face of the county, and increased immensely the amount of agricultural produce. Early potatoes are now extensively grown in some localities. The farmers on the coast lands of Girvan and West Kilbride are first in the market, and the next supplies come from the friable lands about Ayr and St Quivox. A considerable extent of ground is cleared in June for the Glasgow market; and, in dropping seasons, good crops of turnips follow. At the end of July and the beginning of August, great quantities of potatoes are sent to Newcastle, and to the large towns of Lancashire and the West Riding. The mild climate of the Ayrshire coast in spring is favourable to this kind of cropping, which brings quick returns, and on the whole is profitable. Carrots and mangolds are cultivated more extensively than in any other Scotch county, and, with early sowing and rich manuring, heavy crops are raised. Wheat generally follows green crops in the lower parts of the county, though barley is coming more into use than in former times on light land. The border line for wheat may be drawn at a little over 300 feet; above that height its growth is exceptional. The dairy forms an important department of farm management in Ayrshire. Dunlop cheese was a well-known product of Ayrshire dairies a quarter of a century ago. Part of it was very good; but it was unequal in its general character, and unsaleable in English markets. Dissatisfied with the inferior commercial value of their cheese in comparison with some English varieties, the Ayrshire Agricultural Association brought a Somerset farmer and his wife in 1855 to teach the Cheddar method, and their effort has been most successful. Cheddar cheese of first-rate quality is now made in Ayrshire and Galloway, and the annual cheese show at Kilmarnock is the most important in the kingdom. The cheese may be more thoroughly fine in a few Somerset dairies, but the average quality of Scotch Cheddar is higher than the English. This great change of an industrial art has brought wealth to the county. It is not too much to say that it has added £2 per cow to the annual value of dairy produce, and there are 45,000 cows in Ayrshire.

The manufactures of Ayrshire have attained considerable importance. The cotton works at Catrine are extensive, and have been a long time established. The site was chosen with the view of utilising the water power of the river Ayr, and steam is still merely an auxiliary. At Kilmarnock and Ayr there are extensive engineering establishments, and large carpet works; and other fabrics are manufactured in those towns and at Dalry, Kilbirnie, Beith, and Stewarton. Until the last three or four years, Irvine was a back-going place, but it has received an impulse from the erection of large chemical works. The situation is very suitable for chemical manufactures, as the soil is poor and sandy, and the liquid refuse of chemical works is easily carried into the sea, without causing the nuisance which is inevitable in a large town. The Eglinton Chemical Company are most extensive manufacturers of bichromate of potash—a substance which is used at dyeworks as an oxidising agent; and another company is largely engaged in the alkali trade, and in the extraction of copper from burnt pyrites ore. On the coast, between Irvine and Ardrossan, works have been erected on the sandhills for the manufacture of dynamite, which is now well known as one of the most powerful explosive agents. It is much used for blasting under water, and large quantities of it are sent to America for blowing up the roots of trees in the reclamation of land.

The iron trade of Ayrshire has risen to great importance. The manufacture has long been carried on at Muirkirk, although the iron had to be carted long distances to Ayr and Glasgow before the introduction of railways. Immense fields of ironstone have been opened up within the last quarter of a century; and there are now 33 furnaces in blast within the county, producing about 330,000 tons per annum. The works are all connected with the Glasgow and South-Western Railway. The whole manufacture of iron in Ayrshire is in the hands of three great companies, namely, William Baird & Company, the Dalmellington Iron Company, and Merry & Cunningham. Hæmatite of good quality is raised in Sorn and Muirkirk, and discoveries of it have been made in Carrick. The coal-fields are of great extent, and limestone exists in large quantities. A valuable whetstone quarry is worked at Bridge of Stair on the Ayr.

The old harbours of the county were at Ayr, Irvine, and Saltcoats. The latter is now neglected, and its place is supplied by the more important harbour of Ardrossan. The works at Ardrossan were carried through by the private enterprise of the last two earls of Eglinton. They were begun in the early part of this century, with the expectation of making Ardrossan an important shipping port for Glasgow, in connection with a canal, which, however, was never carried further than from Glasgow to Johnstone. The works were designed by Telford. The pier was finished in 1811, and the docks were completed by the late earl. The harbour of Troon was likewise the work of an enterprising nobleman. It was formed by the late duke of Portland, who connected it with Kilmarnock by a railway, which was among the earliest in the country. Troon has an extensive shipping business, as the outlet for the great coal-fields of the Kilmarnock district. Acts of parlia-

ment have been obtained, which sanction harbour improvements at Irvine and Girvan, and a large wet-dock is in course of formation at Ayr. The dock at Ayr is important, as Ayr is the natural outlet for the great coal-fields up the river, and for the ironworks at Dalmellington, Lugar, and Muirkirk, as well as the fields which are being developed on the railways, called the Ayrshire lines, between Cumnock and the river Doon.

The Glasgow, Kilmarnock, and Ayr Railway was partially opened in 1840, and soon after completed. A connection was made a few years later from the Ayr line at Kilwinning to Ardrossan, and an extension from Kilmarnock to Cumnock, with a branch to Muirkirk. Extensions followed from Cumnock to Dumfries and Carlisle, and from Ayr to Dalmellington, and to Maybole and Girvan; and the Troon Railway was acquired from the duke of Portland, as a connecting link of what is now the Glasgow and South-Western Railway system. Other important branches have been made, and a trunk line is now in course of formation between Girvan and Stranraer, which will give a connection between Glasgow and Ayrshire and the north of Ireland by the shortest sea passage. Ayrshire is thus well supplied with railways.

The antiquities of Ayrshire are not of much note. There are cairns in Galston, Sorn, and other localities; a road, supposed to be a work of the Romans, which extended from Ayr, through Dalrymple and Dalmellington, towards the Solway; camps, attributed to the Norwegians or Danes, on the hills of Knockgeorgan and Dundonald; and the castles of Loch Doon, Turnberry, Dundonald, Portencross, Ardrossan, &c. There are interesting remains of the celebrated abbeys of Kilwinning and Crossraguel; and the ruins of the little church of Alloway, amid the lovely scenery near the birthplace of Burns, have become more famous from their associations than many great works of architectural genius.

The rural population of Ayrshire is decreasing, but the mining population has increased, and the towns are growing. At the last census there were 27,132 inhabited houses, and the population reached 200,745. The county valuation last year amounted to £1,178,183, 5s. 10d., being an increase of more than £50,000 from the previous year. The amount for Kyle was £446,874, 18s. 5d.; for Cunningham, £411,504, 1s. 6d.; for Carrick, £177,168, 10s. 3d.; for the burgh of Ayr, £63,273, 16s. 6d.; for Kilmarnock, £63,202, 19s.; and for Irvine, £16,159, 0s. 2d.

Ayr, the capital of the above county, is situated at the mouth of the river of the same name, and about 40 miles S.S.W. from Glasgow. The spot has probably been inhabited from a remote antiquity. Nothing, however, is known of its history till the close of the 13th century, when it was made a royal residence, and soon afterwards a royal burgh, by William the Lion. The charter conferring upon it the latter privilege has been preserved, of which a fac-simile will be found in vol. i. of the *National Manuscripts of Scotland*. During the wars of Scottish independence the possession of Ayr and its castle was, according to tradition, an object of importance to both the contending parties. In Blind Harry's *Life of Wallace* they are frequently mentioned, and the scene is laid there of one of the patriot's greatest exploits; but the authenticity of many of the minstrel-historian's statements is more than doubtful. On better authority, the records of the burgh, it is known that early in the 16th century Ayr was a place of considerable influence and trade. The liberality of William the Lion had bestowed upon the corporation an extensive grant of lands; while in addition to the well-endowed church of St John's, it had two monasteries, each possessed of a fair revenue. When Scotland was overrun by Oliver Cromwell, Ayr was selected as the site of one of those forts which he built to command the country. This fortification, termed the citadel, enclosed an area of ten or twelve acres, and included within its limits the church of St John's, in which the Scottish Parliament on one occasion met, and confirmed the title of Robert Bruce to the throne. The church was converted into a storehouse, the Protector partly indemnifying the inhabitants for this seizure by liberally contributing towards the erection of a new place of worship, now known as the Old Church. Ayr proper lies on the south bank of the river, and is connected with Newton and Wallacetown on the north by two bridges, the Old and the New, the "Twa Brigs" of Burns. Of late years the town has extended greatly on the Ayr side of the stream. Nearly the whole of Cromwell's Fort is now covered with houses, and to the south, in the direction of the race-course, numerous fine villas have been erected. Ayr possesses several good streets and a number of elegant public and other edifices. The County Buildings, which afford accommodation for the circuit and provincial courts, as well as for the various local authorities, occupy the west side of Wellington Square. Contiguous to these is the jail, a well-regulated establishment, partly used as a penitentiary. The Town's Buildings, near the New Bridge, is a handsome erection, the effect of which is somewhat impaired by the lowness of the site. They contain assembly rooms and a reading-room, and are surmounted by a spire 217 feet high, designed by Hamilton, of Edinburgh, and considered by many the finest in the west of Scotland. All the Edinburgh and Glasgow banks have branches in Ayr, and some of them have built ornamental structures for their accommodation. Besides the old church already mentioned, there is another parish church called the New, and a number of dissenting places of worship, none of them, however, noteworthy on account of their architecture. The Academy, a large building in a convenient position, includes, or has superseded, the Grammar School of the burgh, the existence of which can be traced back as far as the 13th century. A portion of the tower of St John's Church still remains, but, to the regret of the antiquary, has been completely modernised. The "Wallace Tower" is a Gothic structure in High Street, erected on the site of an old building of the same name taken down in 1835. A niche in front is filled by a statue of the Scottish hero by Thom, a self-taught sculptor, who executed in a much more successful manner the statues of Tam o' Shanter and Souter Johnnie, now in the grounds of Burns' Monument. Ayr Hospital is a plain but substantial erection near the Townhead railway station. There are two subscription libraries in the town, and it also supports one weekly and one bi-weekly newspaper. Its religious and charitable societies are numerous. A market is held every Tuesday, and there are five yearly fairs. The Western Meeting takes place in September of every year on Ayr racecourse, a large enclosure in the suburbs, which has been reserved for this purpose for more than a century. Alloway Kirk and Burns' Monument are distant 2½ miles. The principal manufactures of Ayr are leather, carpets, woollen goods, &c.; and fisheries and shipbuilding are also carried on to a small extent. There are several foundries and engineering establishments. Ayr has a general trade of considerable value. Large quantities of timber are imported from Canada and from Norway; coal and iron are the chief exports. The harbour occupies both sides of the river from the New Bridge to the sea, and has been built at a very considerable expense in a most substantial manner. The south pier projects some distance into the sea; on the north side is a large breakwater protecting the entrance, and on the north pier are three lights, two bright and one red from 12 to

35 feet above high water. The depth of water at the bar is about 14 feet at neap and 16 at spring tides. Extensive docks are in the course of formation, which are expected to increase largely the importance of the place as a seaport. Railways converge upon Ayr from the north, east, and south, opening up a connection with all parts of the country. The burgh unites with Irvine, Inveraray, Campbeltown, and Oban in returning a member to Parliament. Previous to 1873, its municipal boundary on the north was the river, but an Act of Parliament was obtained in that year by which this boundary was extended so as to include Newton-on-Ayr and Wallacetown, and made the same as that of the parliamentary burgh. The corporation of Ayr consists of a provost and four bailies, and twelve town councillors. In 1871 the population of the extended burgh was 17,851. Though thus conjoined with Ayr for the parliamentary franchise and municipal government, and forming with it in reality but one town, Newton and Wallacetown were formerly each quite separate. The former is a burgh or barony of very ancient erection. The original charter has been lost; but it is traditionally said to have been granted by King Robert the Bruce in favour of forty-eight of the inhabitants who had distinguished themselves at Bannockburn. Be this as it may, the common property of the burgh is held to be the exclusive property of the freemen, forty-eight in number. The extent of the lots possessed by each varies from six to ten acres, and their value is considerable. Newton has a council, consisting of two bailies, a treasurer, and six councillors, annually elected by the freemen from among their own number; but the powers of the council, though originally extensive, are now very limited. Wallacetown is *quoad civilia* a part of the neighbouring parish of St Quivox. About two miles east of Newton is the village of Prestwick, the headquarters of one of the most flourishing golf clubs in Scotland.

AYRER, Jacob, one of the earliest dramatists of Germany, was born in 1560, probably at Nuremberg,—at least he resided there when a mere boy. His first occupation was keeping an iron-store, which he did with considerable success. After studying law for some time at Bamberg, where he attained a good position as a lawyer, he returned to Nuremberg, and continued to practise there, acquiring the freedom of the city in 1594, and ultimately becoming an imperial notary. He died 26th March 1605. Ayrer's works consist of numerous small poems, and of the series of dramas on which his fame rests. Like other dramas of the time, his productions are, for the most part, spectacular displays, with laboured dialogue, and vary in length from five to twenty-eight acts. The plots are plainly taken from the Latin and Italian tales which supplied material to nearly all the early European dramatists. The chief interest of Ayrer's works for English readers arise from their connection with Shakespeare. Ayrer adopted several of Shakespeare's plots, as well as his method of representing the characters on the stage after life, "and so produced," says his editor, "according to the *new* English manner and art, that all can be personally acted and placed so that it shall seem to the spectators to be really happening." In Ayrer's time the dramatic spirit in England was strong, and good plays and players abounded. Some of the latter took circuits through Germany, and though performing in their native tongue, excited enthusiasm by their vivacity. Ayrer caught this enthusiasm, and adapted several of the English dramas to the German stage. The *Opus Theatricum*, in one folio volume of 1262 pages, was published posthumously in 1618. It contained thirty plays and thirty-six carnival interludes. A second volume to contain forty more, though promised, did not appear. Of the comedies and tragedies of Ayrer, six have been reproduced with an English translation in Cohn's *Shakespeare in Germany*. These contain respectively plots resembling *The Tempest*, *Much Ado about Nothing*, *The Two Gentlemen of Verona*, *Titus Andronicus*, *Romeo and Juliet*, and *Hamlet*. In 1601, a comic prose work by Ayrer was published, giving an account of an *Imaginary Suit of the Devil against Jesus Christ for Destroying Hell*. Some of his plays were published prior to 1585, but these are not now to be had, and even the folio of 1618 is extremely rare. Further information about Ayrer may be gained from Tieck's *Deutsches Theater*, vol. i.; Wolff's *Encyc. der Deutschen Nationalliteratur*, vol. i.; Cohn's *Shakespeare in Germany*; Dr Bell's *Shakespeare's Puck, and his Folklore*; Dr Latham's *Two Dissertations on "Hamlet;"* W. J. Thom's *Three Notelets on Shakespeare*.

AYTON, Sir Robert (1570–1638), a Scottish lyrical poet, the second son of Andrew Ayton of Kinaldie in Fifeshire, was educated at the University of St Andrews, and seems afterwards to have resided for several years in France, where he gained considerable reputation as a poet and scholar. On the accession of James VI. in 1603, Ayton published a very elegant Latin panegyric, which at once brought him into notice and favour at court. He was knighted by the king, and held various important offices, particularly that of private secretary to the queen. He was of an exceedingly amiable disposition, and was much beloved by his contemporaries; even Ben Jonson, who criticised all other poets so severely, seems to have made an exception in his favour, for he told Drummond that Sir Robert loved him dearly. Ayton's extant works consist of some Latin poems, and of a few pieces in the English dialect, which are distinguished by smoothness of rhythm and delicacy of fancy. His best ode, *Inconstancy Reproved*, beginning, "I do confess thou'rt smooth and fair," may take rank with the finest pieces of Herrick or Suckling, while a few others are but little inferior. His poems have been collected and published by C. Rogers (Edin. 1844).

AYTOUN, William Edmonstoune, a Scottish poet, humorist, and miscellaneous writer, was born at Edinburgh, 21st June 1813. He was the only son of Roger Aytoun, a writer to the Signet, and the family was of the same stock as Sir Robert Ayton noticed above. From his mother, a woman of marked originality of character and considerable culture, he derived his distinctive qualities, his early tastes in literature, and his political sympathies, his love for ballad poetry, and his admiration for the Stuarts. At the age of eleven he was sent to the Edinburgh Academy, whence he passed in due time to the University, studied the classics under Professors Pillans and Dunbar, and attended the course of Professor John Wilson on Moral Philosophy. In 1833 he spent a few months in London for the purpose of studying the law; but in September of that year he went to study German at Aschaffenburg, where he remained till April 1834. He then resumed his legal pursuits in his father's chambers, was admitted a writer to the Signet in 1835, and five years later was called to the Scottish bar. But, by his own confession, though he "followed the law, he never could overtake it." He disliked his profession, and allowed his literary tastes to predominate. His first publication—a volume entitled *Poland, Homer, and other Poems*, in which he gave expression to his eager interest in the state of Poland—appeared in 1832. While in Germany he made a translation in blank verse of the first part of *Faust*; but, forestalled by other translations, it was never published. In 1836 he made his earliest contributions to *Blackwood's Magazine*, in translations from Uhland; and from 1839 till his death he remained on the staff of *Blackwood*. About 1841 he became acquainted with Mr Theo-

dore Martin, and in association with him wrote a series of light humorous papers on the tastes and follies of the day, in which were interspersed the verses which afterwards became popular as the *Bon Gaultier Ballads*. The work on which his reputation as a poet chiefly rests is the *Lays of the Scottish Cavaliers*. The first of these appeared in *Blackwood's Magazine* in April 1843, and the whole were published in a collected edition in 1848. They became very popular, and have passed through nineteen editions, the last of which has spirited and beautiful illustrations by Sir J. Noel Paton and W. H. Paton. Meanwhile, he obtained, in 1845, the chair of Rhetoric and Belles Lettres at Edinburgh University, which he filled honourably and successfully till 1864. He devoted himself conscientiously to the duties of the office, and his pupils increased in number from 30 to 150. In 1849 he married the youngest daughter of Professor John Wilson (Christopher North), whose death, in 1859, was the great calamity of his life. His services in support of the Tory party, especially during the Anti-Corn-Law struggle, received official recognition in his appointment (1852) as sheriff of Orkney and Zetland. In 1854 appeared *Firmilian, a Spasmodic Tragedy*, in which he attacked and parodied the writings of Bailey, Sydney Dobell, and Alexander Smith; and two years later he published his *Bothwell, a Poem*. Among his other literary works are a *Collection of the Ballads of Scotland*, a translation of the *Poems and Ballads of Goethe*, executed in co-operation with his friend Theodore Martin, a small volume on the *Life and Times of Richard I.*, written for the *Family Library*, and a novel entitled *Norman Sinclair*, many of the details in which are taken from incidents in his own experience. In 1860 Aytoun was elected honorary president of the Associated Societies of Edinburgh University. The death of his mother took place in November 1861, and his own health was failing. In December 1863 he married Miss Kinnear, and health and happiness for a time revived; but his malady recurred, and he died at Blackhills, near Elgin, 4th August 1865. His remains were interred at Edinburgh. A memoir of Aytoun by Theodore Martin, with an appendix containing some of his prose essays, was published in 1867. (W. L. R. C.)

AZAIS, Pierre Hyacinthe, a brilliant French writer on philosophy, was born at Sorrèze in 1766, and died at Paris in 1845. He was educated at the college in his native town; and at the age of 17 joined a religious body with the view of afterwards entering the church. He remained only a year in this society, and then accepted an appointment as teacher in the college at Tarbes. The duties of this office proved most uncongenial to him, and he gladly entered the service of the bishop of Oléron, to whom he acted as secretary. With this, too, he quickly became dissatisfied, either on account of the bishop's reiterated desire that he should take orders, or from the many petty annoyances incident to his post. He withdrew to the little village of Villemagne, near Beziers, where he supported himself by performing the duties of organist in the church. He afterwards acted as tutor to the Count de Bose's sons, with whom he remained till the outbreak of the Revolution. Azais, at first an ardent admirer of that great movement, was struck with dismay at the atrocities that were perpetrated, and published a vehement pamphlet on the subject. He was denounced, and had to seek safety in flight. For eighteen months he found refuge in the hospital of the Sisters of Charity at Tarbes; and it was not till 1806 that he was able to settle in Paris. There, three years later, he published his treatise *Des Compensations dans les Destinées Humaines*, in which he sought to show that happiness and misery were fairly balanced in this world, and that consequently it was the duty of citizens to submit quietly to a fixed government. This doctrine was not displeasing to Napoleon, who made its author professor at St Cyr. After the removal of that college, he obtained, in 1811, the post of inspector of the public library at Avignon, and from 1812 to 1815 he held a similar office at Nancy. His preference for the Bonaparte dynasty naturally operated in his disfavour at the Restoration; but after suffering considerable privation for some years, he obtained a government pension, which placed him beyond the reach of want. He employed the remaining years of his life in oral and published expositions of his system of philosophy.

According to Azais, the whole of existence, the universe, whose cause is God, may be regarded as the product of two factors, Matter and Force. Matter in its primitive state consists of homogeneous elements or atoms. All force is in its nature expansive, and is, therefore, subject to one supreme law, that of equilibrium, or equivalence of action and reaction; for evidently expansive force emanating from each body is repressive force acting on all other bodies. The whole of the phenomena of the universe are successive stages in the development caused by the action of this one force under its one law on the primitive atoms; and in tracing this development we must group facts into three distinct orders,—first, the physical; second, the physiological; third, the intellectual, moral, and political. In the sphere of physical phenomena, distinct development can be traced from the simplest mechanical motion up through the more complex forces of light, heat, and electricity to the power of magnetic attraction, by means of which the second great order of facts is produced out of the first. For magnetic force acting on elastic bodies, which as reactive have potential life, creates the primitive living globule, which is shaped like a tube open at both ends. From this first vital element a gradual ascent can be traced, culminating in man, who is differentiated from the other animals by the possession of intellect, or consciousness of the ideas with which external things impress him. These ideas, however, are in themselves corporeal; what is immaterial in man, or his soul, is the expansive force inherent in him. Moral and political phenomena are the results of two primitive instincts, progress, and self-conservation, corresponding to the two forces, expansion and repression. From the reciprocal relations of these instincts may be deduced the necessary conditions of social and political life. The ultimate goal of humanity is the perfect fulfilment of the law of equilibrium, the establishment of universal harmony. When that is accomplished, the destiny of man has been achieved, and he will vanish from this earth. Such a consummation may be looked for in about 7000 years. During an additional period of 5000 years the great cosmical forces will be gradually tending towards the establishment of complete equilibrium; and, when this is attained, the present system of things is at an end.

The chief works of Azais, besides the *Compensations*, are—*Système Universel*, 8 vols. 1812; *Du Sort de l'homme*, 3 vols. 1820; *Cours de Philosophie*, 8 vols. 1824; *Explication Universelle*, 3 vols. 1826–8; *Jeunesse, Maturité, Religion, Philosophie*, 1837; *De la Phrenologie, du Magnetisme, et de la Folie*, 1843.

AZARA, Don Felix de, a Spanish naturalist, was born 18th May 1746, and died in 1811. He studied first at the university of Huesca, and afterwards at the military academy of Barcelona. In 1764 he entered the army as a cadet, and in 1767 obtained an ensigncy in the engineer corps. In 1781 he was appointed, with the rank of lieutenant-colonel of engineers and captain in the navy, on a commission to lay down the line of demarcation between the Spanish and the Portuguese territories in South America. There he spent many years, observing and collecting specimens of the various interesting objects of

natural history that abound in those wide and little-known regions. In 1801 he obtained leave to return to Spain, and after a short residence at Paris, was appointed a member of the *Junta de fortificaciones y defensa de Ambos Indias*, a public board, in which chiefly was centred the home government of the Spanish colonies. His principal work is his *Travels in South America from* 1781 *to* 1801; published in French from the author's MS., by C. A. Walckenaer, with atlas and plates, 4 vols. 8vo, Paris, 1809. It contains a valuable account of the discovery, conquest, and civil and natural history of Paraguay and Rio de la Plata; and embodies his former contributions to the zoology of these countries, which had appeared in a French translation at Paris in 1801. The work is enriched with the notes of Walckenaer and Cuvier, and a notice of the author by the former. An English translation of part of Azara's work on the *Natural History of Paraguay* appeared at Edinburgh in 1838.

AZARA, Don Jose Nicholas d', the elder brother of the naturalist, born in 1731, was appointed in 1765 Spanish agent and procurator-general, and in 1785, ambassador at Rome. During his long residence there he distinguished himself as a collector of Italian antiquities and as a patron of art. He was also an able and active diplomatist, took a leading share in the difficult and hazardous task of the expulsion of the Jesuits from Spain, and was instrumental in securing the election of Pius VI. He withdrew to Florence when the French took possession of Rome in 1798. He was afterwards Spanish ambassador at Paris; was three times deprived of, and restored to his office; and was finally preparing to return to his antiquarian studies in Italy when he was seized with a fatal illness, and died at Paris in January 1804.

AZEGLIO, Massimo Taparelli, Marquis d', an eminent Italian author and statesman, was born in October 1798, at Turin. He was descended from an ancient and noble family of Piedmont, and was the son of a military officer, who, when the subject of this notice was in his fifteenth year, was appointed ambassador to Rome. The boy went with him, and, being thus introduced to the magnificent works of art for which the Eternal City is famous, contracted a love for painting as well as for music. He desired to become a painter, and, although his studies were for a time interrupted by his receiving a commission in a Piedmontese cavalry regiment, and by a subsequent illness, brought on by the severity of his scientific investigations and resulting in his quitting the service, he eventually returned to Rome, and, with some difficulty, obtained his father's permission to devote himself to art. He remained at the Papal capital eight years, and acquired great skill and some fame as a landscape-painter. At the close of that period events directed his mind into other channels. His father died in 1830, and the younger Azeglio then removed to Milan, where he became acquainted with Alessandro Manzoni, the poet and novelist, whose daughter he married. In this way his thoughts were turned towards literature and politics. At that time, Italy was profoundly agitated by the views of the national and liberal party. The country was divided into several distinct states, of which the greater number, even of those that were nominally independent, were under the influence of Austria. Lombardy and Venetia formed parts of the Austrian dominions. The petty monarchies of the north were little better than vassals to the house of Hapsburg; the Papacy, in the centre, was opposed to all national aspirations; and the kingdom of the Two Sicilies, in the south, was a despotism, which for cruelty and mental darkness could not have been exceeded in Asia itself. The French revolution of July 1830 gave additional force to the movements of the Italian liberal party, and the young men of the day threw themselves with fervour into the crusade against old abuses and foreign domination. Mazzini was just beginning his career as an agitator, and the whole air was surcharged with revolutionary enthusiasm. This was especially the case in the north of Italy, where Massimo d'Azeglio was now settled. Art was abandoned by him for literature, and literature was practised with a view to stimulating the sense of national independence and unity. In 1833, M. d'Azeglio published a novel called *Ettore Fieramosca*, which was followed in 1841 by another, entitled *Niccolo di Lapi*. Both had a political tendency, and, between the two dates at which they appeared, M. d'Azeglio visited various parts of Italy, diffusing those liberal principles which he saw were the only hope of the future. His views, however, were very different from those of the republican party. He was a constitutional monarchist, and strongly opposed to the insurrections and secret conspiracies which Mazzini and others so frequently fostered at that time, and which always resulted in failure and renewed oppression. His treatise *Degli Ultimi Casi di Romagna* (Of the Last Events in the Romagna), published in 1846, before the death of Pope Gregory XVI., was at once a satire on the Papal Government, a denunciation of the republican attempts at insurrection, and an exhortation to the Italian princes to adopt a national policy. M. d'Azeglio returned to Rome in 1846, after the death of Pope Gregory, in June, and, it is thought, had considerable influence in persuading the new Pope (Pius IX.) to conduct his government in accordance with liberal principles. He supported measures relating to the freedom of the press, the reform of the Papacy, and the emancipation of the Jews. In 1848 he accompanied the Papal army of observation sent from Rome to watch the insurgent forces in Lombardy and Venetia, which had temporarily discomfited the Austrians, and were being supported by Charles Albert, king of Sardinia. General Durando, who had the command of the Papal army, actively assisted the rebels, in defiance, it is said, of his instructions; and Azeglio was severely wounded in the leg at the battle of Vicenza, where he commanded a legion. In the same year (1848), he published a work on the *Austrian Assassinations in Lombardy;* and on the opening of the first Sardinian parliament he was chosen a member of the chamber of deputies. After the crushing defeat of the Sardinians at Novara, March 23, 1849,—a defeat which brought the second of the two brief wars with Austria to a disastrous close,—d'Azeglio was made president of the cabinet by Victor Emmanuel, in whose favour his father, Charles Albert, had just resigned. In this position the marquis used his high powers with great advantage to the progress and consolidation of the Sardinian kingdom. His occupation of the office lasted from the 11th of May 1849 to the 20th of October 1852, when he was replaced by Count Cavour. At the termination of the war of 1859, when a large portion of the States of the Church shook off the dominion of the Pope, and declared for annexation to the kingdom of Northern Italy, Azeglio was appointed general and commissioner-extraordinary, purely military, for the Roman States—a temporary office, which he administered in a conciliatory and sagacious spirit. He died on the 11th of January 1866, leaving a reputation for probity and wisdom, which his countrymen will not forget to cherish. His writings, chiefly of a polemical character, were numerous. In addition to those already mentioned, the most noteworthy was a work on *The Court of Rome and the Gospels*, of which an English translation, with a preface by Dr Layard, appeared in 1859. A volume of personal recollections was issued, in 1867, after M. d'Azeglio's death.

AZERBIJAN (so called, according to Sir William Ouseley, from a fire-temple; *azer*, fire, and *baijan*, a keeper), a pro-

vince of Persia, corresponding to the ancient Atropatene. It is separated from a division of the Russian Empire on the N. by the River Araxes, and from Irak on the S. by the Kizil-Uzen, or Golden Stream, while it has the Caspian Sea and Ghilan on the E., and Asiatic Turkey on the W. Its area is estimated at 25,280 square miles. The country is superior in fertility to the southern provinces of Persia. It differs entirely from the provinces of Fars and Irak, as it consists of a regular succession of undulating eminences, partially cultivated, and opening into extensive plains such as Anjan, Tabreez, and Urumiyah or Van. Near the centre of the province the mountains of Sahend or Serhund rise in an accumulated mass to the height of 9000 feet above the sea. The highest point, Mount Sevellan, towards its eastern frontier, attains a height of about 12,000 feet according to some authorities, but according to Khanikoff, it is 15,400; and the Talish Mountains, which run from N. to S. parallel to, and at no great distance from, the Caspian, have an altitude of 7000 feet. Except the boundary rivers already mentioned, there are none of any great extent; but these both receive a number of tributaries from the province, and several streams of considerable volume, such as the Jughutu, the Agi, and the Shar, belong to the basin of the Lake Urumiyah. This lake is about 300 miles in circumference, and 4200 feet above the sea. Its waters are more intensely salt than the sea, and it is "supposed to contain no living creature except a kind of polype;" but it is the resort of great flocks of the flamingo. The country to the N. and W., namely, the districts of Urumiyah and Selmart, is the most picturesque and prosperous part of Azerbijan; yet even here the traveller from the more civilised regions of Europe laments the want of enterprise among the inhabitants. Azerbijan is on the whole, however, reckoned one of the most productive provinces of Persia, and the villages have a more pleasing appearance than those of Irak. The orchards and gardens, in which they are for the most part embosomed, yield delicious fruits of almost every description, which are dried in large quantities. Provisions are cheap and abundant, and wine is made in considerable quantities. There is throughout the district a lack of forests and of timber trees. Lead, copper, saltpetre, sulphur, and coal are found within the confines of Azerbijan; also a kind of beautiful transparent marble or jasper, which takes the highest polish, and is used in the buildings of Tabreez, Shiraz, and Ispahan, under the name of Tabreez or Belghami marble. There are exports of silk and cotton, textile fabrics, leather, hides and lambskins, dry-fruits, sugar, drugs, tobacco, and wax, &c., the total value in 1870, a year of great trade depression, being £422,632. In the same year the imports amounted to £1,094,717. The chief towns are Tabreez, Urumiyah (the supposed birthplace of Zoroaster), Ardebil, Khoee, Maragha, Dilman, Abbasabad, Mehrand, Siral, and Souj-Bolak. The climate is healthful—in summer and autumn hot, but cold in winter. The cold is severely felt by the lower orders, owing to the want of fuel, for which there is no substitute except dried cow-dung, mixed with straw. The spring is temperate and delightful in the plains, but on the mountains snow lies eight months in the year; and hail-storms are so violent as frequently to destroy the cattle in the fields. The best soils yield from fifty to sixty fold when abundantly irrigated; and supplies of water for this purpose are drawn from the many small rivers by which the province is intersected. Oxen are generally used to draw the plough. The population is of a very varied character, comprising Kurds, Armenians, Syrians, Tatars, Persians proper, and other tribes or nationalities, and is roughly estimated at 2,000,000. The Persian army is largely composed of natives of Azerbijan, who make excellent soldiers; they are subject to compulsory enlistment. The province is under the government of the heir-apparent to the Persian throne. (Kinneir's *Geographical Memoir of the Persian Empire*, 1813; Fraser's *Travels and Adventures in the Persian Provinces on the Caspian Sea*; Rawlinson's "Tabriz to Takhti Suleiman," in *Jour. of Roy. Geog. Soc.*, 1840; Chesney's *Euphrates and Tigris Expedition*, 1850; Abbott's "Memorandum" in *Proc. of Roy. Geog. Soc.*, 1864.)

AZIMGARH, a district and city in the Benares division of British India, and under the jurisdiction of the Lieutenant-Governor of the North-Western provinces, lies between 25° 38′ 3″ and 26° 24′ 45″ N. lat., and 82° 44′ 15″ and 84° 10′ 45″ E. long. It is bounded on the N. by the river Ghagrá, separating it from Gorakhpur district; on the E. by Gházípur district and the river Ganges; on the S. by the districts of Jaunpur and Gházípur; and on the W. by Jaunpur and the Oudh district of Faizábád. Its area in 1872 was returned at 2494 square miles, of which 1268 square miles are under cultivation, 344 square miles are cultivable waste, and the remaining 882 square miles are barren and uncultivable. The population of the district in 1865 was 1,385,872 souls, of whom 1,184,689 were Hindus, and 201,183 Mahometans. The pressure of the population on the soil averaged 555 per square mile. The census of 1872 discloses a population of 1,531,410, of whom 1,333,805 were Hindus, 197,581 Mahometans, and 24 Christians and others; the pressure of the population on the land being 614 per square mile. The portion of the district lying along the banks of the Ghagrá is a low-lying tract, varying considerably in width; south of this, however, the ground takes a slight rise. The slope of the land is from north-west to south-east, but the general drainage is very inadequate. Roughly speaking, the district consists of a series of parallel ridges, whose summits are depressed into beds or hollows, along which the rivers flow; while between the ridges are low-lying rice lands, interspersed with numerous natural reservoirs. The principal streams are the Tons, Sarjú, Khúrd, Kunwar, Majhor, Mangái, Udantí or Aurá, and the Bhansái. The chief lines of road traffic are the following:—(1.) From Gorakhpur to Gházípur, running north and south; (2.) from Gorakhpur to Azímgarh town, in a north-easterly and south-westerly direction, and continued thence to Jaunpur cantonment; (3.) from Gházípur to Azímgarh, and thence on to Faizábád in Oudh; (4.) from Gházípur to Lucknow. The soil is fertile and very highly cultivated, bearing magnificent crops of rice, sugar-cane, and indigo. The principal industries of the district are cotton and silk manufactures, the total value of which in 1872 amounted to £109,081. The settlement of the land revenue in 702 estates or mahals is fixed and permanent; in the remaining 3284 estates a settlement was made by Mr. Thomason in 1836 for thirty years, and is now (1873) undergoing revision. The total revenue of the district from all sources amounted in 1870-71 to £187,464; the expenditure in the same year being £172,550. Six towns are returned by the census of 1872 as containing a population of upwards of 5000 inhabitants—viz., Azímgarh (the capital of the district), population 15,893; Máu-Náth Bhanjan, 13,765; Mubárakpur, 12,068; Sikandarpur, 5239; Dubarí, 5014; and Pur, 5213. The municipalities are as follows:—Azímgarh city: the municipal income, which is derived from octroi, amounted in 1872 to £1233, 2s., the average incidence of taxation being 1s. 6½d. per head of the population. Máu-Náth Bhanjan, municipal income £125, 8s.; Mubárakpur, £112, 16s.; and Sikandarpur, £48. The cost of the municipal police of these three towns is levied by means of a direct cess on house occupiers. The total number of schools in Azímgarh district in 1871-72 was 286, attended

by 4271 Hindu and 3813 Mahometan pupils. The force necessary for the protection of person and property in 1871-72 consisted of 673 regular police, equal to 1 man to every 3·70 square miles of area, or 1 to every 2275 inhabitants; besides a village watch or rural police force consisting of 2538 men, equal to 1 watchman to every 0·98 square miles, or 1 to every 603 inhabitants.

Azimgarh City, the principal place in the district of the same name, is situated on the river Tons, in 26° 0′ N. lat., and 83° 14′ E. long. The city is said to have been founded about 1620 by a powerful landholder named Azím Khán, who owned large estates in this part of the country. For municipal income and population, see above.

AZO, a distinguished professor of civil law in the university of Bologna, and a native of that city. He was the pupil of Joannes Bassianus, who taught at Bologna towards the end of the 12th century, and who was the author of the famous *Arbor Actionum.* Azo, whose name is sometimes written Azzo and Azzolenus, and who is sometimes described as Azo Soldanus, from the surname of his father, occupied a very important position amongst the gloss-writers, and his *Readings* (*Lectura*) *on the Code*, which were collected by his pupil, Alexander de Sancto Ægidio, are considered by Savigny, a most competent judge, to be the most valuable of the works of that school which have come down to us.

AZOFF, or Asov (in Turkish, *Asak*), a town on the left bank of the southern arm of the Don, about 20 miles from its mouth. Its identification with the ancient Tanais and the mediæval Tana seems erroneous; but it was long a place of great importance both as a military and commercial position. Peter the Great obtained possession of it after a protracted siege in 1696, and did a great deal for the security and prosperity of the town. At the peace of 1711, however, he had to restore it to the Turks; and it was not till 1774 that it was finally united to the Russian empire. Since then it has greatly declined, owing to the silting up of its harbour and the competition of the city of Taganrog. Its population, principally engaged in the fisheries, numbers, according to Russian statistics, 16,791.

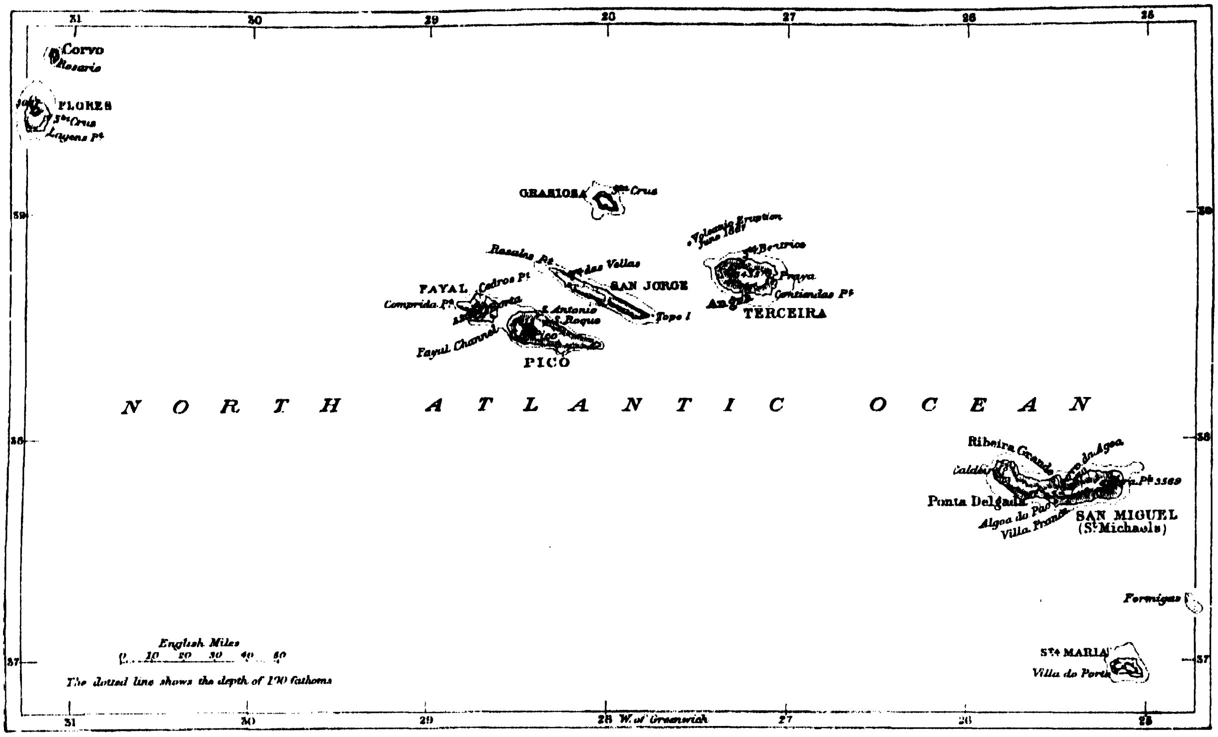
AZOFF, The Sea of, an inland sea of Southern Europe, communicating with the Black Sea by the Strait of Yenikale, the ancient *Bosphorus Cimmerius.* To the Romans it was known as the *Palus Mœotis*, from the name of the neighbouring people, who called it in their native language *Temarenda*, or Mother of Waters. Possibly to account for the outward current into the Black Sea, it was long supposed to possess direct communication with the Northern Ocean, and, when it was discovered that there was no visible channel, recourse was had to a "secret sluice;" there being, it was thought, but a comparatively narrow isthmus to be crossed. In some prehistoric time, according to Pallas and Murchison, a connection with the Caspian Sea seems to have existed; but no great change has taken place in regard to the character or relations of the Sea of Azoff since our earliest records. It lies between 45° 20′ and 47° 18′ N. lat., and between 35° and 39° E. long., its length from S.W. to N.E. being about 235 miles, and its greatest breadth 110. It is for the most part comparatively shallow; the deepest portion forming as it were a prolongation of the bed of the Don, its largest and, indeed, its only very important tributary. Near the mouth of that river the depth varies from 3 to 10 feet, and the greatest depth does not exceed 44 feet. Fierce and continuous winds from the E. prevail during July and August, and in the later part of the year those from the N.E. and S.E. are not unusual. A great variety of currents are thus produced, and the relative depths of the different parts of the sea are greatly modified. From December to March the whole surface is generally frozen. The water is for the most part comparatively fresh, but differs considerably in this respect according to locality and current. Fish are so abundant that the Turks use the name *Balük-Denis*, or Fish-Sea. To the W., separated from the main basin by the long, narrow spit of Arabat, lies the remarkable series of lagunes and marshes known as the Sivash, or Putrid Sea. Here the water is intensely salt, and at the same time swarms with life. The Sea of Azoff is of great importance to Russian commerce, and a number of flourishing cities have grown up along its shores. Of these the most important are Taganrog, Berdiansk, Mariupol, and Yenikale. Unfortunately, there is a lack of safe and commodious harbours and roads.

AZORES, The, or Western Islands, are situated in the Atlantic Ocean, and extend in an oblique line from N.W. to S.E., between 36° 55′ and 39° 55′ N. lat., and between 25° and 31° 16′ W. long. They are generally considered as pertaining to Europe, though separated by a distance of 800 miles from the coast of Portugal. They are divided into three distinct groups: the south-eastern consisting of Saõ-Miguel, or St Michael's, and Sta Maria; the central and largest, of Fayal, Pico, Saõ Jorge, Terceira, and Graciosa; and the north-western, of Flores and Corvo.

It does not appear that the ancient Greeks and Romans had any knowledge of the Azores, but from the number of Carthaginian coins discovered at Corvo it has been supposed that the islands must have been visited by that adventurous people. The Arabian geographers, Edrisi in the 12th century, and Ibn-al-Wardi in the 14th, describe, after the Canaries, nine other islands in the Western Ocean, which are in all probability the Azores. This identification is supported by various considerations. The number of islands is the same; the climate under which they are placed by the Arabians makes them north of the Canaries; and special mention is made of the hawks or buzzards, which were sufficiently numerous at a later period to give rise to the present name (Port. *Açor*, a hawk). The Arabian writers represent them as having been populous, and as having contained cities of some magnitude; but they state that the inhabitants had been greatly reduced by intestine warfare. The Azores are first found distinctly marked in a map of 1351, the southern group being named the Goat Islands (*Cabreras*); the middle group, the Wind or Dove Islands (*De Ventura sive de Columbis*); and the western, the Brazil Island (*De Brazi*)—the word Brazil at that time being employed for any red dye-stuff. In a Catalan map of the year 1375 the island of Corvo is found as *Corvi Marini*, and Flores as *Li Conigi*; while Saõ Jorge is already designated San Zorze. It has been conjectured that the discoverers were Genoese, but of this there is not sufficient evidence. It is plain, however, that the so-called Flemish discovery by Van der Berg is only worthy of the name in a very secondary sense. According to the usual account, he was driven on the islands in 1432, and the news excited considerable interest at the court of Lisbon. The navigator, Gonzalo Velho Cabral—not to be confounded with his greater namesake, Pedro Alvarez Cabral—was sent to prosecute the discovery. Another version relates that Don Henry of Portugal had in his possession a map in which the islands were laid down, and that he sent out Cabral through confidence in its accuracy. The map had been presented to him by his brother, Don Pedro, who had travelled as far as Babylon. Be this as it may, Cabral reached the island, which he named Santa Maria, in 1432, and in 1444 took possession of St Michael's. The other islands were all discovered by 1457. Colonisation had meanwhile been going on prosperously; and in 1466 the Azores were presented by Alphonso V. to his aunt, Isabella, the duchess of Burgundy. An influx of Flemish settlers followed, and the islands became known for a time as the

Flemish Islands. From 1580 to 1640 they were subject to Spain like the rest of the Portuguese kingdom, of which they now form a province. At that time the Azores were the grand rendezvous for the fleets on their voyage home from the Indies; and hence they became a theatre of that maritime warfare which was carried on by the English under Queen Elizabeth against the Peninsular powers. The connection with England has long since been of a more peaceful description; no other country affording such a ready market for Azorean productions.

The islands are now divided into three administrative districts, which take their names from the chief towns of



Map of the Azores or Western Islands.

Angra in Terceira, Horta in Fayal, and Ponta-Delgada in St Michael's—the first of the three being also the capital of the islands. The most of the inhabitants are of Portuguese origin, but there is a mixture not only of Flemish but Moorish blood. Negroes, Mulattoes, English, Scotch, and Irish immigrants are present in considerable numbers, especially in San Miguel and Fayal. Education is in a very backward state, the great proportion of the lower classes being unable to read or write. Progress, however, is being made in this as well as other respects.

Under the active administration of Pombal, considerable efforts were made for the improvement of the Azores, but the stupid and bigoted Government which followed rather tended to destroy these benefits, and to create a retrograde course. Towards the beginning of the present century, the possession of the islands was contested by the claimants for the crown of Portugal. The adherents of the constitution, who supported against Miguel the rights of Maria da Gloria, obtained possession of Terceira in 1829, where they succeeded in maintaining themselves, and after various struggles, Queen Maria's authority was established over all the islands. She resided at Angra from 1830 to 1833.

The aspect of all the islands is very similar in general characteristics, presenting an elevated and undulating outline, with little or no table-land, and rising into peaks, of which the lowest (that of Sta Maria) is 1889 feet, and the highest (that of Pico) 7613 feet above the level of the sea. Their lines of sea-coast are, with few exceptions, high and precipitous, with bases of accumulated masses of fallen rock, in which open bays, or scarcely more enclosed inlets, form the harbours of the trading towns. The volcanic character of the whole archipelago is very obvious, and has been abundantly confirmed by the numerous earthquakes and eruptions which have taken place since its discovery. Hitherto the western group of Flores and Corvo has been quite exempt, Graciosa has been equally undisturbed, and Fayal has only suffered from one eruption, in 1672. The centre of activity has for the most part been St Michael's, while the neighbouring island of Santa Maria has altogether escaped. In 1444–45 there was a great eruption at St Michael's, of which, however, the accounts that have been preserved exaggerate the importance. In 1522 the town of Villa Franca, at that time the capital of the island, was buried, with all its 6000 inhabitants, during a violent convulsion. In 1572 an eruption took place in the island of Pico; in 1580 St George was the scene of numerous outbursts; and in 1614 a little town in Terceira was destroyed. In 1630, 1652, 1656, 1755, 1852, &c., St Michael has been visited with successive eruptions and earthquakes, several of them of great violence. On various occasions, as in 1638, 1720, 1811, and 1867, subterranean eruptions have taken place, which have sometimes been accompanied by the appearance of temporary islands. Of these the most remarkable was thrown up in June 1811, about half a league from the western extremity of St Michael's. It was called Sabrina by the commander of the British man-of-war of that name, who witnessed the phenomenon. Details will be found in a valuable chapter of Hartung's *Die Azoren*, p. 99, and in the 23d vol. of the *Philosophical Transactions*.

The climate is particularly temperate and equable, the extremes of sensible heat and cold being, however, increased by the humidity of the atmosphere. This is so great that paper-hangings will not adhere to the walls, and the veneering of furniture strips off. The range of the thermometer is from 45° Fahr., the lowest known extreme, or 48°, the

ordinary lowest extreme of January, to 82°, the ordinary, or 86°, the highest known extreme of July, near the level of the sea. Between these two points (both taken in the shade) there is from month to month a pretty regular gradation of increase or decrease, amounting to somewhat less than four degrees (*Geographical Journal*, vol. xv.). In winter the prevailing winds are from the north-west, west, and south; while in summer the most frequent are the north, north-east, and east. The weather is often extremely stormy, and the winds from the west and south-west render the navigation of the coasts very dangerous.

The general character of the flora is decidedly European, no fewer than 400 out of the 478 species generally considered as indigenous belonging likewise to that continent, while only four are found in America, and forty are peculiar to the archipelago. Vegetation in most of the islands is remarkably rich, especially in grasses, mosses, and ferns, heath, juniper, and a variety of shrubs. Of tall-growing trees there was, till the present century, an almost total lack; but through the exertions of José de Canto and others the Bordeaux pine, the European poplar, the African palm-tree, the Australian eucalyptus, the chestnut, the tulip-tree, the elm, the oak, and many others, have been successfully introduced into one or more of the islands. The orange, the apricot, the banana, the lemon, the citron, the Japanese medlar, and the pomegranate, are the common fruits, and various other varieties are more or less cultivated. At one time much attention was given to the growing of the sugar-cane, but it has now for the most part been abandoned. The culture of woad introduced in the 16th century also belongs to the past. A kind of fern (*Dicksonia culcita*), called by the natives *cabellinho*, and common throughout the archipelago, furnishes a silky material for the stuffing of mattresses, which forms an article of export to Brazil and Portugal.

The mammalia of the Azores are limited to the rabbit, weasel, ferret, rat (brown and black), mouse, and bat, in addition to domestic animals. Among the fish caught off the coast may be mentioned the mullet, the tunny, the bonito. The numbers of birds are so remarkable that in St Michael's, where a reward is given for the destruction of the blackbird, the bullfinch, the redbreast, the chaffinch, and the canary, the sum paid annually represents a death-list of 420,000. The game includes the woodcock, red partridge (introduced in the 16th century), quail, and snipe.

St Michael's.

St Michael's, the largest and most populous of the islands, has an area of 224 square miles, and 105,404 inhabitants. The east end rises from a bluff cliff, from 1200 to 1400 feet high, to a lofty inland peak, whence a central range, varying in height from 2000 to 2500 feet, runs to the westward, terminating in the Serra da Agoa de Paõ, 3060 feet above the sea. The sea-coast gradually declines in approaching the last point, where it is not more than about 100 feet high. The middle part of the island is lower, and more undulating; its western extremity being marked by the conspicuous Serra Gorda, 1574 feet above the sea; its shores on both sides are low, broken, and rocky. The aspect of the western portion of the island is that of a vast truncated cone, irregularly cut off at an elevation of about 800 feet, and falling on the N., S., and W. sides to a perpendicular coast of between 300 and 800 feet high. In the higher parts an undergrowth of shrubs gives the mountains a rich and wooded appearance. Like all volcanic countries, the face of the island is uneven and irregular, being deeply excavated by numerous ravines, and roughened by streams of semi-vitrified and scoriaceous lava, that resist all atmospheric influences and repel vegetation. Heavy rains falling on the mountains afford a constant supply of water to four lakes at the bottom of extinct craters, and a number of minor reservoirs, and through them to small streams running rapidly down on all sides into the sea (*Geographical Journal*, vol. xv.).

Hot springs abound in many parts of the island, and from almost every crevice vapour is seen issuing. But the most remarkable phenomena are the Caldeiras or boiling fountains, which rise chiefly from a valley called the Furnas, near the western extremity of the island. The water ascends in columns to the height of about 12 feet, after which it dissolves in clouds of vapour. The ground in the immediate vicinity is entirely covered with native sulphur, like hoar frost. At a small distance is the Muddy Crater, the vertex of which, 45 feet in diameter, is on a level with the plain. Its contents are in a state of continual and violent ebullition, accompanied with a sound resembling that of a tempestuous ocean. Yet they never rise above its level, unless occasionally to throw to a small distance a spray of the consistence of melted lead. The Furnas abounds also in hot springs, some of them of a very high temperature. There is almost always, however, a cold spring near to the hot one. These springs have for a considerable period been greatly resorted to in cases of palsy, rheumatism, scrofula, and similar maladies, and bath-rooms and various conveniences for visitors have been erected.

The plains are fertile, producing wheat, barley, and Indian corn; whilst vines and oranges grow luxuriantly on the sides of the mountains. The plants are made to spring even from the interstices of the volcanic rocks, which are sometimes blasted to receive them. Raised in this manner, these fruits are said to be of superior quality; but the expense of such a mode of cultivation necessarily restricts it. The western part of the island yields hemp, which might be raised to a considerable extent. The exports consist of wine, fruit, and provisions, the most important trade being in oranges. Foreign intercourse was at one time confined rigorously to Lisbon; but the inhabitants now trade directly with England, America, and other countries. The exports during 1872 at the port of St Michael's were of the value of £85,279, and the imports amounted to £91,943.

The principal town in the island is Ponta-Delgada, which contains 15,520 inhabitants. It is built with tolerable regularity, the streets being straight and broad. The religious edifices are numerous and elegant. The harbour receives only small vessels; those of larger size must anchor in an open roadstead, which cannot be occupied during the prevalence of southerly gales. A breakwater and harbour of refuge have been in process of construction for a number of years; and a lighthouse is being built at the north-east end of the island. The other towns are Villa Franca, Ribeira Grande, Alagoa, Agoa de Paõ, &c.

St Mary.

St Mary is a small island immediately adjacent to St Michael's, through the medium of which its trade is conducted, as it has no good harbours of its own. It has an area of 36 square miles, and produces wheat in abundance, of which a considerable quantity is exported. Various volcanic rocks are the predominant formations, but beds of limestone also occur, giving rise to numerous stalactite grottoes all over the island. Population from 7000 to 8000.

Terceira.

Terceira (so called as being the third in order of discovery) is smaller than St Michael's, but being placed in a more central position with respect to the other islands, has been chosen as the seat of government. The port of Angra, protected by Mt. Brazil, is also superior to any of those in St Michael's. This island does not exhibit nearly the same extensive traces of volcanic action; and the summits of its mountains are generally level. It abounds in grain and cattle; but the wines are inferior, and fruits are raised merely for internal consumption. The number of inhabitants is estimated at 50,000.

Fayal. Fayal (so called from the extreme abundance of the *faya*, an indigenous shrub) is the most frequented of all the Azores, after St Michael's, as it has one of the best harbours in the islands, and lies directly in the track of vessels that are crossing the Atlantic in any direction. Its principal town is Villa de Horta, with a population of 7636. The town is defended by two castles and a wall, both in decay, and serving rather for show than strength. The city contains two convents for monks and three for nuns, with eight churches. The bay is two miles in length and three-quarters of a mile in breadth, and the depth of water from 6 to 20 fathoms. Though a good roadstead, it is not altogether free from danger in S.S.W. and S.E. winds. The women of this island manufacture fine lace from the agave thread, and till recently produced large quantities of open-work stockings. They also execute carvings in snow-white fig-tree pith, and carry on the finer kinds of basket-making. A small valley, called Flemengos, still perpetuates the name of the Flemish settlers, who have left their mark on the physical appearance of the inhabitants. Population, 26,264.

Pico. A considerable quantity of wine used to be exported from Fayal under the name of Fayal wine, which was really the produce of Pico, one of the most remarkable of the Azores. This island is composed of an immense conical mountain, rising to the height of 7613 feet, and bearing every trace of volcanic formation. The soil consists entirely of pulverised lava. All the lower parts of the mountain used to be in the highest state of cultivation, and covered with vine and orange plantations. But in 1852 the vines were attacked by the *Oidium* fungus and completely destroyed, while the orange-trees suffered almost as much from the *Coccus Hesperidum*. The people were consequently reduced to want, and forced to emigrate in great numbers. The planting of fig-trees and apricots alleviated the evil, and after a time many of the emigrants returned. Pico also produces a valuable species of wood resembling, and equal in quality to, mahogany. Population, 24,000.

Graciosa. Graciosa and St George are two small islands, situated between Fayal and Terceira. Graciosa, as its name imports, is chiefly noted for the extreme beauty of its aspect and scenery. The chief town is Sta Cruz, and the total population 8000. The only manufacture is the burning of bricks. The chief town of St George is Velas, and the population 18,000.

St George.

Corvo and Flores. The two small islands of Corvo and Flores seem but imperfectly to belong to the group. They lie also out of the usual track of navigators; but to those who, missing their course, are led thither, Flores affords good shelter in its numerous bays. Its poultry is excellent; and the cattle are numerous, but small. It derives its name from the abundance of the flowers that find shelter in its deep ravines. Population of Corvo, 1000, and of Flores, 10,508.

Bur. der Admir.*, Berlin, 1873; Kerhallet's *Descr. de l'Archip. des Açores*, 1851, translated by Totten, 1874.

AZOTUS, the name given by Greek and Roman writers to Ashdod, or Eshdod, an ancient city of Palestine, now represented by a few remains in the little village of Esdud, in the pashalik of Acre. It was situated a short distance inland from the Mediterranean, on the usual military route between Syria and Egypt, about 18 geographical miles N.E. of Gaza. As one of the five chief cities of the Philistines, and the seat of the worship of Dagon, it maintained, down even to the days of the Maccabees, a vigorous, though somewhat intermittent, independence against the power of the Israelites, by whom it was nominally assigned to the territory of Judah. In spite of its being dismantled by Uzziah, and somewhat later, in 731 B.C., captured by the Assyrians, it was strong enough in the next century to resist the assaults of Psammetichus for twenty-nine years. Restored by the Roman Gabinius from the ruins in which it had been left by the Jewish wars, it was presented by Augustus to Salome, the sister of Herod. It became the seat of a bishop early in the Christian era, but seems never to have attained any importance as a town.

AZPEITIA, a town of Spain, in the province of Guipuzcoa, on the left bank of the Urola, 15 miles S.W. of San Sebastian. The neighbouring country is fertile, and quarries of marble are wrought in the mountains. During the Carlist movement in 1870–74, Azpeitia was the seat of the Guipuzcoan *Diputacion*, or court for the management of the war; and gunpowder, cartridges, and cannon were manufactured in the town. The famous monastery of San Ignacio, dedicated to Loyola, about a mile distant, was also appropriated for military purposes. Population stated at 2335.

AZTECS, the native name of one of the tribes that occupied the table-land of Mexico on the arrival of the Spaniards in America. It has been very frequently employed as equivalent to the collective national title of Nahuatlecas, or Mexicans. The Aztecs came, according to native tradition, from a country to which they gave the name of Aztlan, usually supposed to lie towards the N.W., but the satisfactory localisation of it is one of the greatest difficulties in Mexican history. The date of the exodus from Aztlan is equally undetermined, being fixed by various authorities in the 11th and by others in the 12th century. One Mexican manuscript gives a date equivalent to 1164 A.D. They gradually increased their influence among other tribes, until, by union with the Toltecs, who occupied the table-land before them, they extended their empire to an area of from 18,000 to 20,000 square leagues. The researches of Humboldt gave the first clear insight into the early periods of their history. See MEXICO.

AZUNI, DOMENICO ALBERTO, a distinguished jurist and writer on international law, was born at Sassari, in Sardinia, in 1749. He studied law at Sassari and Turin, and in 1782 was made judge of the consulate at Nice. In 1786–88 he published his *Dizionario Universale Ragionato della Giurisprudenza Mercantile*. In 1795 appeared his systematic work on the maritime law of Europe, *Sistema Universale dei Principii del Diritto Maritimo dell' Europa*, of which a second edition was demanded in the following year. A French translation by Digeon was published in 1798, and in 1805 Azuni recast the work, and translated it into French. In 1806 he was appointed one of the French commission engaged in drawing up a general code of commercial law, and in the following year he proceeded to Genoa as president of the court of appeal. After the fall of Napoleon in 1814, Azuni lived for a time in retirement at Genoa, till he was invited to Sardinia by Victor Emmanuel I., and appointed judge of the consulate at Cagliari, and director of the university library. He resided at Cagliari till his death in 1827. Besides the works above mentioned, Azuni wrote numerous pamphlets and minor works, chiefly on maritime law, an important treatise on the origin and progress of maritime law (Paris, 1810), and an historical, geographical, and political account of Sardinia (1st ed. 1799; 2d, much enlarged, 1802).

B

B is the second symbol of all European alphabets except those derived from the Cyrillic original (see ALPHABET, vol. i. p. 613), such as the Russian. In these a modified form, in which only the top of the upper loop appears, stands as the second letter, with the value of the original sound *b*; whilst the old symbol B comes third with the phonetic value *v* or *w*. In Egypt this letter was originally a hieroglyph for a crane, and afterwards represented also the sound *b*. The symbol and its phonetic value were borrowed by the Phœnicians, but not its name, as we infer from finding it called in Hebrew *beth*, *i.e.*, a house. In its oldest known Phœnician form the upper loop only exists in a more or less rounded shape. In different alphabets even the upper loop was gradually opened, so that in the square Hebrew the original form can no longer be detected. The Greeks, when they borrowed it from the Phœnicians, closed up the lower loop as well as the upper for convenience of writing. Sometimes the loops were angular, but more generally they were rounded. There is little variation of the form, except in the old alphabets of Corinth and Corcyra, where the original is hardly recognisable. In old Latin both the rounded and the pointed loops appear.

The original sound which this symbol represented, and which it still represents in most European languages, is a closed labial, *i.e.*, one in which perfect closure of the lips is necessary, the sound being heard as the lips open. Like all closed sounds, it is not capable of prolongation. It differs from *p*, which is also a closed labial, as a sonant from a surd. A sonant is heard when the breath, as it passes through the glottis, is vocalised by the tension or approximation of its edges. When there is no such action of the glottis, mere breath alone passes through; but the explosiveness of the breath when the vocal organs are opened produces a sound, and this is called a surd. The vocal organs are in precisely the same position for *p* as for *b*; but in producing *p* they act upon breath only; in producing *b* they articulate voice.

In the earliest stage to which we can trace back the language spoken by the forefathers of the Indo-European nations, it cannot be certainly proved that the sound *b* was ever heard at the beginning of a word. Perhaps in this position it may have been sounded indistinctly as a labial *v*. In English and all Low German languages *p* has taken the place of original *b*, which is preserved in Greek and Latin; thus the *b* in κάνναβις is replaced by *p* in English "hemp." We do not certainly know the reason of this shifting of sound, which affects all momentary sounds, and which is commonly known in England by the name of "Grimm's law." By the same law English *b* has taken the place of original *bh*. Thus our "beech" stands for original "bhaga," which is represented, according to the phonetic laws of the languages, by Greek φηγός and Latin "fagus." In the middle of a Latin word, and consequently generally in the languages derived from the Latin, *b* represents original *bh*.

There is a tendency among some peoples to allow the *b* sound to pass into a *v*, in which the lips are not firmly closed, and so the sound is capable of prolongation, because it does not consist (as *b* proper does) in the momentary escape of the voice after the lips have been compressed and then opened. This *v*, in the production of which the lips alone are concerned, must be carefully distinguished from our English *v*, which is the result of pressure between the upper teeth and lower lip; it is more like our English *w*. It is the sound which has taken the place of *b* in modern Greek. The same confusion is found in Latin inscriptions of the 3d and 4th centuries after Christ, when the symbol *v* represents original *b*; thus *sivi* stands for *sibi*, *livido* for *libido* (see Corssen, *Aussprache*, &c., i. 131); and still more frequently *b* appears for *v*, as *bixit* for *vixit*. The change would be inconceivable if the symbol *v* in these cases had had the same sound as with us, that of a labiodental. The same indistinctness appeared locally in dialects, as is shown by Martial's well-known epigram—

> "Haud temere antiquas mutat Vasconia voces,
> Cui nil est aliud *vivere* quam *bibere*."

BAADER, FRANZ XAVER VON, an eminent German philosopher and theologian, born 27th March 1765 at Munich, was the third son of F. P. Baader, court physician to the elector of Bavaria. His two elder brothers were both distinguished, the eldest, Clemens, as an author, the second, Joseph, as an engineer. Franz when young was extremely delicate, and from his seventh to his eleventh year was afflicted with a species of mental weakness, which singularly enough disappeared entirely when he was introduced for the first time to the mathematical diagrams of Euclid. His progress thenceforth was very rapid. At the age of sixteen he entered the university of Ingolstadt, where he studied medicine, and graduated in 1782. He then spent two years at Vienna, and returning home, for a short time assisted his father in his extensive practice. This life he soon found unsuited for him, and he decided on becoming a mining engineer. He studied under Werner at Freiberg, travelled through several of the mining districts in North Germany, and for four years, 1792-1796, resided in England. There he became acquainted with the works of Jakob Böhme, and at the same time was brought into contact with the rationalistic 18th-century ideas of Hume, Hartley, and Godwin, which were extremely distasteful to him. For Baader throughout his whole life had the deepest sense of the *reality* of religious truths, and could find no satisfaction in mere reason or philosophy. "God is my witness," he writes in his journal of 1786, "how heartily and how often I say with Pascal, that with all our speculation and demonstration we remain without God in the world." Modern philosophy he thought essentially atheistic in its tendencies, and he soon grew to be dissatisfied with the Kantian system, by which he had been at first attracted. Particularly displeasing to him was the ethical autonomy, or the position that man had in himself a rule of action, that duty contained no necessary reference to God. This Baader called "a morality for devils," and passionately declared that if Satan could again come upon earth, he would assume the garb of a professor of moral philosophy. The mystical, but profoundly religious, speculations of Eckhart, St Martin, and above all of Böhme, were more in harmony with his mode of thought, and to them he devoted himself. In 1796 he returned from England, and in his passage through Hamburg became acquainted with Jacobi, the *Faith* philosopher, with whom he was for many years on terms of close friendship. He now for the first time learned something of Schelling, and the works he published during this period were manifestly influenced by that philosopher. Yet Baader is no disciple of Schelling, and probably, in the way of affecting the future course of Schelling's thought, gave out more than he received. Their personal friendship continued till about the year 1822, when Baader's vehement denunciation of modern

philosophy in his letter to the Czar of Russia entirely alienated Schelling.

While prosecuting his philosophical researches, Baader had continued to apply himself diligently to his profession of engineer. He gained a prize of 12,000 gulden (about £1000) for his new method of employing Glauber's salts instead of potash in the making of glass. From 1817 to 1820 he held the post of superintendent of mines, and was raised to the rank of nobility for his services. He retired from business in 1820, and soon after published one of the best of his works, *Fermenta Cognitionis*, 6 pts., 1822-25, in which he combats modern philosophy, and recommends the study of J. Böhme. In 1826, when the new university was opened at Munich, he was appointed professor of philosophy and speculative theology. Some of the lectures delivered there he published under the title, *Spekulative Dogmatik*, 4 pts., 1827-1836. In 1838 he opposed the interference in civil matters of the Roman Catholic Church, to which he belonged, and in consequence was, during the last three years of his life, interdicted from lecturing on the philosophy of religion. He died 23d May 1841.

It is extremely difficult to give in moderate compass an adequate view of Baader's philosophy; for he himself generally either gave expression to his deepest thoughts in brief, obscure aphorisms, or veiled them under mystical symbols and analogies. In this respect his style of exposition is not undeserving of Zeller's strictures (*Ges. d. deut. Phil.*, 732, 736). Further, he has no systematic works; his doctrines were for the most part thrown out in short detached essays, in comments on the writings of Böhme and St Martin, or in his extensive correspondence and journals. For his own part, he was distinctly of opinion that philosophy is not as yet capable of reduction to scientific form, and it would consequently be an error to demand from him a rigidly coherent body of truth. At the same time, the general tendency of his thought is very apparent, and there are some salient points which stand out with a clearness sufficient to render possible an outline of his whole course of speculation. In the mode in which he approaches the problems of philosophy, Baader is entirely opposed to the modern speculative spirit, which, beginning with Descartes, has endeavoured to erect a rational or coherent system on the basis of self-consciousness alone, and has protested against the presupposition of anything which can fetter reason, and against the acceptation of any truth which cannot be rationally construed. He starts from the position that human reason is in a corrupt condition, and by itself can never reach the end it aims at, and maintains that we cannot throw aside the presuppositions of faith, church, and tradition. His point of view may, with some truth, be described as Scholasticism; for, like the great scholastic doctors, he believes that theology and philosophy are not opposed sciences, but that reason has to make clear the truths given by authority and revelation. But in his attempt to draw still closer the realms of nature and of grace, of faith and knowledge, of human thought and divine reason, he approaches more nearly to the mysticism of Eckhart, Paracelsus, and Böhme. All self-consciousness, he thinks, is at the same time God-consciousness; our knowledge is never mere *scientia*, it is invariably *con-scientia*—a knowing with, consciousness of, or participation in God. Of this knowledge, as of knowledge in general, there are three grades:—(1.) Where the thing known impresses itself upon us without or against the will, where the knowledge is necessary,—such, *e.g.*, is the knowledge *that* God is; (2.) Where the thing known is cognised by an act on our part, where knowledge is free,—such, *e.g.*, is the voluntary belief or trust *in* God; (3.) Where the thing known enters into, and forms part of, the very process of knowing,—such is the *speculative* knowledge of God, wherein we recognise that without God we are not, and that we know Him only in and through His knowledge of us. The notion of God is thus the fundamental thought of Baader; his philosophy is in all essentials a theosophy, and its first great problem is to determine accurately the nature of the divine Being. Now God, who is, according to Baader, the primary will which lies at the basis of all things, is not to be conceived as mere abstract Being, *substantia*, but as everlasting process, activity, *actus*. Of this everlasting process, this self-generation of God, we may distinguish two aspects—the immanent or esoteric, and the emanent or exoteric. God has reality only in so far as He is absolute spirit, and only in so far as the primitive will cognises or is conscious of itself can it become spirit at all. But in this very cognition of self is involved the distinction of knower and known, producer and produced, from which proceeds the power to become spirit. This immanent process of self-consciousness, wherein indeed a trinity of persons is not given but only rendered possible, is mirrored in, and takes place through, the eternal and impersonal idea or wisdom of God, which exists beside, though not distinct from, the primitive will. Concrete reality or personality is given to this divine *Ternar*, as Baader calls it, through *nature*, the principle of self-hood, of individual being, which is eternally and necessarily produced by God. Only in nature is the trinity of *persons* attained. These processes, it must be noticed, are not to be conceived as successive, or as taking place in time; they are to be looked at *sub specie æternitatis*, as the necessary elements or moments in the self-evolution of the divine Being. Nor is *nature* to be confounded with created substance, or with matter as it exists in space and time; it is pure non-being, the mere otherness, *alteritas*, of God—his shadow, desire, want, or *desiderium sui*, as it is called by mystical writers. Creation is itself a free and non-temporal act of God's love and will, and on this account its reality cannot be speculatively deduced, but must be accepted as an historic fact. Created beings were originally of three orders—the intelligent, or angels; the non-intelligent natural existences; and man, who mediated between these two orders. Intelligent beings are endowed with freedom; it is possible, but not necessary, that they should fall. Hence the fact of the fall is not a speculative, but an historic truth. The angels fell through pride—through desire to raise themselves to equality with God; man fell by lowering himself to the level of nature. Only after the fall of man begins the creation of space, time, and matter, or of the world as we now know it; and the motive of this creation was the desire to afford man an opportunity for taking advantage of the scheme of redemption, for bringing forth in purity the image of God according to which he has been fashioned. The physical philosophy and anthropology which Baader, in connection with this, unfolds in various works, is but little instructive, and coincides in the main with the semi-intelligible utterances of Böhme. In nature and in man he finds traces of the dire effects of sin, which has corrupted both, and has destroyed their natural harmony. As regards ethics, it has been already pointed out that Baader rejects the Kantian or any autonomic system of morals. Not obedience to a moral law, but realisation in ourselves of the divine life, through and in which we have our being, is the true ethical end. But man has lost the power to effect this by himself; he has alienated himself from God, and therefore no ethical theory which neglects the facts of sin and redemption is satisfactory or even possible. The history of man and of humanity is the history of the redeeming love of God. The means whereby we put ourselves so in relation with Christ as to receive from Him his healing virtue, are chiefly prayer and

the sacraments of the church, though it must be noted that mere works are never sufficient. With regard to man in his social relations there are two great institutions or systems of rules under which, or in connection with which, he stands. One is temporal, natural, and limited—the state; the other is eternal, cosmopolitan, and universal—the church. In the state two things are requisite: first, common submission to the ruler, which can only be secured or given when the state is Christian, for God alone is the true ruler of men; and, secondly, inequality of rank, without which there can be no organisation. A despotism of mere power, and liberalism, which naturally produces socialism, are equally objectionable. The ideal state is a perfectly organised church society, a civil community ruled by a universal or Catholic church, and the principles of this church are equally distinct from mere passive pietism, or faith which will *know* nothing, and from the Protestant doctrine, which is the very radicalism of reason.

Baader is, without doubt, the greatest speculative theologian of modern Catholicism, and his influence has extended itself even beyond the precincts of his own church. The great work of Rothe, *Theologische Ethik*, is thoroughly impregnated with his spirit; and, not to mention others, J. Müller, *Christ. Lehre v. der Sünde*, and Martensen, *Christ. Dogmatik*, show evident marks of his influence.

His works have been collected and published by a number of his adherents—Hoffmann, Hamberger, E. v. Schaden, Lutterbeck, Von Osten-Sacken, and Schlüter—*Baader's Sämmtliche Werke*, 16 vols., 1851-60. Valuable introductions by the editors are prefixed to the several volumes. Vol. xv. contains a full biography; vol. xvi., an index, and an able sketch of the whole system by Lutterbeck. Among the most valuable works in elucidation or development of Baader's philosophy may be named:—Hoffmann, *Vorhalle zur Spekulativen Lehre Baader's*, 1836; *Grundzüge der Societäts-Philosophie Franz Baader's*, 1837; *Philosophische Schriften*, vols., 1868-72; *Die Weltalter*, 1868; Hamberger, *Cardinalpunkte der Baaderschen Philosophie*, 1855; *Fundamentalbegriffe von F. B.'s Ethik, Politik, u. Religions-Philosophie*, 1858; Lutterbeck, *Philosophische Standpunkte Baader's*, 1854; *Baader's Lehre vom Weltgebäude*, 1866. The only satisfactory survey in any history of philosophy is that given by Erdmann, *Versuch einer Gesch. d. neuern Phil.*, iii. 2, pp. 583-636. (R. AD.)

BAAL is a Semitic word, which primarily signifies *lord* or *owner*, and then, in accordance with the Semitic way of looking at family and religious relations, is specially appropriated to express the relation of a *husband* to his wife, and of the *deity* to his worshipper. In the latter usage, which does not occur among the Arabian Semites, the word Baal seems at first to have been a mere title of deity and not a proper name. In the Old Testament it is regularly written with the article—"the Baal;" and the Baals of different tribes or sanctuaries were not necessarily conceived as identical, so that we find frequent mention of Baalim, or rather "the Baalim," in the plural. There is even reason to believe that at an early date the Israelites applied the title of Baal to Jehovah himself, for one of Saul's sons is named Esh-baal (1 Chron. viii. 33), while everything we know of Saul makes it most unlikely that he was ever an idolater. Afterwards, when the name Baal was exclusively appropriated to idolatrous worship (*cf.* Hos. ii. 16, 17), abhorrence for the unholy word was marked by writing *Bosheth* (shameful thing) for Baal in compound proper names, and thus we get the usual forms Ishbosheth, Mephibosheth. (*Cf.* Ewald, *Geschichte*, ii. 537, and Wellhausen, *Text der Bücher Samuelis*, pp. xii. 30, where more arguments are adduced for this view.)

The great difficulty which has been felt by investigators in determining the character and attributes of the god Baal mainly arises from the originally appellative sense of the word, and many obscure points become clear if we remember that when the title became a proper name it might be appropriated by different nations to quite distinct deities, while traces of the wider use of the word as a title for any god, might very well survive even after one god had come to be known as Baal *par excellence*. That Baal is not always one and the same god was known even to the ancient mythologists, who were very much disposed to fuse together distinct deities; for they distinguish an "old" Baal or Belitan (Bel êthan) from a younger Baal, who is sometimes viewed as the son of the other. The "old" Baal has sometimes been identified with the planet Saturn, but it is more likely that he is the Baal (in Assyrian pronunciation Bil) of the first triad of the Babylonian Pantheon, that is the Bel, as distinct from the Baal, of the Old Testament. This Assyrian and Babylonian Bel is no mere solar or planetary god, but is represented in Chaldean cosmogony as the shaper of heaven and earth, the creator of men and beasts, and of the luminaries of heaven (*Berosus*, ed. Richter, p. 50). At the same time, we find that the inscriptions give the title of Bel to other and inferior gods, especially to Merodach or the planet Jupiter. This planet was, we know, the Baal (Bâl, Bil) of the heathen Mesopotamians (Sabians) of later times, and of the Babylonian Mendeans.

The Baal of the Syrians, Phœnicians, and heathen Hebrews is a much less elevated conception than the Babylonian Bel. He is properly the sun-god, Baal Shamem, Baal (lord) of the heavens, the highest of the heavenly bodies, but still a mere power of nature, born like the other luminaries from the primitive chaos (*Sanchoniathon*, ed. Orelli, pp. 10, 14). As the sun-god he is conceived as the male principle of life and reproduction in nature, and thus in some forms of his worship is the patron of the grossest sensuality, and even of systematic prostitution. An example of this is found in the worship of Baal-Peor (Num. xxv.), and in general in the Canaanitish high places, where Baal, the male principle, was worshipped in association with the unchaste goddess Ashera, the female principle of nature. The frequent references to this form of religion in the Old Testament are obscured in the English version by the rendering "grove" for the word Ashera, which sometimes denotes the goddess, sometimes the tree or post which was her symbol. Baal himself was represented on the high places not by an image, but by obelisks or pillars (*Maççeboth*, E. V. wrongly "*images*"), sometimes called *chammanim* or sun-pillars, a name which is to be compared with the title Baal-chamman, frequently given to the god on Phœnician inscriptions. There is reason to believe that these symbols, in their earliest form of the sacred tree and the sacred stone, were not specially appropriated to Baal worship, but were the mark of any sanctuary, memorials of a place where the worshipper had found God (see, for example, Gen. xxi. 33, where for *grove* read *tamarisk*, Gen. xxviii. 18), while the stone pillar was also a primitive altar. Gradually, however, they came to be looked upon as phallic symbols, appropriate only to sensual nature worship, and as such were attacked by the prophets (Micah v. 13, 14; Isa. xvii. 8, xxvii. 9, &c.), and destroyed by such orthodox kings as Josiah. The worship of Baal among the Hebrews has two distinct periods—one before the time of Samuel, and a second from the introduction of the Tyrian worship of Baal by Ahab, who married a Phœnician princess. The ritual of this new Baal, with his long train of priests and prophets, his temple and sacred vestments (2 Kings x.), was plainly much more splendid than the older Canaanitish worship. Of the worship of the Tyrian Baal, who is also called Melkart (king of the city), and is often identified with the Greek Heracles, but sometimes with the Olympian Zeus, we have many accounts in ancient writers, from Herodotus downwards. He had a magnificent temple in insular Tyre, founded by Hiram, to which gifts streamed from all countries, especially at the great feasts. The solar character of this deity appears especially in the annual feast of his awakening shortly after

the winter solstice (Joseph., *Ant.*, viii. 5). At Tyre, as among the Hebrews, Baal had his symbolical pillars, one of gold and one of smaragdus, which, transported by phantasy to the Farthest West, are still familiar to us as the pillars of Hercules. The worship of the Tyrian Baal was carried to all the Phœnician colonies. His name occurs as an element in Carthaginian proper names (Hanni*bal*, Asdru*bal*, &c.), and a tablet found at Marseilles still remains to inform us of the charges made by the priests of the temple of Baal for offering sacrifices.

A much-disputed question is the relation of the sun-god Baal to Moloch-Saturn. Moloch is certainly called Baal in Jer. xix. 5, xxxii. 35, but the word may here retain its appellative force. It is, however, the theory of many scholars, especially worked out by Movers, that Moloch is only a special development of Baal, representing the destructive heat instead of the life-giving power of the sun. Another question of some nicety concerns the precise character and mutual relations of the female deities associated with Baal. In the Old Testament, as we have seen, Baal is generally associated with Ashera, but sometimes with Ashtoreth or Astarte (in the plural Ashtaroth, associated with the plural Baalim, 1 Sam. vii. 4, &c.) As Ashtoreth is constantly associated with the Phœnician Baal, it was long customary to identify Ashera with her, a theory opposed to the fact that Ashtoreth is represented as a chaste goddess. The key to the difficulty is probably to be sought in the Assyrian mythology, where we find that the planet Venus was worshipped as the chaste goddess Istar, when she appeared as a morning star, and as the impure Bilit or Beltis, the Mylitta of Herod. (i. 199), when she was an evening star. These two goddesses, associated yet contrasted, seem to correspond respectively to the chaste Ashtoreth and the foul Ashera, though the distinction between the rising and setting planet was not kept up among the Western Semites, and the nobler deity came at length to be viewed as the goddess of the moon.

Finally, we may mention as a special form of Baal the Philistine Baal-zebub, or "Baal of flies," a conception which has more than one analogy in Greek religion, especially the Ζεὺς Ἀπόμυιος at Olympia. The use of the word Beelzebub, or rather, with a slight change, Beelzebul, by the later Jews, to denote the prince of the devils (Mat. xii. 24), is easily understood on the principle laid down in 1 Cor. x. 20.

For further information as to Baal, the reader may consult works on Syrian and Phœnician religion. Of older books, the most celebrated is Selden's *De diis Syris*; of recent books, Movers's *Die Phönizier*, i., a work full of learning, but deficient in method and logic. The valuable contributions to the subject from Assyrian research are partly brought together by Schrader in the *Stud. und Krit.* for 1874, pp. 335, *sqq.* (W. R. S.)

BAALBEC, or BA'ALBAK, an ancient city of Syria, celebrated for the magnificence of its ruins, which, with the exception of those at Palmyra, are the most extensive in that region. The derivation of the latter part of the name is still dubious, some boldly identifying it with the Egyptian *baki*, a city, and others comparing it with the Arabic *bakha*, "to be thronged." It is almost certain that the Greek Heliopolis was intended to be a translation of the name. The town is pleasantly situated on the lowest declivity of the Anti-Libanus, at the opening of a small valley into the plain of El-Buká'a or Sahlat Ba'albak, about 35 miles N.N.W. of Damascus, and 38 S.S.E. of Tripoli. The inhabitants have a saying, Burton informs us, that it lies *on the balance*, meaning that it occupies the flattened crest of a watershed. By Russegger its height above the sea is given at 3496 Paris feet, and by Schubert at 3572,—the mean of the observations being 3584 Paris feet, or 4502 English feet. A small stream, rising in the immediate neighbourhood from a fountain known as Ra'as-el Ayn, is employed for the irrigation of the valley.

The origin of Baalbec is lost in remote antiquity, and the historical notices of it are very scanty. The silence of the classical writers respecting it would seem to imply that previously it had existed under another name, and various attempts have been made to identify it with certain places mentioned in the Bible, as with Baalgad, "in the valley of Lebanon" (Josh. xi. 17); Baalath, one of Solomon's cities (1 Kings ix. 18); Baal-hamon, where Solomon had a vineyard (Cant. viii. 11); and "the plain of Aven" (Bikath-Aven, Amos i. 5), referred to by Amos; but none of these identifications seem to rest on any very solid support, though they have each in turn met the approval of some writer of authority. In the absence of more positive information, we can only conjecture that its situation on the high road of commerce between Tyre and Palmyra and the farther East rendered it at an early period a seat of wealth and splendour. It is not at all improbable that the statement of Macrobius in his *Saturnalia* may be founded on the tradition of a real and potent connection between Heliopolis and its Egyptian namesake. It is mentioned by Josephus (*Ant.*, xiv. 3, 4), Pliny (*Nat. Hist.*, v. 22), and Ptolemy, and coins of the city have been found belonging to the reigns of almost all the emperors from Nerva to Gallienus. John Malala of Antioch ascribes the erection of a great temple to Jupiter (ναὸν τῷ Διὶ μέγαν) at Heliopolis to Antoninus Pius; and two votive inscriptions still exist on the bases of columns in the Greater Temple, belonging to the age of Septimius Severus. From the civic coins of the reigns of Nerva and Hadrian we learn that the city had been constituted a colony by Julius Cæsar, and that it was the seat of a Roman garrison in the time of Augustus, and obtained the *Jus Italicum* from Septimius Severus (Ulpian, *De Censibus*, lib. i.). Some of the coins of this last emperor bear the figure of a temple and the legend COL.HEL.I.O.M.H., *Colonia Heliopolis Jovi Optimo Maximo Heliopolitano*; while one of the reign of Valerian has the representation of two temples.

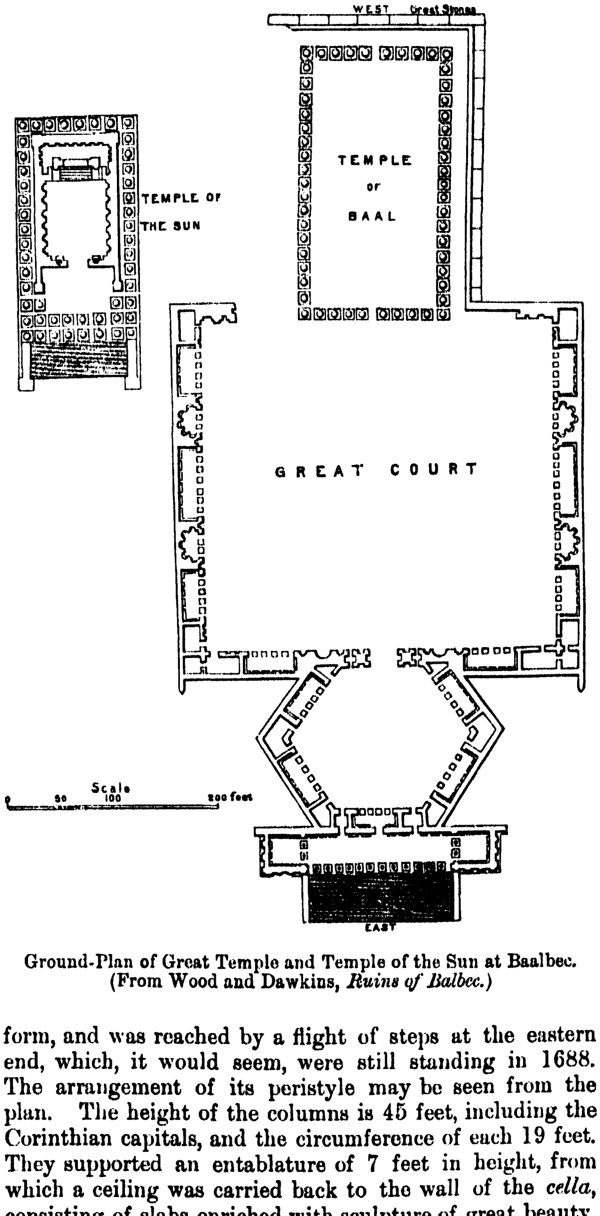
It is evident that in the early Christian centuries Heliopolis was one of the most flourishing seats of Pagan worship, and the Christian writers draw strange pictures of the morality of the place. In 297 it became the scene of the martyrdom of Gelasinus. The Emperor Constantine, according to Sozomen, issued a rescript against the licentious rites of the people, and founded a *basilica* among them; but, on the accession of Julian, the Pagan population broke out into violent persecution, and the city became so notorious for its hostility to Christianity, that Christians were banished thither from Alexandria as a special punishment. Theodosius the Great is said to have turned "the temple of *Balanius*, the Trilithon," into a Christian church, and the city seems to have been the seat of a bishop.

From the accounts of Oriental writers, Baalbec seems to have continued a place of importance down to the time of the Moslem invasion of Syria. They describe it as one of the most splendid of Syrian cities, enriched with stately palaces, adorned with monuments of ancient times, and abounding with trees, fountains, and whatever contributes to luxurious enjoyment. After the capture of Damascus it was regularly invested by the Moslems, and after a courageous defence, at length capitulated. The ransom exacted by the conquerors was 2000 ounces of gold, 4000 ounces of silver, 2000 silk vests, and 1000 swords, together with the arms of the garrison. The city afterwards became the mart for the rich pillage of Syria; but its prosperity soon received a fatal blow from the caliph of Damascus, by whom it was sacked and dismantled, and the principal in-

habitants put to the sword (748 A.D.). It continued, however, to be a place of military importance, and was frequently an object of contest between the caliphs of Egypt and the various Syrian dynasties. In 1090 it passed into the hands of the Seljuk princes of Aleppo and Damascus, who in 1134 were disputing its possession among themselves, and had to yield in 1139 to the power of Genghis Khan. He held the city till 1145, when it reverted to Damascus, and continued mostly, from that time, to follow the fortunes of that city. During the course of the century it suffered severely from one or more of the earthquakes that visited the district in 1139, 1157, 1170. In 1260 it was taken by the forces of Hulagu, who destroyed the fortifications; but, in the 14th century, it is again described by Abulfeda as enclosed by a wall with a large and strong fortress. Whether it was Baalbec, or, as others say, Cairo, that was, in 1367, the birthplace of Takkieddin Ahmed, the Arabic historian, he appears to have derived the name by which he is best known, El-Makrizi, from one of the quarters of the city. In 1400 it was pillaged by Timur in his progress to Damascus; and afterwards it fell into the hands of the Metaweli, a barbarous predatory tribe, who were nearly exterminated when Djezzar Pacha permanently subjected the whole district to Turkish supremacy.

The ancient walls of the city are about 4 miles in compass; but the present town is, with the exception of some portions of its Saracenic fortifications and its two mosques, a cluster of mean-looking buildings, which serve only to bring out into greater prominence the grandeur of the neighbouring ruins. These consist of three temples, usually known as the Great Temple (and it well deserves the name), the Temple of Jupiter, Apollo, or the Sun, and the Circular Temple. The Great Temple (*vide* Plan), which would seem at one period to have been a kind of pantheon, is situated on a magnificent platform, which raises it high above the level of the ground, and extends from east to west a distance of about 1100 feet. The portico is at the eastern end, and must have been reached by a grand flight of steps. It is 180, or, including the exedræ or pavilions, 260 feet from north to south. A threefold entrance leads into the first court, which is hexagonal in shape, and measures about 250 feet from corner to corner. A portal 50 feet wide, flanked on each side by a smaller aperture of 10 feet, gives admittance to the great quadrangle, which extends from east to west for 440 feet, and has a breadth of 370, thus including an area of between 3 and 4 acres. On all sides, except the eastern, where the "stately stairs" led up to the temple front, this court was surrounded with exedræ of various dimensions, enclosed by costly pillars, and adorned with numerous statues; but statues and pillars and steps are now all involved in a common confusion. The peristyle of the temple proper was composed of fifty-four columns, the front line consisting of ten and the side line of nineteen each. The height of the shafts was about 62 feet, and their diameter 7 feet at the base and about 5 feet at the top. They were crowned with rich Corinthian capitals, and supported an entablature of 14 feet in height (Col. Chesney says 11 feet 9 inches). Most of them were formed of three blocks, united without cement by strong iron dowels. Only six of these columns still stand at the western end of the southern side—three having fallen since the visit of Wood and Dawkins in 1750. That part of the great platform on which the peristyle rests consists of immense walls built up about 50 feet from the ground, and formed, as may be easily seen on the northern side, of thirteen courses of bevelled stones in alternate layers of longer and shorter blocks. Outside these walls, at a distance of 29½ feet, is another (so-called *substruction*) wall on the north, west, and probably, though concealed by rubbish, also on the east side. This is built of large stones, and contains three blocks of such extraordinary proportions that the temple acquired from them its ancient name of Trilithon, or "Three-Stone-Temple." These measure respectively 64 feet, 63 feet 8 inches, and 63 feet in length, are 13 feet in height, and have been raised 20 feet from the ground in the western wall. Two underground passages, 17 feet wide and 30 feet high, run from east to west along the sides of the platform of the great quadrangle, and are connected by a transverse tunnel of similar description. They seem, from inscriptions on the walls, to have been tenanted at some time by Roman soldiery.

Slightly to the north of the Great Temple, and agreeing with it in its orientation, is the Temple of the Sun, which is in much better preservation than its neighbour, and, though small in comparison with it, is larger than the Parthenon at Athens. It likewise is built on a plat-



Ground-Plan of Great Temple and Temple of the Sun at Baalbec. (From Wood and Dawkins, *Ruins of Balbec.*)

form, and was reached by a flight of steps at the eastern end, which, it would seem, were still standing in 1688. The arrangement of its peristyle may be seen from the plan. The height of the columns is 45 feet, including the Corinthian capitals, and the circumference of each 19 feet. They supported an entablature of 7 feet in height, from which a ceiling was carried back to the wall of the *cella*, consisting of slabs enriched with sculpture of great beauty. The principal ornament of each slab is a hexagonal moulding enclosing the figure of some god or hero; but the profusion and elegance of the fretwork can only be rendered by the artist. After passing the vestibule, which was partly freed from its barbarous screen by Mr Burton in

1870, we reach "an exquisitely-carved doorway, having a staircase on each side leading to the top of the building," which gives entrance to the interior of the temple. On the soffit is the figure of the eagle referred to by so many of the travellers, and regarded by Volney and others as the emblem of the sun-god. This part of the building was greatly damaged in the earthquake of 1759, and if measures are not taken to support the lintel, it must soon fall to the ground. The *cella* seems to have been hypæthral; and, like the rest of the building, it was richly ornamented, the floor now presenting a mass of broken sculpture and pillars. A spiral staircase, in the interior of a massive column, leads to the roof on each side of the portal.

Further east stands the Circular Temple, which is of very small dimensions, but of beautiful workmanship and design. It consists of a semicircular *cella* surrounded on the outside by eight Corinthian columns, while within there is a double tier of smaller pillars, the lower row being Ionic and the upper Corinthian. Down to the last century it was used as a Greek church; but it is now in a very ruinous condition, and "choked with wretched hovels." It is known to the people of Baalbec as Barbárat-el Atikah (*La Sainte Barbe*).

The remains of the military works of the Saracens and their successors are only too numerous about Baalbec; but they have left no buildings of greater interest than the mosques already mentioned, the larger of which was built by Melek el As'ad, and the smaller by his father, Melek el Zahir (670 A.H.). Several interesting excursions may be made in the neighbourhood, in regard to which the reader may consult Murray's *Handbook*, Joanne and Isambert's *Itinéraire*, and a letter of Mrs Burton's in *Unexplored Syria.*

The ruins of Baalbec have awakened the admiration of European travellers from the 16th century down to the present day. Baumgarten visited them in 1507, Belon in 1548, Thevet in 1550, Melchior von Seydlitz in 1557, Radzivil in 1583, Quaresmius in 1620, Monconys in 1647, De la Roque in 1688, and Maundrell in 1699. In the 18th century Pococke gave a sketch of the ruins, which was followed up by the magnificent work of Wood and Dawkins (1751), to this day one of our principal authorities, and Volney, in 1784, supplied a graphic description. During the present century the number of travellers who have visited Baalbec has enormously increased; it may be sufficient to mention Richardson, Addison, Lindsay, Wilson, the Duke of Ragusa, Lamartine, De Saulcy, Chesney, and Robinson. Of the chapters of the last writer, in his *Biblical Researches*, vol. iii., especial use has been made in the present article. In spite, however, of such a series of investigators, much might still be done to extend our knowledge of those wonderful remains. A few superficial excavations have been made from time to time; but the ruins of Baalbec still wait for their Layard or their Schliemann.

BABATAG, or BABADAG, a city of Turkey in Europe, in the government of Bulgaria and sanjak of Silistria. It stands on the lake or estuary Rasein, which communicates with the Black Sea, and is surrounded by mountains covered with woods. It used to be the winter headquarters of the Turkish army during their wars with Russia; and, in 1854, it was bombarded by the Russians. Long. 28° 32′ E., lat. 44° 55′ N. The population of 10,000 includes many Jews, Armenians, Tatars, and Greeks. Babatag was founded by Bajazet.

BABBAGE, CHARLES, a distinguished English mathematician and mechanician, was born, 26th December 1792, at Teignmouth in Devonshire. He was educated at a private school, and afterwards entered S. Peter's College, Cambridge, where he graduated in 1814. Though he did not compete in the mathematical tripos, he acquired a great reputation at the university. In the year after his graduation he contributed a paper on the "Calculus of Functions" to the *Philosophical Transactions*, and in 1816 was made a fellow of the Royal Society. Along with Herschel and Peacock he laboured to raise the standard of mathematical instruction in England, and specially endeavoured to supersede the Newtonian by the Leibnitzian notation in the Calculus. With this object the three friends translated, in 1816, Lacroix's *Treatise on the Differential and Integral Calculus*, and added, in 1820, two volumes of examples. Mr Babbage's attention seems to have been very early drawn to the number and importance of the errors introduced into astronomical and other calculations through inaccuracies in the computation of tables. He contributed to the Royal Society some notices on the relation between notation and mechanism; and in 1822, in a letter to Sir H. Davy on the application of machinery to the calculation and printing of mathematical tables, he discussed the principles of a calculating engine, to the construction of which he devoted many years of his life. Government was induced to grant its aid, and the inventor himself spent a portion of his private fortune in the prosecution of his undertaking. He travelled through several of the countries of Europe, examining different systems of machinery; and some of the results of his investigations were published in the admirable little work, *Economy of Machines and Manufactures*, 1834, which Blanqui has called "a hymn in honour of machinery." The great calculating engine was never completed; the constructor apparently desired to adopt a new principle when the first specimen was nearly complete, to make it not a difference but an analytical engine, and Government declined to accept the further risk. From 1828 to 1839 Babbage held the office of Lucasian professor of mathematics at Cambridge. He contributed largely to several scientific periodicals, and was instrumental in founding the Astronomical and Statistical Societies. He only once endeavoured to enter public life, when, in 1832, he stood unsuccessfully for the borough of Finsbury. During the later years of his life he resided in London, and, surrounded by his workshops, still continued to devote himself to the construction of machines capable of performing arithmetical and even algebraical calculations. He died at London, 18th October 1871. He gives a few biographical details in his *Passages from the Life of a Philosopher*, 1864, a work which throws considerable light upon his somewhat peculiar character. His works, pamphlets, and papers were very numerous; in the *Passages* he enumerates eighty separate writings. Of these the most important, besides the few already mentioned, are, *Tables of Logarithms*, 1826; *Comparative View of the Various Institutions for the Assurance of Lives*, 1826; *Decline of Science in England*, 1830; *Ninth Bridgewater Treatise*, 1837; *The Exposition of* 1851, 1851.

BABEL was the native name of the city called Babylon by the Greeks. It means "gate of god," or "gate of the gods," and was the Semitic translation of the original Accadian designation Ca-dimirra. According to Gen. xi. 1–9, mankind, after the deluge, travelled from the mountain of the East (or Elwand), where the ark had rested, and settled in Shinar (Sumir, or the north-west of Chaldea). Here they attempted to build a city and a tower whose top might reach unto heaven, but were miraculously prevented by their language being confounded. In this way the diversity of human speech was accounted for; and an etymology was found for the name of Babylon in the Hebrew verb *balbel*, "to confound." According to Alexander Polyhistor (frg. 10) and Abydenus (frgs. 5 and 6), the tower was overthrown by the winds. The native version of the story has recently been discovered among the cuneiform

tablets in the British Museum. It is fuller and more complete than the account in Genesis, and formed part of a collection of Babylonian legends older, probably, than 2000 B.C. We learn from it that the tower was erected under the supervision of a semi-divine being called Etanna. The tower has been identified with the temple or tomb of Belus, which Strabo stated with some exaggeration to have been a stade (606 feet) high, but without sufficient reason. It is most probably represented by the modern *Birs Nimrud*, the ruined remains of the "Temple of the Seven Lights of the Earth," at Borsippa, a suburb of Babylon, which was dedicated to Nebo. The temple had been begun by "a former king," and built to the height of 42 cubits, but it lay an uncompleted ruin for many centuries, and was not finished till the reign of Nebuchadnezzar. Dr Schrader believes that the state of wreck in which it so long remained caused "the legend of the confusion of tongues" to be attached to it. The earliest buildings met with in Chaldea are constructed of sun-dried brick and mud. A similar tradition to that of the tower of Babel is found in Central America. Xelhua, one of the seven giants rescued from the deluge, built the great pyramid of Cholula in order to storm heaven. The gods, however, destroyed it with fire and confounded the language of the builders. Traces of a somewhat similar story have also been met with among the Mongolian Tharus in Northern India (*Report of the Census of Bengal*, 1872, p. 160), and, according to Dr Livingstone, among the Africans of Lake Ngami. The Esthonian myth of "the Cooking of Languages" (Kohl, *Reisen in die Ostseeprovinzen*, ii. 251-255) may also be compared, as well as the Australian legend of the origin of the diversity of speech (Gerstäcker, *Reisen*, vol. iv. p. 381, *seq.*). See further the articles BABYLON and BABYLONIA. (A. H. S.)

BAB-EL-MANDEB, that is, the Gate of Tears, is the strait between Arabia and Abyssinia which connects the Red Sea with the Indian Ocean. It derives its name from the dangers attending its navigation, or, according to an Arabic legend, from the numbers who were drowned by the earthquake which separated Asia and Africa. The distance across is about 20 miles, from Ras Menheli on the Arabian coast to Ras Seyan on the African. The island of Perim, a black and desolate rock, about 4½ miles long by 2 broad, and rising to a height of 240 feet, divides the strait into two channels, of which the eastern and most frequented, known as the Bab Iskender (*Alexander's Strait*), is not more than 4 miles wide, and varies in depth from 7 to 14 fathoms, while the western, or Dact-el-Mayun, has a width of about 15 miles and a depth of 180 fathoms. Near the African coast lie a group of smaller islands known as the Seven Brothers. There is usually a surface outflow from the Red Sea, but a strong under-current must set inwards to compensate not only for this, but for the loss occasioned by the great evaporation. (See Carpenter's "Further Inquiries" in *J. R. Geog. S.*, 1874.) In the end of the 18th century (1799) the island of Perim was taken possession of by the British and held as a military outpost, so to speak, of the Indian empire. They again asserted their right to it in 1857, and in 1861 a lighthouse was built at Straits Point, at the eastern extremity of the island. The harbour is accessible and commodious, and the position gives complete command of the Red Sea.

BABER, ZEHIR-ED-DÎN MAHOMET, surnamed Baber, or the Tiger, the famous conqueror of India and founder of the so-called Moghul dynasty, was born on the 14th February 1483. He was a descendant of Genghis Khan and Timur, and his father, Omar Sheikh, was king of Farghana, a district of Transoxiana, lying east of Samarcand. Omar died in 1495, and Baber, though only twelve years of age, succeeded to the throne. An attempt made by his uncles to dislodge him proved unsuccessful, and no sooner was the young sovereign firmly settled than he began to meditate an extension of his own dominions. In 1497 he attacked and gained possession of Samarcand, to which he always seems to have thought he had a natural and hereditary right. A rebellion among his nobles robbed him of his native kingdom, and while marching to recover it, his troops deserted him, and he lost Samarcand also. After some reverses he regained both these places, but in 1501 his most formidable enemy, Schaibani Khan, ruler of the Usbeks, defeated him in a great engagement, and drove him from Samarcand. For three years he wandered about trying in vain to recover his lost possessions; at last, in 1504, he gathered some troops, and crossing the snowy Hindu Kush, besieged and captured the strong city of Cabul. By this dexterous stroke he gained a new and wealthy kingdom, and completely re-established his fortunes. In the following year he united with Hussain Mirza of Herat against Schaibani. The death of Hussain put a stop to this expedition, but Baber spent a year at Herat, enjoying the pleasures of that capital. He returned to Cabul in time to quell a formidable rebellion, but two years later a revolt among some of the leading Moghuls drove him from his city. He was compelled to take to flight, with very few companions, but his great personal courage and daring struck the army of his opponents with such dismay that they again returned to their allegiance, and Baber regained his kingdom. Once again, in 1510, after the death of Schaibani, he endeavoured to obtain possession of his native country. He received considerable aid from Shah Ismael of Persia, and in 1511 made a triumphal entry into Samarcand. But in 1514 he was utterly defeated by the Usbeks, and with difficulty reached Cabul. He seems now to have resigned all hopes of recovering Farghana, and as he at the same time dreaded an invasion of the Usbeks from the west, his attention was more and more drawn towards India. Several preliminary incursions had been already made, when in 1521 an opportunity presented itself for a more extended expedition. Ibrahim, emperor of Delhi, had made himself detested, even by his Afghan nobles, several of whom called upon Baber for assistance. He at once assembled his forces, 12,000 strong, with some pieces of artillery, and marched into India. Ibrahim, with 100,000 soldiers and numerous elephants, advanced against him. The great battle was fought at Paniput, 21st April 1526, when Ibrahim was slain and his army routed. Baber at once took possession of Agra. A still more formidable enemy awaited him; the Rana Sanga of Mewar collected the enormous force of 210,000 men, with which he moved against the invaders. On all sides there was danger and revolt; even Baber's own soldiers, worn out with the heat of this new climate, longed for Cabul. By vigorous measures and inspiriting speeches, he restored their courage, though his own heart was nearly failing him, and in his distress he abjured the use of wine, to which he had been addicted. At Kanweh, on the 10th March 1527, he won a great victory, and made himself absolute master of India. The remaining years of his life he spent in arranging the affairs and revenues of his new empire and in improving his capital, Agra. He died 26th December 1530, in his forty-eighth year. Baber was above the middle height, of great strength, and an admirable archer and swordsman. His mind was as well cultivated as his bodily powers; he wrote well, and his observations are generally acute and accurate; he was brave, kindly, and generous. Full materials for his life are found in his *Memoirs*, written by himself (translated into English by Leyden and Erskine, London, 1826; abridged in Caldecott, *Life of Baber*, London, 1844).

BABEUF, FRANÇOIS-NOEL, surnamed by himself

Gracchus Babeuf, the earliest of the French socialists, was born in 1762, in the department of Aisne. From his father, a major in the Austrian army, he received special instruction in mathematics, but was deprived of him by death at the age of sixteen. Established as a land-surveyor at Roye, in the Somme department, he became a fervid advocate of the Revolution, and wrote articles in the *Correspondant Picard*, for which he was prosecuted in 1790. He was acquitted on that occasion, and was afterwards elected an administrator of the department; but a charge of forgery being brought against him, he was condemned by the Somme tribunal to twenty years' imprisonment in 1793. Escaping to Paris, he became secretary to the Relief Committee of the Commune, and joined Garin in his denunciation of the Committee of Public Safety. This led to his incarceration, ostensibly under the former sentence. This was, however, annulled by the Court of Cassation; and he was also discharged by the Aisne tribunal (18th July 1794), to which he had been remitted. Returning to Paris, he entered on a violent crusade against the remains of the Robespierre party, and started the *Journal de la Liberté de la Presse* to maintain his views. In the following year (1795) the Girondists acquired supremacy in the Convention; Babeuf's journal was suspended, and himself imprisoned—first in Paris and then at Arras. Thrown into the society of certain partisans of Robespierre, he was won over by them, and was ready, on his release, to become the indiscriminating defender of the very men whom he had previously attacked (No. 34 of the *Tribun*, as he now called his journal). In April 1796 Babeuf, Lepelletier, and others constituted themselves a "Secret Directory of Public Safety," and took the title of the "Equals;" while another association of self-styled "Conventionals" and "Patriots" met at the house of Amar. The latter party aimed at the re-establishment of the revolutionary government, while Babeuf and his friends wanted besides to realise their schemes for the organisation of common happiness. Disputes naturally arose; and to reconcile the Equals and the Patriots, it was agreed, first, to re-establish the constitution of 1793; and secondly, to prepare for the adoption of true equality by the destruction of the Government. Everything was ready by the beginning of May 1796, and the number of adherents in Paris was reckoned at 17,000; but on the 10th the Government succeeded in arresting the main leaders of the plot. The army protected the Government, and the people of Paris looked on. The trial was opened at Vendôme on Feb. 2, 1797, and lasted three months. Babeuf and Darthé were sentenced to death; Germain, Buonarroti, and five others, to transportation; Amar, Vadier, Duplay, and the remaining fifty-three, were acquitted. On the announcement of the sentence, Babeuf and Darthé stabbed themselves, but the wounds were not mortal. They passed a frightful night, and next morning were borne bleeding to the scaffold. Ardent and generous, heroic and self-sacrificing, Babeuf had neither solid knowledge nor steadiness of judgment. "The aim of society is happiness, and happiness consists in equality," is the centre of his doctrine. Propagated under the name of Babouvism, it became the germ of contemporary communism. Babeuf's influence was fatal in a threefold way,—because he re-established the memory of Robespierre among French Republicans, connected them with the theories of Rousseau, and paved the way for that school of Socialists which left the lessons of experience and observation for Utopian dreams.

Babeuf's works are—1. *Cadastre perpétuel*, dédié à l'Assemblée Nationale, à Paris, l'an 1789 et le premier de la Liberté Française, in 8vo; 2. *Journal de la Liberté de la Presse*, which appeared from the 23d No. under the title of "*Le tribun du peuple*," styled by Michelet "le monument le plus instructif de l'époque;" 3. *Du Système de Dépopulation, ou la vie et les crimes de Carrier*, par Gracchus Babeuf, Paris, an III, in 8vo. See also, in addition to legal documents and the histories of the time, Buonarroti's *Histoire de la Conspiration de Babeuf*, of which there is an English translation by Bronterre, London, 1836.

BÂBI, or BÂBY, the appellation of a remarkable modern sect in Persia, is derived from the title (*bâb*, *i.e.*, gate) assumed by its founder, Seyed Mohammed Ali, born at Shiraz about 1824, according to Count Gobineau, but ten years earlier according to Kasem Beg. Persia, as is well known, is the least strictly Mahometan of all Mahometan countries, the prophet himself occupying an almost secondary place in the popular estimation to his successor Ali, and the latter's sons, Hassan and Hosein. The cause of this heterodoxy is, no doubt, to be sought in ethnological distinctions, the Aryan Persians never having been able to thoroughly accommodate themselves to the creed of their Semitic conquerors. Their dissatisfaction has found vent partly in the universal homage paid to Ali, and the rejection of the Sunna or great mass of orthodox Mahometan tradition, partly in violent occasional outbreaks, most characteristically of all in the mystical philosophy and poetry of the Sufis, which, under the guise of a profound respect for the externals of Mahometanism, dissolves its rigid Monotheism into Pantheism. Bâbism is essentially one of the innumerable schools of Sufism, directed into a more practical channel by its founder's keen perception of the evils of his times. His first appearance in public took place about 1843, when, on his return from a pilgrimage to Mecca and after a prolonged course of meditation in the ruined mosque of Kufa, the scene of Ali's murder, he presented himself in his native city with a journal of his pilgrimage and a new commentary on the Koran. He speedily became engaged in controversy with the mollahs or regular clergy, who, exasperated by the freedom of his strictures on their lives as well as their doctrines, obtained an official decree forbidding him to preach in public, and confining him to his house. The Bâb, by which title he was now universally known, complied in appearance, but continued to instruct his disciples in private; his doctrines rapidly assumed more logical consistency, and his pretensions augmented in an equal ratio. He now laid aside the title of Bâb, declaring himself to be the *Nokteh* or Point, *i.e.*, not merely the recipient of a new divine revelation, but the focus to which all preceding dispensations converged. There was little in such a pretension to shock Oriental habits of thought; while the simplicity and elevation of the ethical part of the Bâb's system, united to the charm of his manner and the eloquence of his discourse, rapidly gained fresh proselytes. The most remarkable of these was the Mollah Hussein Boushrevieh, a man of great erudition and energy of character, who, having come all the way from Khorassan to hear him, became his convert, and undertook the dissemination of his religion throughout the empire. Two other apostles were speedily added, the appearance of one of whom may almost be said to mark an epoch in Oriental life. It is rare indeed to find a woman enacting any distinguished part in the East, least of all that of a public teacher. Such, however, was the part assumed by the gifted Zerryn Taj (*Crown of Gold*), better known by the appellation of Gourred-Oul-Ayn (*Consolation of the Eyes*), bestowed in admiration of her surpassing loveliness. The third missionary was Mohammed Ali Balfouroushi, a religious man, who had already acquired a high reputation for sanctity. The new religion made rapid progress, and the endeavours of the authorities to repress it eventually produced a civil war. Hussein constructed a fort in the province of Mazanderan, where he defeated several expeditions despatched against him, but at length fell mortally wounded in the moment of victory, and his followers, reduced to surrender by famine, were mostly put to death (1849). Balfou-

roushi, with a number of his principal adherents, perished in the city of Zendian after an obstinate defence (May 1850). Ere this event had taken place, the Government had proceeded to the execution of the Bâb himself, who had now been confined for some time in the fortress of Cherigh, where he is said to have greatly impressed his gaolers by his patience and dignity. He was removed to Tabriz, and all attempts to induce him to retract having failed, he was suspended from the summit of a wall by the armpits in view of the people, along with one of his disciples; the object of this public exposure being to leave no doubt of the reality of his death. A company of soldiers discharged their muskets at the martyrs; but although the disciple was killed on the spot, the bullets merely cut the cords by which the Bâb himself was suspended, and he fell to the ground unhurt. With more presence of mind on his part, this apparently miraculous deliverance might have provoked a popular insurrection in his favour; but, bewildered by the fall, instead of invoking the people, he took refuge in a guard-house, where he was promptly despatched. His death was far from discouraging his followers, who recognised as his successor Mirza Yahya, a youth of noble birth. Yahya established himself at Baghdad, where he is or was recently still residing. No new event of importance occurred until 1852, when an attempt of several Bâbis to assassinate the Shah led to a ferocious persecution, in which the beautiful Gourred-Oul-Ayn perished with many others. In the opinion of M. Gobineau, this persecution has rather tended to encourage than to repress the sect, which is believed to be widely diffused in Persia at this moment, under the mask of conformity to the established creed. It can only be regarded as an individual symptom of a constantly recurring phenomenon—the essential incompatibility between the religious conceptions of Aryan and Semitic races. The doctrines of Bâbism are contained in an Arabic treatise, entitled *Biyan* (the Exposition), written by the Bâb himself. It is essentially a system of Pantheism, with additions from Gnostic, Cabbalistic, and even Buddhistic sources. All individual existence is regarded as an emanation from the Supreme Deity, by whom it will ultimately be reabsorbed. Great importance is attached to the number seven, being that of the attributes supposed to be displayed in the act of creation, and to the number nineteen, which mystically expresses the name of the Deity himself, and is, moreover, the sum of the prophets among whom the latest incarnation of the divine nature is conceived to be distributed in the present dispensation. Of these the Bâb is chief, but the other eighteen are regarded as no less participators in the divine nature. This sacred college cannot become extinct until the last judgment; the death of any of its members being immediately followed by a reincarnation, as in the case of the Grand Lama. The prophetic character of Moses, Christ, and Mahomet is acknowledged, but they are considered as mere precursors of the Bâb. The morality of the sect is pure and cheerful, and it manifests an important advance upon all previous Oriental systems in its treatment of woman. Polygamy and concubinage are forbidden, the veil is disused, and the equality of the sexes so thoroughly recognised that one at least of the nineteen sovereign prophets must always be a female. The other chief precepts of Bâbism inculcate hospitality, charity, and generous living, tempered by abstinence from intoxicating liquors and drugs. Asceticism is entirely discountenanced, and mendicancy, being regarded as a form of it, is strictly prohibited.

Our principal authorities on Bâbism to this date are Count Gobineau, formerly French *attaché* at Teheran, in his work, *Les Religions et les Philosophies dans l'Asie centrale* (Paris, 1865), and an article by Kasem Beg in the *Journal Asiatique* for 1866. These materials have been condensed into a valuable essay, by F. Pillon, in *L'Année Philosophique* for 1869. See also the *History of Persia under the Kajar Dynasty*, by R. G. Watson (whose accusations of immorality against the Bâbis seem to be founded solely on the misconduct of particular members of the sect); Ethé, *Essays und Studien* (Berlin, 1872); and incidental notices in the travels of Vambéry, Polak, Piggott, and Lady Sheil. (R. G.)

BABOON, the popular name of apes belonging to the genus *Cynocephalus* of the family *Simiadæ*. See APE, vol. ii. p. 152.

BABRIUS, or BABRIAS, or GABRIAS (the original name being possibly Oriental), a Greek fabulist, who wrote, according to Sir G. C. Lewis, shortly before the Augustan age, though dates have been assigned to him from 250 B.C. to 250 A.D. One of his editors, Boissonade, believes that he was a Roman. His name occurs in some of the old grammarians, and a few fragments were ascribed to him. The first critic who made him more than a mere name, was Bentley in his *Dissertation on the Fables of Æsop*. In a careful examination of these prose Æsopian fables, which had been handed down in various collections from the time of Maximus Planudes, Bentley discovered traces of versification, and was able to extract a number of verses which he assigned to Babrius. Tyrwhitt followed up the researches of Bentley, and for some time the efforts of scholars were directed towards reconstructing the metrical original of the prose fables. In 1842, however, M. Mynas, a Greek, the discoverer of the *Philosophoumena* of Hippolytus, came upon a MS. of Babrius in the convent of St Laura on Mount Athos. This MS. contained 123 fables out of the supposed original number, 160. The fables are written in choliambic, *i.e.*, limping or imperfect iambic verse, having a spondee as the last foot, a metre originally appropriated to satire. The style is extremely good, the expression being terse, pointed, and elegant, and the construction of the stories is fully equal to that in the prose versions. The MS. was first published by Boissonade in 1844; afterwards by Lachmann, 1845; by Orelli and Baiter, 1845; by Sir George Cornewall Lewis, 1846; and by Schneidewin, 1853. The genuineness of this collection of the fables was generally admitted by scholars. In 1857 Mynas professed to have discovered at Mount Athos another part containing 94 fables and a proœmium. According to his statement, the monks, who had been willing to sell the MS. containing the first part for a sufficient price, refused altogether to part with the second. He therefore made a copy which was sold to the British Museum, and was published in 1859 by Sir G. C. Lewis. But these fables only purport to be Babrius spoiled, after having passed through the hands of a "diasceuast," that is, some late writer who has turned his verses into barbarous Greek and wretched metre. In a Latin dissertation, published in 1861, Professor Conington carefully examined this part, arriving at the conclusion that the fables were metrical versions of the prose stories, executed by some forger who must have been acquainted with Lachmann's conjectures on fragments formerly known. Cobet expresses a similar opinion, but in stronger terms. It is not impossible that the forger was Mynas himself. Sir G. C. Lewis, however, holds that the similarity between the fables and these existing prose versions appears such as might have been produced not by a forger copying from a prose writer, but rather by two grammarians recasting the same work of Babrius. The standard edition of Babrius is that of Sir G. C. Lewis; there is a faithful translation in verse by Davies. For Conington's dissertation see his *Miscellaneous Writings*, vol. ii. pp. 460-491.

BABYLON—BABYLONIA

BABYLON (the modern *Hillah*) is the Greek form of Babel or Bab-ili, "the gate of god" (or, as it is sometimes written, "of the gods"), which, again, is the Semitic rendering of *Ca-dimirra*, the ancient name of the city in the Turanian language of the primitive Accadian population of the country. It is doubtful whether the god meant was Merodach or Anu, Merodach being the patron divinity of Babylon in the Semitic period, and Su-Anna, "the valley of Anu" (Anammelech), being one of its oldest names. Another synonym of the place was *E-ci*, "the hollow," in reference to its situation, and it was also known, down to the latest times, as Din-Tir, "the house of the jungle," though this seems properly to have been the designation of the town on the left bank of the Euphrates. Under the Cassite dynasty of Khammuragas, it received the title of Gan-Duniyas or Gun-Duni, "the Fortress of Duniyas," which was afterwards made to include the neighbouring territory, so that the whole of Babylonia came to be called by this name. Sir H. Rawlinson has suggested that it was the origin of the Biblical Gan Eden, or "Garden of Eden," to which a popular etymology has given a Hebrew form. However this may be, Babylon figures in the antediluvian history of Berosus, the first of his mythical monarchs, Alorus, being a native of it. The national epic of the Babylonians, which grouped various old myths round the adventures of a solar hero, knows of four cities only—Babylon, Erech, Nipur (*Niffer*) or Calneh, and Surippac or Larankha; and according to Genesis x., Babylon was a member of the tetrapolis of Shinar or Sumir, where the Semite invaders of the Accadians first obtained permanent settlement and power. It seems, however, to have ranked below its three sister-cities, among which Erech took the lead until conquered by the Accadian sovereigns of Ur. It was not until the conquest of Khammuragas that Babylon became a capital, a position, however, which it never afterwards lost, except during the Assyrian supremacy. But it suffered severely at the hands of its northern neighbours. Tiglath-Adar drove the Cassi from it, and established an Assyrian dynasty in their place; and after being captured by Tiglath-Pileser I. (1130 B.C.) and Shalmaneser (851 B.C.), it became a dependency of the Assyrian empire in the reign of the son of the latter. The decline of the first Assyrian empire restored Babylon to independence; but it had soon afterwards to submit to the Caldai, and from the reign of Tiglath-Pileser II. to the death of Assur-banipal, it was a mere provincial town of Assyria, breaking now and then into fierce revolt under the leadership of the Caldai, and repeatedly taken and plundered by Sargon, Sennacherib, and Assur-bani-pal. Sennacherib, indeed, razed the city to its foundations. After the defeat of Suzub (690 B.C.), he tells us that he "pulled down, dug up, and burned with fire the town and the palaces, root and branch, destroyed the fortress and the double wall, the temples of the gods and the towers of brick, and threw the rubbish into the Araxes," the river of Babylon. After this destruction it is not likely that much will ever be discovered on the site of Babylon older than the buildings of Essar-haddon and Nebuchadnezzar. It was under the latter monarch and his successors that Babylon became the huge metropolis whose ruins still astonish the traveller, and which was described by Greek writers. Of the older city we can know but little. The Babylon of Nebuchadnezzar and his father, Nabopolassar, must have suffered when taken by Cyrus; but two sieges in the reign of Darius Hystaspis, and one in the reign of Xerxes, brought about the destruction of the defences, while the monotheistic rule of Persia allowed the temples to fall into decay. Alexander found the great temple of Bel a shapeless ruin, and the rise of Seleucia in its neighbourhood drew away its population and completed its material decay. The buildings became a quarry, first for Seleucia and then for Ctesiphon, Al Modain, Baghdad, Kufa, Kerbelah, Hillah, and other towns, and our only cause for wonder is that the remains of the great capital of Babylonia are still so extensive.

The principal of these lie on the left bank of the Euphrates, and consist of three vast mounds—the *Babil* or *Mujellibe*, the *Kasr*, and the *Amrám*, which run from north to south; two parallel lines of rampart east and west of them; and an isolated mass, together with a series of elevations separated by the river westward of the *Kasr*,—the whole being surrounded by a triangular rampart. Our two chief authorities for the ancient topography of the city are Herodotus and Ctesias; and though both were eye-witnesses, their statements differ considerably. The city was built, we are told, on both sides of the river, in the form of a square, and enclosed within a double row of high walls. Ctesias adds a third wall, but the inscriptions refer only to two, the inner *enceinte*, called Imgur-Bel, and its *salkhu* or outwork, called Nimitti-Bel. Ctesias makes the outermost wall 360 stades (42 miles) in circumference, while according to Herodotus it measured 480 stades (56 miles), which would include an area of about 200 square miles! Pliny (*N. H.*, vi. 26) follows Herodotus in his figures, but Strabo (xvi. 1, 5) with his 385 stades, Qu. Curtius (v, 1, 26) with his 368 stades, and Clitarchus (ap. Diod. Sic., ii. 7) with 365 stades, agree sufficiently closely with Ctesias. Even the estimate of Ctesias, however, would make Babylon cover a space of about 100 square miles, nearly five times the size of London. Such an area could not have been occupied by houses, especially as these were three or four stories high (Hdt., i. 180). Indeed Q. Curtius asserts (v. 1, 27) that even in the most flourishing times, nine-tenths of it consisted of gardens, parks, fields, and orchards. According to Herodotus, the height of the walls was about 335 feet, and their width 85 feet; while Ctesias makes the height about 300 feet. Later writers give smaller dimensions, but it is clear that they have merely tried to soften down the estimates of Herodotus (and Ctesias); and we seem bound, therefore, to accept the statement of the two oldest eye-witnesses, astonishing as it is. But we may remember that the ruined wall of Nineveh was 150 feet high, even in Xenophon's time (*Anab.*, iii. 4, 10, and *cf.* ii. 4, 12), while the spaces between the 250 towers irregularly disposed along the wall of Babylon (Ctes. ap. Diod., ii. 7) were broad enough to allow a four-horse chariot to turn (Hdt., i. 179). The clay dug from the moat had served for the bricks of the wall, which was pierced with 100 gates, all of brass, with brazen lintels and posts. The two inner enclosures were faced with coloured brick, and represented hunting-scenes. Two other walls ran along the banks of the Euphrates and the quays with which it was lined, each containing 25 gates, which answered to the number of the streets they led into. Ferry-boats plied between the landing-places of the gates; and a movable drawbridge (30 feet broad), supported on stone piers, joined the two parts of the city together. At each end of the bridge was a palace; the great palace of Nebuchadnezzar on the eastern side (the modern *Kasr*), which Herodotus incorrectly transfers to the western bank, being the most magnificent of the two. It was surrounded, according to Diodorus (ii. 8, 4), by three

walls, the outermost being 60 stades (7 miles) in circuit. The inner walls were decorated with hunting-scenes painted on brick, fragments of which have been discovered by modern explorers. Two of its gates were of brass, and had to be opened and shut by a machine; and Mr Smith has found traces of two libraries among its ruins. The palace, called "the Admiration of Mankind" by Nebuchadnezzar, and commenced by Nabopolassar, overlooked the Ai-ipur-sabu, the great reservoir of Babylon, and stretched from this to the Euphrates on the one side, and from the Imgur-Bel, or inner wall, to the Libil, or eastern canal, on the other. Within its precincts rose the Hanging Gardens, consisting of a garden of trees and flowers on the topmost of a series of arches at least 75 feet high, and built in the form of a square, each side measuring 400 Greek feet. Water was raised from the Euphrates by means, it is said, of a screw (Strab., xvi. 1, 5; Diod., ii. 10, 6). Some of the materials for the construction of this building may have been obtained from the old ruined palace of the early kings, now represented by the adjoining Amrám mound. The lesser palace in the western division of the city belonged to Neriglissar, and contained a number of bronze statues.

The most remarkable edifice in Babylon was the temple of Bel, now marked by the *Babîl*, on the north-east, as Professor Rawlinson has shown. It was a pyramid of eight square stages, the basement stage being over 200 yards each way. A winding ascent led to the summit and the shrine, in which stood a golden image of Bel 40 feet high, two other statues of gold, a golden table 40 feet long and 15 feet broad, and many other colossal objects of the same precious material. At the base of the tower was a second shrine, with a table and two images of solid gold. Two altars were placed outside the chapel, the smaller one being of the same metal. A similar temple, represented by the modern *Birs Nimrud*, stood at Borsippa, the suburb of Babylon. It consisted of seven stages, each ornamented with one of the seven planetary colours, the azure tint of the sixth, the sphere of Mercury, being produced by the vitrifaction of the bricks after the stage had been completed. The lowest stage was a square, 272 feet each way, its four corners exactly corresponding to the four cardinal points, as in all other Chaldean temples, and each of the square stages raised upon it being placed nearer the south-western than the north-eastern edge of the underlying one. It had been partly built by an ancient monarch, but, after lying unfinished for many years, like the Biblical tower of Babel, was finally completed by Nebuchadnezzar.

The amount of labour bestowed upon these brick edifices must have been enormous, and gives some idea of the human force at the disposal of the monarch. If any further illustration of this fact were needed, it would be found in the statement made by Nebuchadnezzar in one of his inscriptions (and quoted also from Berosus), that he had finished the Imgur-Bel in fifteen days. The same monarch also continued the embankment of the Euphrates for a considerable distance beyond the limits of Babylon, and cut some canals to carry off the overflow of that river into the Tigris. The great reservoir, 40 miles square, on the west of Borsippa, which had been excavated to receive the waters of the Euphrates while the bed of its channel was being lined with brick, was also used for a similar purpose. The reservoir seems to have been entered by the Arakhtu or Araxes, "the river of Babylon," which flowed through a deep wady into the heart of Northern Arabia, as Wetzstein has pointed out. Various nomad tribes, such as the Nabathæans or the Pekod, pitched their tents on its banks; but, although it is not unfrequently mentioned in early Babylonian history, we hear no more of it after the time of Nebuchadnezzar. It is possible, therefore, that it was drained by the western reservoir. (A. H. S.)

BABYLONIA AND ASSYRIA. Geographically, as well as ethnologically and historically, the whole district enclosed between the two great rivers of Western Asia, the Tigris and Euphrates, forms but one country. The writers of antiquity clearly recognised this fact, speaking of the whole under the general name of Assyria, though Babylonia, as will be seen, would have been a more accurate designation. It naturally falls into two divisions, the northern being more or less mountainous, while the southern is flat and marshy; and the near approach of the two rivers to one another, at a spot where the undulating plateau of the north sinks suddenly into the Babylonian alluvium, tends still more completely to separate them. In the earliest times of which we have any record, the northern portion was comprehended under the vague title of Gutium (the *Goyim* of Gen. xiv. 1), which stretched from the Euphrates on the west to the mountains of Media on the east; but it was definitely marked off as Assyria after the rise of that monarchy in the 16th century B.C. Aram-Naharaim, or Mesopotamia, however, though claimed by the Assyrian kings, and from time to time overrun by them, did not form an integral part of the kingdom until the 9th century B.C., while the region on the left bank of the Tigris, between that river and the Greater Zab, was not only included in Assyria, but contained the chief capitals of the empire. In this respect the monarchy of the Tigris resembled Chaldea, where some of the most important cities were situated on the Arabian side of the Euphrates. The reason of this preference for the eastern bank of the Tigris was due to its abundant supply of water, whereas the great Mesopotamian plain on the western side had to depend upon the streams which flowed into the Euphrates. This vast flat, the modern El-Jezireh, is about 250 miles in length, interrupted only by a single limestone range, rising abruptly out of the plain, and branching off from the Zagros mountains under the names of *Sarazûr*, *Hamrin*, and *Sinjar*. The numerous remains of old habitations show how thickly this level tract must once have been peopled, though now for the most part a wilderness. North of the plateau rises a well-watered and undulating belt of country, into which run low ranges of limestone hills, sometimes arid, sometimes covered with dwarf-oak, and often shutting in, between their northern and north-eastern flank and the main mountain-line from which they detach themselves, rich plains and fertile valleys. Behind them tower the massive ridges of the Niphates and Zagros ranges, where the Tigris and Euphrates take their rise, and which cut off Assyria from Armenia and Kurdistan. The name Assyria itself originally denoted the small territory immediately surrounding the primitive capital "the city of Asur" (*al Asur*, the Ellasar of Genesis), which was built, like the other chief cities of the country, by Turanian tribes, in whose language the word signified "water-meadow." It stood on the right bank of the Tigris, midway between the Greater and the Lesser Zab, and is represented by the modern *Kalah Sherghat*. It remained the capital long after the Assyrians had become the dominant power in Western Asia, but was finally supplanted by Calah (*Nimrûd*), Nineveh (*Nebi Yunus* and *Kouyunjik*), and Dur-Sargina (*Khorsabad*), some 60 miles further north. See NINEVEH.

In contrast with the arid plateau of Mesopotamia, stretched the rich alluvial plain of Chaldea, formed by the deposits of the two great rivers by which it was enclosed. The soil was extremely fertile, and teemed with an industrious population. Eastward rose the mountains of Elam, southward were the sea-marshes, and the ancient kingdom of Nituk or Dilvun (the modern Bender-Dilvun), while on the west the civilisation of Babylonia encroached beyond the banks of the Euphrates, upon the territory of the Semitic nomades (or Suti). Here stood Ur (now

Mugheir), the earliest capital of the country; and Babylon, with its suburb, Borsippa (*Birs Nimrûd*), as well as the two Sipparas (the Sepharvaim of Scripture, now *Mosaib*), occupied both the Arabian and Chaldean side of the river. (See BABYLON.) The Araxes, or "River of Babylon," was conducted through a deep valley into the heart of Arabia, irrigating the land through which it passed; and to the south of it lay the great inland fresh-water sea of *Nedjef*, surrounded by red sandstone cliffs of considerable height, 40 miles in length and 35 in breadth in the widest part. Above and below this sea, from Borsippa to Kufa, extend the famous Chaldean marshes, where Alexander was nearly lost (Arrian, *Exp. Al.*, vii. 22; Strab., xvi. 1, § 12); but these depend upon the state of the Hindiyah canal, disappearing altogether when it is closed. Between the sea of *Nedjef* and Ur, but on the left side of the Euphrates, was Erech (now *Warka*), which with Nipur or Calneh (now *Niffer*), Surippac (*Senkereh?*), and Babylon (now *Hillah*), formed the tetrapolis of Sumir or Shinar. This north-western part of Chaldea was also called Gan-duniyas or Gun-duni after the accession of the Cassite dynasty. South-eastern Chaldea, on the other hand, was termed Accad, though the name came also to be applied to the whole of Babylonia. The Caldai, or Chaldeans, are first met with in the 9th century B.C. as a small tribe on the Persian Gulf, whence they slowly moved northwards, until under Merodach-Baladan they made themselves masters of Babylon, and henceforth formed so important an element in the population of the country, as in later days to give their name to the whole of it. In the inscriptions, however, Chaldea represents the marshes of the sea-coast, and Teredon was one of their ports. The whole territory was thickly studded with towns; but among all this "vast number of great cities," to use the words of Herodotus, Cuthah, or Tiggaba (now *Ibrahim*), Chilmad (*Kalwadah*), Is (*Hit*), and Dur-aba (*Akkerkuf*) alone need be mentioned. The cultivation of the country was regulated by canals, the three chief of which carried off the waters of the Euphrates towards the Tigris above Babylon,—the "Royal River," or Ar-Malcha, entering the Tigris a little below Baghdad, the Nahr-Malcha running across to the site of Seleucia, and the Nahr-Kutha passing through Ibrahim. The Pallacopas, on the other side of the Euphrates, supplied an immense lake in the neighbourhood of Borsippa. So great was the fertility of the soil that, according to Herodotus (i. 193), grain commonly returned two hundredfold to the sower, and occasionally three hundredfold. Pliny, too (*H. N.*, xviii. 17), says that wheat was cut twice, and afterwards was good keep for sheep; and Berosus remarked that wheat, barley, sesame, ochrys, palms, apples, and many kinds of shelled fruit grew wild, as wheat still does in the neighbourhood of Anah. A Persian poem celebrated the 360 uses of the palm (Strab., xvi. 1, 14), and Ammianus Marcellinus (xxiv. 3) states that from the point reached by Julian's army to the shores of the Persian Gulf was one continuous forest of verdure.

Such a country was well fitted to be one of the primeval seats of civilisation. Where brick lay ready to hand, and climate and soil needed only settled life and moderate labour to produce all that man required, it was natural that the great civilising power of Western Asia should take its rise. The history of the origin and development of this civilisation, interesting and important as it is, has but recently been made known to us by the decipherment of the native monuments. The scanty notices and conflicting statements of classical writers have been replaced by the evidence of contemporaneous documents; and though the materials are still but a tithe of what we may hope hereafter to obtain, we can sketch the outlines of the history, the art, and the science of the powerful nations of the Tigris and Euphrates. Before doing so, however, it would be well to say a few words in regard to our classical sources of information, the only ones hitherto available. The principal of these is Berosus, the Manetho of Babylonia, who flourished at the time of Alexander's conquests (though see Havet, *Mémoire sur la Date des Ecrits qui portent les noms de Bérose et de Manethon*). He was priest of Bel, and translated the records and astronomy of his nation into Greek. His works have unfortunately perished, but the second and third hand quotations from them, which we have in Eusebius and other writers, have been strikingly verified by inscriptions so far as regards their main facts. The story of the flood taken from Berosus, for instance, is almost identical with the one preserved on the cuneiform tablets. Numerical figures, however, as might be expected, are untrustworthy. According to Berosus, ten kings reigned before the Deluge for 120 *saroi*, or 432,000 years, beginning with Alorus of Babylon and ending with Otiartes (Opartes) of Larankha, and his son Sisuthrus, the hero of the flood. Then came eight dynasties, which are given as follows :—

(1.)	86 Chaldean kings		34,080	years.
(2.)	8 Median	,,	224	,,
(3.)	11 (Chaldean)	,,	*	
(4.)	49 Chaldean	,,	458	,,
(5.)	9 Arabian	,,	245	,,
(6.)	45 Assyrian	,,	526	,,
(7.)	* (Assyrian)	,,	*	
(8.)	6 Chaldean	,,	87	,,

Ptolemy's canon (in the *Almagest*) gives the seventh dynasty in full—

(1.)	Nabonassar (747 B.C.)	14	years.
(2.)	Nadios	2	,,
(3.)	Khinziros and Poros (Pul)	5	,,
(4.)	Ilulæos	5	,,
(5.)	Mardokempados (Merodach-Baladan)	12	,,
(6.)	Arkeanos (Sargon)	5	,,
(7.)	Interregnum	2	,,
(8.)	Hagisa	1	month.
(9.)	Belibos (702 B.C.)	3	years.
(10.)	Assaranadios (Assur-nadin-sum)	[illegible]	,,
(11.)	Rêgobelos	1	,,
(12.)	Mesêsimordakos	4	,,
(13.)	Interregnum	8	,,
(14.)	Asaridinos (Essar-haddon)	13	,,
(15.)	Saosdukhinos (Savul-sum-yucin)	20	,,
(16.)	Sinêladanos (Assur-bani-pal)	22	,,

Next to Berosus, the authority of Herodotus ranks highest. His information, however, is scanty, and he had to trust to the doubtful statements of *ciceroni*. Herodotus was controverted by Ctesias of Cnidus, the physician of Artaxerxes Mnemon. But Ctesias mistook mythology for history, and the Ninus and Semiramis, the Ninyas and Sardanapalus, of Greek romance were in great measure his creations. We may yet construct an Assyrian epopee, like the Shahnameh of Firdusi, out of his pages, but we must not look to them for history. Other historical notices of Assyria and Babylonia, of more or less questionable value, are to be gathered from Diodorus and one or two more writers, but beyond Berosus and, to a limited extent, Herodotus, our only ancient authority of much value upon this subject is the Old Testament.

Ethnology and History.—The primitive population of Babylonia, the builders of its cities, the originators of its culture, and the inventors of the cuneiform system of writing, or rather of the hieroglyphics out of which it gradually developed, belonged to the Turanian or Ural-Altaic family. Their language was highly agglutinative, approaching the modern Mongolian idioms in the simplicity of its grammatical machinery, but otherwise more nearly related to the Ugro-Bulgaric division of the Finnic group; and its speakers were mentally in no way inferior to the Hungarians and Turks of the present day. The country

was divided into two halves, the Sumir (Sungir, or Shinar) in the north-west, and the Accad in the south-east, corresponding most remarkably to the Suomi and Akkara-k, into which the Finnic race believed itself to have been separated in its first mountain home. Like Suomi, Sumir signified "(the people) of the rivers," and just as Finnic tradition makes Kemi a district of the Suomi, so Came was another name of the Babylonian Sumir. The Accadai, or Accad, were "the highlanders" who had descended from the mountainous region of Elam on the east, and it was to them that the Assyrians ascribed the origin of Chaldean civilisation and writing. They were, at all events, the dominant people in Babylonia at the time to which our earliest contemporaneous records reach back, although the Sumir, or "people of the home language," as they are sometimes termed, were named first in the royal titles out of respect to their prior settlement in the country. A survey of the syllabary has led to the conclusion that the first attempts at writing were made before the Accad had descended into the plains and exchanged papyrus as a writing material for clay; other considerations, however, go to show that although the system of writing may have been invented before they had entered Babylonia, it was not completed until after they had done so. In harmony with this, we find Berosus ascribing the culture of "the mixed population of Chaldea" to Oannes and other similar creatures from the Persian Gulf. So far as we can judge, the civilisation of Elam is at least coeval with that of Babylonia, and the capture of Babylon by the Medes, with whom the historical dynasties of Berosus are commonly supposed to begin, must be explained by an Elamite conquest. Media was the Accadian *Mada*, "the land" *par excellence;* and Accadian tradition looked back upon the mountainous district to the south-west of the Caspian as the cradle of their race. Among these "mountains of the east," and in the land of Nisir (the furthermost division of Gutium beyond the Lesser Zab), rose "the mountain of the world," the Turanian Olympus, on which the ark of the Chaldean Noah was believed to have rested. From this centre Turanian tribes spread in all directions, meeting Alarodians on the north, and Semites on the south-west. The Aryans had not yet penetrated across the great Sagartian desert. The numerous tribes of Susiana, both civilised and uncivilised, spoke languages more closely Ugrian than even that of the Accadians; the oldest towns of Northern Syria, where the Semite afterwards reigned supreme, bore Accadian names, and, as in the case of Haran, were mythologically connected with Babylon; while the chief cities of Assyria were founded by Accadians, were denoted by Accadian symbols, and were ruled by Accadian princes, in strict accordance with the statement of Genesis that out of Babylonia "went forth Asshur." An Elamite conqueror of Chaldea, like Chedorlaomer (Gen. xiv. 1), imposed his authority not only over Shinar, but over Assyria and Gutium as well. The earliest geographical lists know only of Nuvva, or Elam, on the east, the Khani on the west, Martu, the land of "the path of the setting sun," Subarti, or Syria, with its four races, and Gutium, which stretched across Mesopotamia from the Euphrates on the one side to the mountains of Media on the other. To these must be added Anzan, or southern Elam, with its capital Susa, Dilvun, or Nituk, on the Persian Gulf, and, at a considerably later date, the Hittites, with their chief city Carchemish.

The first monarchs whose monumental records we possess had their seat at Ur, on the right bank of the Euphrates. Ur, in Accadian, signified "the city" *par excellence*, and so bore testimony to the supremacy claimed by its rulers over the rest of Babylonia. The great temple of the Moon-god there was one of the oldest buildings in the country, and its erection was due to a prince who claimed sovereignty over the whole of Babylonia, and adorned Erech, Nipur, Larsa, and other cities with temples of vast size, dedicated to the sun, to Istar, and to Bel. He seems to have been the first great Babylonian builder; and this would imply that it was under him that Ur rose to its prominent position, and united the numerous principalities of Chaldea under one head. The enormous brick structures were cemented with bitumen in the place of lime mortar; but the use of the buttress, of drains, and of external ornamentation shows that architectural knowledge was already advanced. The cuneiform system of writing had attained its full development, signet stones were carved with artistic skill, and the amount of human force at the disposal of the monarch may be estimated from the fact that the Bowariyeh mound at Warka, on the site of the temple of the Sun-god, is 200 feet square and 100 feet high, so that above 30,000,000 bricks must have been employed upon its construction. The vicinity of Ur to the Semitic tribes of Arabia implies that the Accadian sovereigns had been turning their attention in that direction, and we find nothing surprising therefore in the Scriptural account of Abraham's migration from this place, or the Phœnician tradition of the original home of the Canaanitish race on the shores of the Persian Gulf (Strab., i. 2, 35, xvi. 3, 4, 27; Justin, xviii. 3, 2; Pliny, *N. H.*, iv. 36). Indeed, we have clear evidence that Semitic was spoken in Ur itself at this remote epoch. Although the ruling caste were Accadian, and generally wrote their inscriptions in that language, Dungi, one of their earliest monarchs, in spite of his Turanian name, has left us a short legend in Semitic; and it is more than probable that the imperial title of "Sumir and Accad" was soon to be assumed to mark a linguistic as well as a geographical distinction. The brick legends of the various viceroys who governed the cities of Chaldea under this dynasty are all, however, in Accadian.

The supremacy of Ur had been disputed by its more ancient rival Erech, but had finally to give way before the rise of Nisin or Karrak, a city whose site is uncertain, and Karrak in its turn was succeeded by Larsa. Elamite conquest seems to have had something to do with these transferences of the seat of power. In 2280 B.C.—the date is fixed by an inscription of Assur-bani-pal's—Cudur-nankhundi, the Elamite, conquered Chaldea at a time when princes with Semitic names appear to have been already reigning there, and Cudur-mabug not only overran "the west," or Palestine, but established a line of monarchs in Babylonia. His son and successor took an Accadian name, and extended his sway over the whole country. Twice did the Elamite tribe of Cassi or Kossæans furnish Chaldea with a succession of kings. At a very early period we find one of these Kossæan dynasties claiming homage from Syria, Gutium, and Northern Arabia, and rededicating the images of native Babylonian gods, which had been carried away in war, with great splendour and expense. The other Cassite dynasty was founded by Khammuragas, who established his capital at Babylon, which henceforward continued to be the seat of empire in the south. The dynasty is probably to be identified with that called Arabian by Berosus,[1] and it was during its domination that Semitic came gradually to supersede Accadian as the language of the country. Khammuragas himself assumed a Semitic name, and a Semitic inscription of his is now in the Louvre. A large number of canals were constructed during his reign, more especially the famous Nahr-Malcha, and an embankment built along the banks of the Tigris. The king's attention seems to have been turned to the subject of irrigation by a flood which overwhelmed the important city of Mullias. His

[1] If so, the number of reigns to be assigned to it, as well as its duration, will have to be corrected, as we know of at least nineteen kings belonging to this Cassite dynasty.

first conquests were in the north of Babylonia, and from this base of operations he succeeded in overthrowing Naram-Sin (or Rim-Acu?) in the south, and making himself master of the whole of Chaldea. Naram-Sin and a queen had been the last representatives of a dynasty which had attained a high degree of glory both in arms and in literature. Naram-Sin and his father Sargon had not only subdued the rival princes of Babylonia, but had successfully invaded Syria, Palestine, and even, as it would seem, Egypt. At Agane, a suburb of Sippara, Sargon had founded a library, especially famous for its works on astrology and astronomy, copies of which were made in later times for the libraries of Assyria. Indeed, so prominent a place did Sargon take in the early history of Babylonia, that his person became surrounded with an atmosphere of myth. Not only was he regarded as a sort of eponymous hero of literature, a Babylonian Solomon, whose title was "the deviser of law and prosperity," popular legends told of his mysterious birth, how, like Romulus and Arthur, he knew no father, but was born in secrecy, and placed by his mother in an ark of reeds and bitumen, and left to the care of the river; how, moreover, this second Moses was carried by the stream to the dwelling of a ferryman, who reared him as his own son, until at last the time came that his rank should be discovered, and Sargon, "the constituted king, for such is the meaning of his name, took his seat upon the throne of his ancestors. It was while the Cassite sovereigns were reigning in the south, and probably in consequence of reverses that they suffered at the hands of the Egyptians, who, under the monarchs of the 18th dynasty, were pushing eastward, that the kingdom of Assyria took its rise. Its princes soon began to treat with their southern neighbours on equal terms; the boundaries of the two kingdoms were settled, and intermarriages between the royal families took place, which led more than once to an interference on the part of the Assyrians in the affairs of Babylonia. Finally, in the 14th century B.C., Tiglath-Adar of Assyria captured Babylon, and established a Semitic line of sovereigns there, which continued until the days of the later Assyrian empire. From this time down to the destruction of Nineveh, Assyria remained the leading power of Western Asia. Occasionally, it is true, a king of Babylon succeeded in defeating his aggressive rival and invading Assyria; but the contrary was more usually the case, and the Assyrians grew more and more powerful at the expense of the weaker state, until at last Babylonia was reduced to a mere appanage of Assyria.

We possess an almost continuous list of Assyrian kings; and, as from the beginning of the 9th century downwards there exists a native canon, in which each year is dated by the *limmu* or *archon eponymos*, whose name it bears, as well as a portion of a larger canon which records the chief events of each eponymy, it is evident that our chronology of the later period of Assyrian history is at once full and trustworthy. Similar chronological lists once existed for the earlier period also, since an inscription of a king of the 14th century B.C. is dated by one of these eponymies; and the precise dates given in the inscriptions for occurrences which took place in the reigns of older monarchs cannot otherwise be accounted for. How far back an accurate chronological record extended it is impossible to say; but astronomical observations were made in Babylonia from a remote period, and the era of Cudur-nankhundi was known, as we have seen, more than 1600 years afterward; while in Assyria not only can Sennacherib state at Bavian that Tiglath-Pileser I. was defeated by the Babylonians 418 years before his own invasion of that country, but the same Tiglath-Pileser can fix 701 years as the exact interval between his restoration of the temple of Anu and Rimmon at Kalah Sherghat and its foundation by the dependent viceroys of the city of Assur.

This Tiglath-Pileser, in spite of his subsequent defeat by the Babylonians, was one of the most eminent of the sovereigns of the first Assyrian empire. He carried his arms far and wide, subjugating the Moschians, Comagenians, Urumians, and other tribes of the north, the Syrians and Hittites in the west, and the Babylonians (including their capital) in the south. His empire, accordingly, stretched from the Mediterranean on the one side to the Caspian and the Persian Gulf on the other; but, founded as it was on conquest, and centralised in the person of a single individual, it fell to pieces at the least touch. With the death of Tiglath-Pileser, Assyria seems to have been reduced to comparative powerlessness, and when next its claims to empire are realised, it is under Assur-natsir-pal, whose reign lasted from 883 to 858 B.C. The boundaries of his empire exceeded those of his predecessor, and the splendid palaces, temples, and other buildings raised by him, with their elaborate sculptures and rich paintings, bear witness to a high development of wealth and art and luxury. Calah, which had been founded by Shalmaneser I. some four or five centuries previously, but had fallen into decay, became his favourite residence, and was raised to the rank of a capital. His son Shalmaneser had a long reign of 35 years, during which he largely extended the empire he had received from his father. Armenia and the Parthians paid him tribute; and under the pretext of restoring the legitimate monarch he entered Babylon, and reduced the country to a state of vassalage. It is at this time that we first hear of the Caldai or Chaldeans,—carefully to be distinguished from the *Casdim* or Semitic "conquerors" of Scripture,—who formed a small but independent principality on the sea-coast. In the west Shalmaneser succeeded in defeating in 854 B.C. a dangerous confederacy, headed by Rimmon-idri or Ben-hadad of Damascus, and including Ahab of Israel and several Phœnician kings. Later on in his reign he again annihilated the forces of Hazael, Ben-hadad's successor, and extorted tribute from the princes of Palestine, among others from Jehu of Samaria, whose servants are depicted on the black obelisk. The last few years of his life, however, were troubled by the rebellion of his eldest son, which well-nigh proved fatal to the old king, Assur, Arbela, and other places joined the pretender, and the revolt was with difficulty put down by Shalmaneser's second son, Samas-Rimmon, who shortly after succeeded him. Samas-Rimmon (824–811) and Rimmon-nirari (811–782) preserved the empire of Assyria undiminished; but their principal exploits were in Babylonia, which they wasted with fire and sword, and converted into an Assyrian province.

The first Assyrian empire came to an end in 744, when the old dynasty was overthrown by a usurper, Tiglath-Pileser, after a struggle of three or four years. Once settled on the throne, however, Tiglath-Pileser proceeded to restore and reorganise the empire. Babylonia was first attacked; the Assyrian monarch offered sacrifices and set up his court in its chief cities; and the multitudinous Arab tribes who encamped along the banks of the Euphrates were reduced to subjection. The Caldai in the south alone held out, and to them belonged the first four kings given in Ptolemy's canon. Indeed, it may be said that from the invasion of Tiglath-Pileser to the revolt of Nabopolassar, Babylonia ceased to have any separate existence. It was governed by Assyrian kings or the viceroys they appointed, and the only attempts to recover independence were made under the leadership of the "Caldean" chiefs. It becomes nothing more than an important province of Assyria.

The second Assyrian empire differed from the first in its

greater consolidation. The conquered provinces were no longer loosely attached to the central power by the payment of tribute, and ready to refuse it as soon as the Assyrian armies were out of sight; they were changed into satrapies, each with its fixed taxes and military contingent. Assyrian viceroys were nominated wherever possible, and a turbulent population was deported to some distant locality. This will explain the condition in which Babylonia found itself, as well as the special attention which was paid to the countries on the Mediterranean coast. The possession of the barbarous and half-deserted districts on the east was of little profit; the inhabitants were hardy mountaineers, difficult to subdue, and without wealth; and although Tiglath-Pileser penetrated into Sagartia, Ariana, and Aracosia, and even to the confines of India, the expedition was little more than a display of power. The rich and civilised regions of the west, on the contrary, offered attractions which the politicians of Nineveh were keen to discover. Tiglath-Pileser overthrew the ancient kingdoms of Damascus and Hamath, with its nineteen districts, and after receiving tribute from Menahem (which a false reading in the Old Testament ascribes to a non-existent Pul) in 740, placed his vassal Hoshea on the throne of Samaria in 730 in the room of Pekah. Hamath had been aided by Uzziah of Judah; and, on the overthrow of the Syrian city, Judah had to become the tributary of Assyria. Tiglath-Pileser seems to have met with a usurper's fate, and to have fallen in a struggle with another claimant of the throne, Shalmaneser. The chief event of Shalmaneser's reign (727–722) was the campaign against Samaria. The capture of that city, however, was reserved for his successor, Sargon, in 720, who succeeded in founding a new dynasty. Sargon's reign of seventeen years forms an era in later Assyrian history. At the very commencement of it he met and defeated the forces of Elam, and so prepared the way for the future conquest of that once predominant monarchy. He came into conflict, also, with the kingdoms of Ararat and Van in the north; and the policy of the countries beyond the Zagros was henceforth influenced by the wishes of the Assyrian court. But it was in the west that the power of Nineveh was chiefly felt. Syria and Palestine were reduced to a condition of vassalage, Hamath was depopulated, and Egypt, then governed by Ethiopian princes, first came into collision with Assyria. The battle of Raphia in 719, in which the Egyptians and their Philistine allies were defeated, was an omen of the future; and from this time onward the destinies of civilised Asia were fought out between the two great powers of the ancient world. As the one rose the other fell; and just as the climax of Assyrian glory is marked by the complete subjugation of Egypt, so the revolt of Egypt was the first signal of the decline of Assyria. The struggle between the representative states of the East led, as was natural, to the appearance of the Greek upon the stage of history. Sargon claims the conquest of Cyprus as well as Phœnicia, and his effigy, found at Idalium, remains to this day a witness of the fact. Babylonia, however, was the point of weakness in the empire. It was too like, and yet too unlike, Assyria to be otherwise than a dangerous dependency; and its inhabitants could never forget that they had once been the dominant nation. New blood had been infused into them by the arrival of the Caldai, whose leader, Merodach-Baladan, the son of Yacin, called Mardokempados in Ptolemy's canon, had taken advantage of the troubles which closed the life of Tiglath-Pileser to possess himself of Babylonia; and for twelve years he continued master of the country, until in 710 Sargon drove him from the province, and crowned himself king of Babylon. Merodach-Baladan had foreseen the attack, and endeavoured to meet it by forming alliances with Egypt and the principalities of Palestine. The confederacy, however, was broken up in a single campaign by the Assyrian monarch; Judea was overrun, and Ashdod razed to the ground. Sargon, who now styled himself king of Assyria and Babylon, of Sumir and Accad, like Tiglath-Pileser before him, spent the latter part of his reign in internal reforms and extensive building. A new town, called after his name, was founded to the north of Nineveh (at the modern Kouyunjik), and a magnificent palace was erected there. The library of Calah was restored and enlarged, in imitation of his semi-mythical namesake of Agane, whose astrological works were re-edited, while special attention was given to legislation. In the midst of these labours Sargon was murdered, and his son, Sennacherib, ascended the throne on the 12th of Ab 705 B.C. Sennacherib is a typical representative of the great warriors and builders of the second Assyrian empire, and is familiar to the readers of the Old Testament from his invasion of Judah, which the native monuments assign to the year 701. The check he received at Eltakeh, where he was met by the forces of Egypt and Ethiopia, saved the Jewish king, not, however, before his towns had been ravaged, a heavy tribute laid upon the capital, and his allies in Ascalon and Ekron severely punished. At the commencement of this campaign Sennacherib had reduced Tyre and Sidon, and the overthrow of these centres of commerce caused a transfer of trade to Carchemish. Babylonia had shaken off the yoke of Assyria at the death of Sargon under Merodach-Baladan, who had escaped from his captivity at Nineveh, but was soon reduced to obedience again, and placed under the government of the Assyrian viceroy Belibus. In 700, however, the year after the Judæan war, Babylon rebelled once more under the indomitable Merodach-Baladan, and Suzub, another Chaldean. Sennacherib was occupied with a naval war—the first ever engaged in by the Assyrians—against a body of Chaldeans who had taken refuge in Susiana, and the revolt in his rear was stirred up by the Susianian king. But the insurgents were totally defeated; Assur-nadin-sum, Sennacherib's eldest son, was appointed viceroy of the southern kingdom; and the Assyrian monarch felt himself strong enough to carry the war into the heart of Elam, wasting the country with fire and sword. A last attempt, made by the Susianians and the Chaldeans of Babylonia, to oppose the power of Assyria was shattered in the hardly-contested battle of Khaluli. The interregnum, however, which marks the last eight years of Sennacherib's rule in Ptolemy's canon, shows that Chaldea still continued to give trouble and resist the Assyrian yoke.

Meanwhile Sennacherib had been constructing canals and aqueducts, embanking the Tigris, and building himself a palace at Nineveh on a grander scale than had ever been attempted before. His works were interrupted by his murder, in 681, by his two sons, who, however, soon found themselves confronted by the veteran army of Essar-haddon, their father's younger and favourite son. Essar-haddon had been engaged in Armenia; but in January 680 he defeated them at Khanirabbat, and was proclaimed king. Soon afterwards he established his court at Babylon, where he governed in person during the whole of his reign. After settling the affairs of Chaldea his first campaign was directed against Syria, where Sidon was destroyed and its inhabitants removed to Assyria, an event which exercised a profound influence upon Asiatic trade. The most remarkable expedition of his reign was into the heart of Arabia, to the kingdoms of Huz and Buz, 980 miles distant from Nineveh, 280 miles of the march being through arid desert. The Assyrian army accomplished a feat never since exceeded. In the north, also, it penetrated equally far, subjugating the tribes of the Caucasus, receiving the submission of Teispes the Cimmerian, and taking posses-

sion of the copper-mines on the most remote frontiers of Media. All this part of the country was now in the hands of Aryan settlers, and each small town had its independent chief, like the states of Greece. In fact, on two sides, on both north and west, the Assyrian empire was in contact with an Aryan population, and among the twenty-two kings who sent materials for Essar-haddon's palace at Nineveh were Cyprian princes with Greek names. But the most important work of Essar-haddon's reign was the conquest of Egypt, which left the ancient world under the rule of a single power for some twenty years, and by fusing the nations of Western Asia together, broke down their differences, spread an equalised civilisation, and first struck out the idea of universal empire. In 672 B.C. the land of the Pharaohs was invaded, Tirhakah, the Ethiopian, driven beyond its borders, and the country divided into twenty governments. Vain efforts to shake off the Assyrian supremacy were made from time to time; but just as Babylon had to look to the foreign Caldai for the championship of its independence, so Egypt found its leaders in Ethiopian princes. In 669 Essar-haddon fell ill, and on the 12th day of Iyyar in the following year he associated his son, Assur-bani-pal, with him in the kingdom. On his death at Babylon in 667, Assur-bani-pal was left sole king. One of his first acts was to appoint his brother Savul-sum-yucin (Sammughes) governor of Babylonia.

Assur-bani-pal, the Sardanapalus of the Greeks, was the "grand monarque" of ancient Assyria. The empire on his accession was at the height of its glory and magnitude; the treasures and products of the world flowed into Nineveh, and its name was feared from the frontiers of India to the shores of the Ægean. Constant wars asserted the superiority of the Assyrian troops, though they drained the empire of money and men; and the luxury, which had come in like a flood, was sapping the foundations of the national strength. Assur-bani-pal, in spite of his victories, his buildings, and his patronage of literature, left a diminished inheritance to his son; and the military expeditions, formerly conducted by the king in person, were now entrusted to his generals. His first work was to check the southward advance of the Cimmerians, who were thus driven upon Asia Minor, and to quell a revolt that had broken out in Egypt. Two campaigns were requisite to effect this, and meanwhile Gyges of Lydia had sent tribute to the formidable Assyrian monarch. War had also broken out with Elam, which ended, after a long and hard struggle, with the complete conquest of the country. It was divided into two states, each ruled by Assyrian vassals. But soon after this (in 652) the first blow was struck which eventually led to the downfall of the empire. A general insurrection suddenly took place, headed by Assur-bani-pal's own brother, the viceroy of Babylonia. Elam, Arabia, Egypt, and Palestine made common cause against the oppressor. Egypt alone, however, under the guidance of Psammitichus, and with the help of Gyges, succeeded in recovering her independence; the wandering tribes of Northern Arabia, Kedar, Zobah, Nabathæa, &c., were chastised, and summary vengeance taken on Babylonia and Elam. Babylon and Cuthah were reduced by famine (649), Sammughes was captured and burnt to death, and fire and sword were carried through Elam. After a protracted war, in which Assur-bani-pal was aided by internal dissensions, Shushan was plundered and razed, and the whole of Susiana reduced to a wilderness. This happened in 643.

Assur-bani-pal's buildings were unrivalled for size and grandeur. Assyrian culture reached its culminating point in his reign, and his palaces glittered with the precious metals, and were adorned with the richest sculpture. The library which he formed at Nineveh far surpassed any that had ever existed before; literary works were collected from all sides; the study of the dead language of Accad was encouraged, grammars and dictionaries were compiled, and learned men of all nations were attracted to the court. Patron of the arts as he was, however, Assur-bani-pal's character was stained by cruelty and sensuality. Under his second name of Sin-inadina-pal, he appears as king of Babylon in Ptolemy's list; and the complete amalgamation of Assyria and Babylonia in the later years of his rule is shown by the appearance of a prefect of Babylon among the Assyrian eponyms. He was succeeded in 625 by his son Assur-ebil-ili. His death was the signal for a general revolt. Nabopolassar, the viceroy of Babylonia, made himself independent; and Assyria, shorn of its empire, was left to struggle for bare existence, until, under Saracus its last monarch, Nineveh was taken and burnt by the Babylonians and Medes.

The seat of empire was now transferred to the southern kingdom. Nabopolassar was followed in 604 by his son Nebuchadnezzar, whose long reign of forty-three years made Babylon the mistress of the world. The whole East was overrun by the armies of Chaldea, Egypt was invaded, and the city of the Euphrates left without a rival. Until systematic explorations are carried on in Babylonia, however, our knowledge of the history of Nebuchadnezzar's empire must be confined to the notices of ancient writers, although we possess numerous inscriptions which record the restoration or construction of temples, palaces, and other public buildings during its continuance. One of these bears out the boast of Nebuchadnezzar, mentioned by Berosus, that he had built the wall of Babylon in fifteen days. Evil-Merodach succeeded his father in 561, but he was murdered two years after, and the crown seized by his brother-in-law, Nergal-sharezer, who calls himself son of Bel-suma-iscun, "king of Babylon." Nergal-sharezer reigned four years, and was succeeded by his son, a mere boy, who was put to death after nine months of sovereignty (555 B.C.). The power now passed from the house of Nabopolassar, Nabu-nahid, who was raised to the throne, being of another family. Nebuchadnezzar's empire already began to show signs of decay, and a new enemy threatened it in the person of Cyrus the Persian. The Lydian monarchy, which had extended its sway over Asia Minor and the Greek islands, had some time before come into hostile collision with the Babylonians, but the famous eclipse foretold by Thales had parted the combatants and brought about peace. Crœsus of Lydia and Nabu-nahid of Babylonia now formed an alliance against the common foe, who had subjected Media to his rule, and preparations were made for checking the Persian advance. The rashness of Crœsus, however, in meeting Cyrus before his allies had joined him, brought about his overthrow; Sardis was taken, and the Persian leader occupied the next fourteen years in consolidating his power in the north. This respite was employed by Nabu-nahid in fortifying Babylon, and in constructing those wonderful walls and hydraulic works which Herodotus ascribes to Queen Nitocris. At last, however, the attack was made; and after spending a winter in draining the Gyndes, Cyrus appeared in the neighbourhood of Babylon. Belshazzar, Nabu-nahid's eldest son, as we learn from an inscription, was left in charge of the city, while his father took the field against the invader. But the Jews, who saw in the Persians monotheists and deliverers, formed a considerable element of the population and army; and Nabu-nahid found himself defeated and compelled to take refuge in Borsippa. By diverting the channel of the Euphrates the Persians contrived to march along the dry river-bed, and enter the city through an unguarded gate. Babylon was taken, and Nabu-nahid shortly afterwards submitted to the conqueror, receiving in return pardon and a residence in

Carmania. He probably died before the end of Cyrus's reign; at all events, when Babylon tried to recover its independence during the troubles that followed the death of Cambyses, it was under impostors who claimed to be "Nebuchadnezzar, the son of Nabu-nahid."

Art, Science, and Literature.—Although in art, as in other things, Assyria was but the pupil and imitator of Babylonia, there was yet a marked difference between its development in the two countries, due partly to natural causes. While the Assyrians had stone in abundance, the Babylonians were obliged to import it from a distance. Brick-clay, on the contrary, lay ready at hand, and architecture among them, consequently, took the forms imposed upon it by the use of bricks instead of stone. Where the Assyrians employed sculptured alabaster to ornament their buildings, the Babylonians contented themselves with enamelled bricks and painted plaster. It is a curious proof of the servile dependence of the northern upon the southern kingdom in artistic matters, that the Assyrians continued to make large use of brick up to the downfall of the empire, in spite of the accessibility of stone and the rapid decay of their palaces caused by the employment of the more fragile material. Still, although Assyrian art clung thus unaccountably to the building materials of another country, it did not dispense with its native stone altogether; and speaking broadly, we may say that the architecture of Nineveh is characterised by the use of stone in contradistinction to the brickwork of Babylonia. Sculpture was naturally developed by the one, just as painting was by the other; and the ornamentation which could be lavished on the exterior in Assyria had to be confined to the interior in Chaldea.

Another distinction between the art of the two monarchies arose from the character of their respective populations. Babylonia was essentially a religious country, and its art, therefore, was primarily religious. Nearly all the great edifices, whose ruins still attract the traveller, were temples, and the inscriptions we possess of the Babylonian princes relate almost wholly to the worship of the gods. In Assyria, on the other hand, the temple was but an appendage of the palace, the king among "these Romans of Asia," as Prof. Rawlinson calls them, being the central object of reverence. While the Chaldean temple, with its huge masses of brickwork, rose stage upon stage, each tier smaller than the lower, differently coloured, and surmounted at the top by a chamber which served at once as a shrine and an observatory, the Assyrian palace was erected upon a mound of rubble, with open courts and imposing entrances, though never more than one or two stories high.

Closely connected with this difference in the religious feelings of the two nations was the greater care and attention paid to burial in Babylonia. As yet not a single tomb has been found in Assyria, while sepulchral remains abound in Chaldea. The vast necropolis of Erech astonishes us by the number of its graves, and the potters of Babylonia were largely employed in making clay coffins. The character of Assyrian art being thus secular, and that of Babylonia sacred and sepulchral, necessarily led to a different application and development of it in the two countries.

We must regard Assyrian art as parallel with later Babylonian, both having branched off from Accadian. In Assyrian we may trace two or even three periods of development; but our want of materials makes it impossible to do this in the case of later Babylonian. Among neither people, however, did art altogether escape from the swathing-bands of its nursery, although it was never crystallised as in ancient Egypt. The oldest monuments of Accad already display it in all its forms, rude and rudimentary though they may be. The terraced temples of Ur, Erech, and other places, mount back to the earliest times of Chaldean history, and we find them already adorned with enamelled bricks, which were first coloured, then glazed, and finally baked in the fire. Terra-cotta cones of various hues, imbedded in plaster, were used for external ornamentation, and at Warka (Erech) coloured half-columns are employed for the same purpose,—an ornamentation which recurs in Sargon's palace at Khorsabad, and was the germ of the many kinds of pillars met with in Assyria. The internal walls of the shrine were bright with paint and bronze and gilding; but the brilliant colouring of the Chaldeans was not reproduced in the northern monarchy where more sombre tints were preferred. The huge structures themselves, of burnt and unburnt brick, were supported by buttresses, and the rain was carried off by elaborately-constructed drains, some of which afford us the earliest examples of the arch. A leaden pipe for the same object was found by Mr Loftus at Mugheir (Ur).

Stone, on account of its scarcity, was highly prized, and used only for sculpture and carving. Fragments of the statue of an Accadian king have been brought from Hammám, and a portrait of Merodach-iddin-akhi, the successful opponent of Tiglath-Pileser I. (1120 B.C.), is cut in low relief on a stone now in the British Museum. Like all other Babylonian stone relics, they are of small size, and of hard black granite, and the royal portrait is interesting not only as being one of the few specimens we possess of Babylonian sculpture, but as showing the marked contrast of the Babylonian face to the typically Jewish features of the Assyrians. If larger stones were rare, however, the same cannot be said of smaller ones, which were used as signets and talismans. These were always incised, and though the figures are frequently rude, and still more often grotesque, they are always clearly cut and vigorous. Indeed, it is clear that emery must have been used for the purpose, while many of the carvings are so minute as to suggest the employment of a magnifying-glass. This, however, seems to be out of the question at so early a date as that to which many of the gems belong, although a crystal lens was discovered by Mr Layard at Nimrúd. The design on the signet-cylinder of the earliest king of Ur of whom we have any knowledge is of a high order of merit.

Next to gem-cutting, pottery was carried to considerable perfection by the Accadians. Some of their vases and lamps exhibit great beauty of form, and bear evidence of the potter's wheel; though the large majority are made by the hand, and extremely rude. Spirited bas-reliefs in terra-cotta, however, have been exhumed at Senkereh, and some small terra-cotta figures may also be assigned to this early period. Metallurgy was more backward. Stone implements were still in use, although weapons and ornaments of bronze and copper are met with in abundance; and even iron was not unknown. Bronze bowls occur in almost every tomb, sometimes wrought with considerable skill. Metallurgic art, however, attained its highest point in the manufacture of gold objects like ear-rings and fillets. The latter may be compared with the gold head-dresses found by Dr Schliemann in the Troad. This backward state of metallurgy is somewhat remarkable when we consider the skill displayed in the making of textile fabrics. The oldest gems portray the most richly embroidered robes, and it is probable that the muslins and carpets for which Babylonia was afterwards so famous were already a branch of industry.

Art in Assyria developed chiefly, as has been said, on the side of architecture and sculpture. Its first period is best represented by the reign of Assur-natsir-pal, in whose palaces we obtain excellent illustrations of its excellences and defects. The period is characterised by a simplicity and vigour which shows itself in the bas-reliefs, where the

figures, more especially the animal forms, are spirited and natural beyond anything that we meet with at a later time. Nothing, for instance, can be bolder and more life-like than the lion-hunt depicted on the slabs of Assur-natsir-pal. There is a freedom in the attitude of the animals which evidences a remarkable grandeur of conception. On the other hand, the execution is somewhat heavy, the perspective is worse even than in later works, and the outlines are reproduced with too servile an exactitude. A background, again, is entirely wanting, the attention of the artist being concentrated upon the principal group. In the second period, which extends from the beginning of the second empire to the reign of Essar-haddon, the freshness and boldness of the preceding stage have passed away. The care once exclusively bestowed upon the chief figures is now shared with an elaborate background, and a pre-Raffaellite minuteness prevails throughout the whole. This, added to a total want of perspective, causes too obtrusive a realism. Still, what is lost in vigour is gained in delicacy and finish, and the general effect of such rich and intricate grouping could not but have been effective. The reign of Assur-bani-pal marks the third and last period of Assyrian art. Drawing has made a rapid advance, and the sculptures furnish several instances of successful foreshortening. The art of this period is distinguished by great softness and chasteness; vegetable forms are represented with admirable skill, and the overcrowding of the preceding stage is avoided by recurring to the plain backgrounds of the first period, or introducing merely the main outlines of a landscape. At the same time, it is clear that Assyrian art is beginning to decline; the freedom and boldness that once marked it tend to disappear, and it is pervaded by a spirit of effeminacy which is well exemplified by the subjects portrayed. For the first time scenes are taken from the harem; the king lies, with his wife seated beside him, banqueting under the shade of the vine; and the lions that Assur-natsir-pal hunted in the open field at the risk of life are now tame creatures, kept in cages, and let out for a royal *battue*, where they have to be whipped into activity.

The effect of this Assyrian bas-relief sculpture was heightened by judicious colouring. Red, blue, black, and white—none of them, however, of very great brilliancy—were laid upon certain parts of the picture, such as the eyes, hair, and fringes of the garments. This partial colouring was also adopted by the Greeks, and it is extremely probable that they borrowed it from Assyria. The beginning of Greek art coincides with the decadence of Assyrian; and the objects found by M. Cesnola and others in Cyprus show us the transition of the one into the other. While the remains found by Dr Schliemann in the Troad do not exhibit any Assyrian influence, the oldest works of art in Greece itself are thoroughly Assyrian in character. Indeed, we can trace the lion-sculpture at Mycenæ through the similar rock-carving at Kumbet, in Phrygia, back to the artists of Nineveh. The lions themselves are Assyrian in all their details, and the pillar against which they rest reappears in the monuments of Assur-bani-pal. Columnar architecture, in fact, obtained a more extensive development in the empire of the Tigris than has ever been the case elsewhere. The half columns of ancient Chaldea germinated into a wonderful variety of elaborate forms. The most peculiar are those which rest with circular pedestals upon the backs of lions, dogs, and winged bulls. The chasteness of Hellenic taste preserved it from this Eastern fantasticness, but the Doric and Ionic pillars had their first home on the banks of the Tigris. There was something in the round firm column which was congenial to the mind of the Assyrian.

Indeed, it may be said that solidity and realism underlie all Assyrian art. Muscular strength and power of an intensely earthly and human nature is expressed in their bas-reliefs and the colossal bulls that guarded the palace from the entrance of evil spirits. Nowhere else in the world can we find such an embodiment of brute force and unimaginative energy. Not only is Assyrian art valuable as disclosing the genesis of Hellenic, but yet more so as filling up a vacant chapter in the history of æsthetics. The divine calm and mysterious immensity of Egyptian sculpture was not more foreign to the Greek than the stiff unspirituality and coarse vigour of the Assyrians, which found in the lion an appropriate symbol. But the Assyrian artists did not confine themselves to architecture and bas-reliefs. Gem-cutting was carried to high perfection, and even sitting statues of "the great king" were attempted. These, however, were not so successful as the terra-cotta models, some of which are of great beauty. Indeed, the potters' work of Nineveh can quite vie with that of ancient Greece, and their lamps seem to be prototypes of those which we find in the tombs of Athens or Syracuse. Besides porcelain, glass was also manufactured, and though transparent glass does not appear to have been known before the reign of Sargon, coloured glass, with all the tints that we admire in Venetian ware, had long been an article of trade. Metallurgy, again, was a branch of industry in which the Assyrians particularly excelled. Their gold ear-rings and bracelets are admirable both in design and workmanship; their bronze casts are free from the narrowness of their sculptures in stone; and so well were they acquainted with the art of inlaying one metal with another, that our modern artists have been content to learn from them the method of covering iron with bronze. Household furniture, too, gives us a high idea of Assyrian skill. Like gem-cutting, it brought out the Chinese minuteness and accuracy of the people, and the profuse, though tasteful ornamentation of the seats is especially to be noticed.

It is unfortunate that our knowledge of the development of art in the sister kingdom is still so imperfect. As has been said, however, it is characterised by painting rather than sculpture, and the use of brick instead of stone. The few bas-reliefs that exist are small and inferior in execution; but brilliant colouring and a lavish use of the metals made up for this want. The walls were covered with the most costly materials, and "images portrayed with vermilion" excited the admiration of the stranger. The love of bright colours, in contrast with the sober hues of the Assyrian palaces, led also to the cultivation of gardens, and the hanging gardens of Babylon, raised upon tiers of arches, were one of the wonders of the world. The Babylonian had, too, a strong sense of humour. In the engraved gems and metal-work of the southern empire, we miss the finish and minute care of the sister-kingdom, but they are replaced by a spirit of grotesqueness and serio-comedy. In pottery and the manufacture of textile fabrics the Babylonians particularly excelled; their carpets and variegated dresses were highly prized, while their fondness for music was much celebrated. The history of the latter art, however, both in Babylonia and in Assyria, has yet to be traced.

The science of Assyria, like most things else, was derived from Accad. A large number of its technical terms were borrowed from the Turanian, and continued to the last an enduring monument of the debt owed by the Semite to his predecessor. At the same time, he did not remain a mere imitator; science received a development in his hands which might have been looked for in vain from a Turanian race. First and foremost comes the astronomy, for which Babylonia was so famous in the ancient world. Its beginning goes back to the time when the Accadai had not yet descended from their mountain fastnesses. The zenith was

fixed above Elam, and not above Babylonia, and "the mountain of the East," the primitive home of the race, was supposed to support the firmament. The shrines on the topmost terraces of the temples were used also as observatories. Ur had its royal observatory, and so probably had the other cities of Chaldea; in Assyria they existed at Assur, Nineveh, and Arbela, and the astronomers-royal had to send in their reports to the king twice a month. At an early date the stars were numbered and named; but the most important astronomical work of the Accadians was the formation of a calendar. This came after the division of the heavens into degrees, since the twelve months (of 30 days each) were named after the zodiacal signs, and would seem to belong to about 2200 B.C. Somewhat strangely, the Accadian calendar appears to have passed to the Assyrians (and through them to the Jews) through the medium of the Aramæans. The year being roughly made to consist of 360 days, intercalary months had to be added, one of them being regularly inserted every six years, and two others being counted in by the priests when necessary. The *soss* of 60 years, the *ner* of 600, and the *sar* of 3600, were merely cycles dependent upon the general mathematical system of the Babylonians, which made 60 the unit, and then multiplied it by the factors of itself. The week of 7 days was in use from an early period; indeed, the names which we still give to the days can be traced to ancient Babylonia; and the seventh day was one of *sulum* or "rest." The night was divided into three watches; but this was afterwards superseded by the more accurate division of the day into 12 *casbu* (of 2 hours each), corresponding to the divisions of the equator, each *casbu* being further subdivided into 60 minutes, and these again into 60 seconds. The sections of the equator contained 30 degrees each—a degree being 60 sosses or minutes; but since an astrolabe, now in the Museum, divides each of the 12 sections in the outer circle into 20 degrees, and those in the inner circle into 10 degrees, it is plain that a different system was adopted for astrological purposes. Eclipses were carefully recorded from a very remote epoch, and since some of these are said to have happened "according to calculation," and others "contrary to calculation," their recurrence after a cycle of eighteen years must have been roughly determined. One of the Assyrian reports states that a watch was kept for an eclipse of the sun on the three last days of the month, but that, contrary to expectation, the eclipse did not take place, and we possess notices of eclipses which have been verified by modern astronomers, though antecedent to the era of Nabonassar, with whom, so far as Ptolemy knew, the first record of them began. The chief work on astronomy was one compiled for the library of Sargon of Agane in seventy tablets or books, which went through many editions, one of the latest being now in the British Museum. It was called "the illumination of Bel," and was translated into Greek by Berosus. The catalogue of its contents includes observations on comets, on the polestar, the conjunction of the sun and moon, and the motions of Venus and Mars. The main purpose, however, of all these Babylonian astronomical observations was an astrological one; to cast a horoscope, or predict the weather, was the chief business of the Chaldean astronomer. Indeed, the patient minuteness of the meteorological observations is most curious, and it was believed that the same weather recurred after a definite number of years. In the later Assyrian period the study became more scientific, and the observatory reports have something of the precision of modern times. But from a much earlier era we obtain interesting tables of lunar longitudes and numerical equivalents of the daily increase and decrease of the moon. As is implied by the attention given to astronomy, mathematics was fairly advanced. The unit was 60, a very convenient number, especially when used as the denominator of a fraction. A tablet found at Senkereh gives a table of squares and cubes, correctly calculated, from 1 to 60; and a people who were acquainted with the sun-dial, the clepsydra, the lever, and the pulley, must have had no mean knowledge of mechanics. The lens, too, discovered at Nineveh, explains the minuteness of the cuneiform writing on so many of the tablets, and suggests the possibility of artificial aids to the observation of the heavens.

Assyria possessed but little native literature. It was essentially a land of soldiers, and the more peaceful pursuits had their home in Babylonia, where the universities of Erech and Borsippa were renowned down to classical times. It was not until the reign of Assur-bani-pal that any attempt was made to rival Babylon in learning; then for the first time original compositions came from the pens of Assyrian scholars, and works were even written in the dead language of Accad. Syllabaries, together with grammars, dictionaries, and reading-books of Assyrian and Accadian, were drawn up, besides lists of Semitic synonyms. In these grammars and vocabularies lay the germ of comparative philology, and they are otherwise valuable as affording us the earliest native analysis of Semitic speech. But before this closing period of the empire, the Assyrians had been chiefly content to translate the ancient Accadian literature, or re-edit the contents of Babylonian libraries; and the cramping influence of a dead language, in which all the precedents of law and the first principles of science were locked up, could not but make itself felt. Every great city of Chaldea had at least one library, and it was in imitation of this that the royal libraries at Calah, Nineveh, Assur, and elsewhere, were founded. The larger part of the literature was in clay, stamped in minute characters upon baked bricks, *lateruculæ coctiles* as Pliny calls them; but papyrus was also used, though none of this fragile material has been preserved to our day. In fact, the use of papyrus seems to have preceded that of clay, which was not employed until after the settlement of the Accadians in the plains. The clay tablets or books were arranged in order; and we learn from the catalogue of Sargon's library at Agane (about 2000 B.C.) that each was numbered, so that the student had only to write down the number of the tablet he wanted and the librarian thereupon handed it to him. The subjects of Accadian literary composition were multifarious. Among the most interesting are the hymns to the gods, some of which strikingly resemble the Hebrew psalms in substance as well as in form. Indeed, the parallelism of Hebrew and Assyrian poetry seems to have been borrowed from the Accadians. But the similarity of expression and feeling is no less remarkable. Thus we read in one—(1.) "May god, my creator: take mine hands. (2.) Guide thou the breath of my mouth: guide thou mine hands. (3.) O lord of light!" and in another—(1.) "In heaven who is high? Thou alone, thou art high. (2.) In earth who is high? Thou alone, thou art high. (3.) As for thee, thy word in heaven is declared: the gods bow their faces to the ground. (4.) As for thee, thy word in earth is declared: the spirits of earth kiss the ground;" or in a third—(1.) "O Lord, my transgressions are many: great are my sins. (2.) The Lord in the anger of His heart: has confounded me. (3.) God in the strength of His heart: set himself against me." A collection was afterwards made of these hymns, which was used for ritualistic purposes, and regarded as an inspired volume, and has been aptly compared by M. Lenormant with the Rig-Veda of the Hindus. Of an older date is the collection of magic formulæ and charms, chiefly intended to counteract the effects of sorcery and demoniac possession, which go back to the Shamanistic period of Accadian religion. Later than the hymns, but still prior to the second millennium B.C. and

the formation of the calendar, are the mythological poems which grew out of the development of a solar worship and the personification of the attributes of the gods. Two of these poems we possess intact,—on the Deluge and the descent of Istar into Hades,—and part of a third which describes the war of the seven evil spirits against the moon. The first two form the sixth and eleventh books of a very remarkable epic which centred round the adventures of a solar hero, older and originally independent lays being woven into it as episodes. The epic was divided into twelve books, each book dealing with a legend appropriate to the name of the corresponding zodiacal sign. This astronomical basis of the national epic shows how thoroughly the study had penetrated the mind of the people; and the clearness with which we can trace the growth and formation of the whole work throws great light on the history of epic literature generally, and adds one more confirmation to the theory of Wolf. The Assyrians also had their epic, in imitation of the Accadians, and M. Lenormant has pointed out that the Semiramis and Nannarus of the Greeks and the other personages of Ctesias were really figures of this mythical epopee. The historical and chronological works that have been preserved are of purely Assyrian origin, though there is every reason to suppose that when the libraries of Accad come to be excavated similar compositions will be found in them. The legal literature of the Accadians was certainly very extensive, and a collection of fables, one a dialogue between the ox and the horse, and another between the eagle and the sun, has been met with.

Language, Law, and Trade.—As above stated, the language of the primitive Sumirian and Accadian population of Assyria and Babylonia belonged to the Turanian or Ural-Altaic family of speech. The Semitic tribes, who first possessed themselves of the tetrapolis of Sumir or Shinar, and then gradually spread over the whole of Assyria and Babylonia, borrowed many words from their more civilised predecessors, and lent them a few others in return. The so-called Assyrian language is sub-divided into the two dialects of Assyria and Babylonia, the latter dialect being characterised by a preference for the softer sounds, and a fuller use of the vowels. Literature and the influence of a dead language stereotyped it to such an extent that it underwent comparatively little change during the 1500 years during which we can watch its career; at least this is the case with the literary dialect. The closest affinities are with Hebrew and Phœnician; it shares their peculiarities in phonology, grammar, and vocabulary; and some obscure points in Hebrew etymology have already been cleared up by its help. Next to Hebrew, it shows perhaps the greatest resemblance to Arabic; differing most widely, on the other hand, from Aramaic. Aramaic, however, from becoming the *lingua franca* of trade and diplomacy after the fall of Tyre and Sidon, ended in superseding its sister idioms; but in Babylonia this did not happen until after the Persian conquest. See SEMITIC LANGUAGES.

A large number of the legal precedents of an Assyrian judge, like the titles upon which he had to decide, went back to the Accadian epoch. A table of early Accadian laws shows us that the mother occupied the same prominent place as among modern Turanian tribes. The son is punished with a fine for denying his father, but with banishment for denying his mother. On the other hand, the husband can divorce the wife upon payment of a pecuniary compensation, while the wife who repudiates her husband is condemned to be drowned. The life and person of the slave are already under the protection of the state, the master who misuses him being subject to a fine, while the slave could purchase his freedom. The rights of property, however, were strictly guarded by the law; the maximum of interest seems also to have been defined; and houses, land, or slaves could be taken as security for a debt. The carefulness with which deeds were signed and attested, and adjudicated cases reported, the deeds and cases being afterwards enclosed in an envelope of clay on which the names and main points were inscribed, testifies to a widespread study of law. Witnesses and contracting parties generally affixed their seals; but where they were too poor to possess any, a nail-mark was considered sufficient. In the Accadian period a father could assign property to his son during his lifetime, though he could not put him in possession; and in later times a limited power of willing was in existence. The private will of Sennacherib, in which he bequeaths certain treasures to his favourite son Essar-haddon, is one of the most curious documents of antiquity; unlike other persons, the monarch does not require any witnesses. Great activity of trade is evidenced by this development of law. But here again we must note a distinction due to situation between the northern and southern kingdoms. Of the Chaldeans, it is emphatically said that "their cry was in their ships," and we have many indications of early commerce with the southern coast of Arabia. The trade of Assyria, on the other hand, was wholly overland; and its first fleet was the one built by Phœnician captives for Sennacherib, when pursuing the fugitive Chaldeans through the Persian Gulf. Like the Jews, however, the Assyrians showed an aptitude for trade from the very first. The earliest Semitic settlements in Babylonia seem to have been mainly for commercial purposes, and their career there may be compared with that of the English in India. In the 12th century B.C. the trading spirit had so thoroughly pervaded them that not only were objects of utility and art a marketable commodity, but we find Tiglath-Pileser I. bringing trees from the countries he had overrun, and acclimatising them in Assyria. The fullest development of business and commerce, however, does not show itself until the 8th and 7th centuries B.C., when Nineveh was a busy centre of trade. Sidon and Tyre had been ruined by the Assyrian kings—indeed, it is very possible that the obstinate wars with the Phœnician cities had their origin in commercial jealousy, and trade had accordingly transferred itself to Carchemish, which was conveniently situated on the Euphrates. The maneh of Carchemish became the standard of weight, and Aramaic the common language of trade. The interest upon money was usually at 4 per cent.; but sometimes, more especially when objects like iron were borrowed, at 3 per cent. Payment might still be made in kind; but more ordinarily in bars of the three chief metals, which were weighed, though mention of coined money also occurs. Houses could be let on lease, and the deeds which conveyed them give a careful inventory of the property and its appurtenances. Commercial relations extended from India on the one side, whence came ivory and the teak found at Mugheir, which Sennacherib probably means by "wood of Sinda," to the tin islands of Cornwall on the other.

Religion and Mythology.—The earliest religion of Accad was a Shamanism resembling that of the Siberian or Samoyed tribes of to-day. Every object had its spirit, good or bad; and the power of controlling these spirits was in the hands of priests and sorcerers. The world swarmed with them, especially with the demons, and there was scarcely an action which did not risk demoniac possession. Diseases were regarded as caused in this way, and the cherubs, bulls, and other composite creatures which guarded the entrance to a house, were believed to protect it from mischief. In course of time certain spirits (or rather deified powers of nature) were elevated above the rest into the position of gods: and at the head of all stood the

Triad of Na or Anna, "the sky," Ea, "the earth," and Mulge, "the lord of the underworld." The old Shamanism gradually became transformed into a religion with a host of subordinate semi-divine beings; but so strong a hold had it upon the mind, that the new gods were still addressed by their spirits. The religion now entered upon a new phase; the various epithets applied to the same deity were crystallised into fresh divinities, and the sun-god under a multitude of forms became the central object of worship. This inevitably led to a mythology, the numerous personified attributes passing into demi-gods and heroes. A large part of the Accadian mythology was solar, and the transparency of its proper names which, as in other agglutinative languages, never disguise their primitive meaning, makes it valuable in verifying the so-called "solar theory" of comparative mythology. At this stage of development, however, an important change passed over the old faith. The Semitic settlers in Sumir had adopted the Accadian pantheon and belief, and after a conflict between the discordant religious conceptions of the two races, a great sacerdotal "reform" took place analogous to that of Brahmanism, and the official religion fused them into one whole. The magicians were taken into the priestly body, and the hierarchy of divine beings was determined. The old triad of Na, Ea, and Mulge became the trinity of Anu, Ea, and Bel the Demiurge, all children of Zicu or Zicara, "the sky" (the Sige of Nicolaus Damascenus); Ea, "the god of life and knowledge," "the lord of the abyss," "the king of rivers and the garden," the husband of Bahu (the Bohu of Gen. i. 2), whose spirit pervades the universe, being made the father of Bel-Merodach, the tutelary divinity of Babylon. In accordance with the genius of the sex-denoting Semitic idioms, each deity was furnished with a female principle, and "The god" in Babylonia, and the personified city of Assur, with his wife Seruá, in Assyria, were placed at the head of the Pantheon. Below these four supreme divinities came a second trinity of the Moon-god, Sun-god, and Air-god, and the seven together formed "the seven magnificent deities." After these were arranged "the fifty great gods," and then the 300 spirits of heaven, and the 600 spirits of earth, among whom was found a place for the primeval divinities of Accad as well as for the many local deities of Chaldea. The most dreaded of "the spirits of earth" were "the seven spirits" who were born "without father and mother" in the encircling abyss of ocean, and carried plague and evil over the earth. An old myth told of their war against the moon, which was deputed to watch over the interests of mankind.

Along with the establishment of the Babylonian official religion, an astro-theology was created by the introduction of astronomy into the religious sphere. The "spirits" of the various stars were identified with the gods of the new creed, Merodach, for instance, properly one of the forms of the sun-god, being identified with the planet Jupiter, and the five planetary deities were added to the seven magnificent gods, making up altogether "the twelve chiefs of the gods." The elaboration of this astro-theology was also accompanied by the formation of a cosmogony. The details of the latter are to be found in the fragments of Berosus and Nicolaus Damascenus, whose statements are confirmed by the inscriptions, and they show a remarkable resemblance to the cosmogonies of Genesis and Phœnicia. It must be remembered that both Phœnicians and Hebrews profess to have migrated from Chaldea.

The resemblance is still more striking when we examine the Babylonian mythology. The sacred tree of Babylonia, with its guardian "cherubs"—a word, by the way, which seems of Accadian origin—as well as the flaming sword or thunderbolt of fifty points and seven heads, recall Biblical analogies, while the Noachian deluge differs but slightly from the Chaldean one. Indeed, the Jehovistic version of the flood story in Genesis agrees not only in details, but even in phraseology with that which forms the eleventh lay of the great Babylonian epic. The hero of the latter is Tam-zi or Tammuz, "the sun of life," the son of Ubara-tutu, "the glow of sunset," and denotes the revivifying luminary of day, who sails upon his "ark" behind the clouds of winter to reappear when the rainy season is past. He is called Sisuthrus by Berosus, that is, Susru "the founder," a synonym of Na "the sky." The mountain on which his ark rested was placed, as already noticed, in Nisir, south-west of Lake Urumiyeh. Its peak, whereon the first altar was built after the deluge, was the legendary model after which the *zigurats* or towers of the Babylonian temples were erected. Besides the account of the flood, fragments have been met with of stories resembling those of the tower of Babel or Babylon, of the creation, of the fall, and of the sacrifice of Isaac,—the latter, by the way, forming probably the first lay of the great epic. The sixth lay we possess in full. It describes the descent of Istar into Hades in pursuit of her dead husband Dū-zi, "the offspring," the Babylonian Adonis. Dū-zi is but another form of Tam-zi, and denotes the sun when obscured by night and winter. At each of the seven gates of Hades the goddess left some portion of her apparel, until she at last reached the abode of the dead, dark and joyless, where dust alone is the food of the unhappy shades. In the midst rose the golden throne of the spirits of earth, beneath which welled "the waters of life," and here, too, was the seat of Bahu. Bahu, as queen of the underworld, smote Istar with many diseases, and confined her in Hades until her brother the Sun-god complained to the Moon-god and Ea, who sent a sphinx to pour the waters of life upon the imprisoned goddess and restore her to the light of day. This myth gives a good idea of the Chaldean conception of the next world. Certain favoured individuals, however, might look forward to a happier state of existence. A psalm which invokes blessings upon the king wishes him everlasting life in "the land of the silver sky," where the gods feast and know no evil. It will be observed that the Babylonian Hades (like the Hebrew Sheol) is not very dissimilar to the Homeric one; and the possibility of borrowing on the part of the Greeks is suggested by the fact, that the seven-headed serpent of Hindu legend is of foreign origin, being taken from the seven-headed serpent of the Accadians, "which lashes the waves of the sea," while the story of Andromeda came through Phœnician hands from a Chaldean myth which forms the subject of one of the lays of the great epic. So, too, the Occanus of Homer finds its prototype in the encircling abysmal waters of Accadian geography, and the *fravashis* and *mithras* of Mazdaism were introduced by the Magian (or Turanian) population found in Media by the Aryan invaders.

But the old Shamanistic ideas survived also in Assyria and Babylonia, and so were handed on to the Jews. An elaborate system of augury flourished down to the last days of the empire, and omens were drawn from every event that could possibly happen. Magic formulæ for warding off the attacks of demons were extensively used, and the bronze bowls found by Mr Layard, as well as the part played by charms and demons in the Talmud, show how strongly the belief had seized upon the Jewish mind. Through the Jews and the various Gnostic systems of early Christianity, the primitive doctrines of Accad found their way into the mediæval church, and the features of the mediæval devil may be traced in an Assyrian bas-relief, where a demon with horns, claws, tail, and wings, is being pursued by the god Adar. Even the phylacteries of the Jews go back to the same origin. Accadian magic ordered the sorcerer to bind the charm, twice knotted with seven

knots, round the limbs of the sick man, and this, with the further application of holy water, would, it was believed, infallibly produce a cure, while the same result might be brought about by fixing "a sentence out of a good book on the sufferer's head as he lay in bed." Similar superstitions may yet be detected in the corners of our own land, and still more on the Continent, where the break with the traditions of the past has been less strongly felt. They form an important element in the history of the human intelligence, and the light thrown upon their origin and early fortunes by the revelations of cuneiform discovery has opened a new chapter in the science of religion.

H. S.)

BACCARAT, a town of France, in the department of Meurthe and arrondissement of Lunéville. It has a large export trade of timber, planks, wheelwright's work, and charcoal, and is celebrated for the products of its glassworks, which were established in 1765. Population, 4763.

BACCHIGLIONE, a river of north-eastern Italy, which, rising in the mountains eastward of Trent, passes by Vicenza and Padua, and, after a course of 90 miles, falls into the lagune of Venice, south of Chioggia. It is navigable for large boats as far as Vicenza, and is connected with the Adige by means of a canal. The river is probably the ancient *Togisonus*.

BACCHUS, the Latin name of Dionysus, the god of wine. See DIONYSUS.

BACCHYLIDES, Βακχυλίδης, a famous Greek lyric poet, born at Iulis in Ceos, was the nephew of Simonides, and flourished about 470 years before Christ. He resided long at the court of Hiero of Syracuse with Simonides and Pindar, of whom he is said to have been the rival. His works consisted of odes, dithyrambs, and hymns. Two epigrams contained in the Greek *Anthology* ascribe to him peculiar softness and sweetness of style. The few remains of his writings are contained in the collections of Brunck, Bergk, Bland, and Hartung. They have been published separately by Neue, *Bacchylidis Cei Frag.*, Berl., 1823.

BACCIO DELLA PORTA, called FRA BARTOLOMMEO DI S. MARCO, a celebrated historical and portrait painter, was born at Savignano, near Florence, in 1469, and died in 1517. He received the first elements of his artistic education from Cosimo Roselli; and after leaving him, devoted himself to the study of the great works of Leonardo da Vinci. Of his early productions, which are distinguished for their grace and beauty, the most important is the fresco of the Last Judgment, in which he was assisted by his friend, Mariotto Albertinelli. While he was engaged upon some pieces for the convent of the Dominican friars, he made the acquaintance of Savonarola, who quickly acquired great influence over him; and Baccio was so affected by his cruel death, that he soon after entered the convent, and for some years gave up his art. He had not long resumed it, in obedience to his superior, when the celebrated Raffaelle came to Florence and formed a close friendship with him. Bartolommeo learned from the younger artist the rules of perspective, in which he was so skilled, while Raffaelle owes to the *frate* the improvement in his colouring and handling of drapery, which was noticeable in the works he produced after their meeting. Some years afterwards he visited Rome, and was struck with admiration and a feeling of his own inferiority when he contemplated the masterpieces of Michel Angelo and Raffaelle. With the latter, however, he remained on the most friendly terms, and when he departed from Rome, left in his hands two unfinished pictures which Raffaelle completed. Bartolommeo's figures had generally been small and draped. These qualities were alleged against him as defects, and to prove that his style was not the result of want of power, he painted the magnificent figure of St Mark, and the undraped figure of St Sebastian. The latter was so well designed, so naturally and beautifully coloured, and so strongly expressive of suffering and agony, that it was found necessary to remove it from the place where it had been exhibited in the chapel of a convent. The majority of Bartolommeo's compositions are altar-pieces, and few of them are to be met with out of Tuscany. They are remarkable for skill in the massing of light and shade, richness and delicacy of colouring, and for the admirable style in which the drapery of the figures is handled, Bartolommeo having been the first to introduce and use the lay-figure with joints.

BACH, JOHANN-SEBASTIAN, was born at Eisenach in Thuringia, on March 21, 1685, the same year which gave birth to his great contemporary Handel. His father held a musical appointment from the town council, being himself descended from a musician. The family of the Bachs, like those of some of the great Italian painters, may be cited as one of the most striking instances of hereditary artistic genius. Through four consecutive generations they followed the same calling, counting among their number no less than fifty musicians of more or less remarkable gifts. Even of the first ancestor of the family known to us, a miller and baker, who, owing to religious persecutions, had to leave Pressburg in Austria for the Protestant north of Germany, we are told that in his leisure hours he was fond of playing the lute, the sounds of which, as the old family chronicle naïvely adds, must have mixed sweetly with the clattering of the wheels of his mill. The accumulated artistic gifts and traditions of his forefathers were at last brought to their highest development by the genius of our master, who again transmitted them to his numerous sons. Johann-Sebastian's parents died before he had reached his tenth year, and he was left to the care of his elder brother, an organist at Ohrdruf, from whom he received his rudimentary musical education. According to a tradition the elder Bach was by no means pleased with the rapid progress of his more gifted brother, and even refused him access to the sources of knowledge available at that primitive period; he was particularly anxious to withhold from him a certain collection of compositions for the pianoforte, by contemporary masters, which, however, the younger Bach contrived to obtain surreptitiously, and which he copied at night in the course of six months. By practising the music thus become his own on the pianoforte, he made himself master of the *technique* of an instrument, the capabilities of which he was destined to enlarge and develop by the works of his own genius. In 1698 his brother died, and Bach, at the age of fourteen, saw himself thrown on his own resources for his further means of support. He went to Lüneburg, where his beautiful soprano voice obtained him an appointment as chorister at the school of St Michael. In this manner he became practically acquainted with the principal works of vocal music, continuing at the same time his practice on the organ and pianoforte. A special teacher of any of these instruments, or, indeed, of the theory of music, Bach seems never to have had, at least

not to our knowledge, and his style shows little affinity to the modes of expression in use before him. In some measure, indeed, it may be said that he new-created his own style, and, at the same time, that of modern music in general, a proof both of the originality of his power and of the autodidactic kind of his training. Nevertheless, Bach was anxious to profit by the examples of contemporary masters of his art. We hear of frequent trips to the neighbouring cities of Hamburg, Lübeck, and Celle, at that time important centres of artistic life. In the first-mentioned city Keiser created sensation by the unrivalled splendour of his operatic productions, while at Lübeck the celebrated organist, Buxtehude, excited the enthusiastic admiration of the young art-aspirant. In Celle, on the other hand, a celebrated band, composed chiefly of French artists, offered an opportunity for the practical study of orchestral music. Such were the elements of his self-education, to which must be added his thorough knowledge of Palestrina and other masters of the grand old Italian school, of most of whose works Bach possessed copies written with his own hand.

At the age of eighteen Bach returned to Thuringia, where his executive skill on the organ and pianoforte attracted universal attention, and even obtained him various musical appointments, of which we mention as the most important that of court organist to the duke of Weimar. One, and not the least welcome, of his official duties was the composition of sacred music. One of his most beautiful sacred cantatas, *Ich hatte viel Bekümmerniss*, was composed during his stay at Weimar. An amusing incident of his otherwise quiet and eventless career also belongs to this time. We are speaking of his musical combat with the celebrated French organist, J. Louis Marchand, who had reached Dresden on his travels, and lorded it over his artistic colleagues at the Saxon court in the most sublime manner. The injured musicians, in their endeavours to humble the pride of the Frenchman, at last hit upon the idea of proposing a competition on the organ between him and Bach, whose fame at that time had begun to spread far beyond his place of residence. He was summoned to Dresden, and the day of the tournament fixed, at which the court and all the musical celebrities of the town were to be present. At first Marchand treated his young and comparatively unknown rival with scorn, but on hearing him perform at a preparatory meeting, he was so struck with Bach's power that he ignominiously quitted the field, and vanished from Dresden before the day of the contest arrived. This triumph led to Bach's appointment as musical conductor (*Kapellmeister*) to the duke of Köthen, which he held from 1717-1723, after a previous stay at Weimar for nearly nine years. In 1723 he removed to Leipsic, where the position of cantor at the celebrated "Thomasschule," combined with that of organist at the two principal churches of Leipsic, was offered to him. It was here that the greater part of his works were composed, mostly for the immediate requirements of the moment. Several of them he engraved himself, with the assistance of his favourite son, Friedemann. The further course of his life ran smoothly, only occasionally ruffled by his altercations with his employers, the town-councillors of Leipsic, who, it is said, were shocked by the "unclerical" style of Bach's compositions, and by his independent bearing generally. He was married twice, and had by his two wives a family of eleven sons and nine daughters. In 1747 Bach made a journey to Potsdam by the invitation of Frederick the Great, who, himself a musical amateur, received the master with distinguished marks of regard. He had to play on the numerous pianofortes of the king, and also to try the organs of the churches of Potsdam. Two years after this event his sight began to fail, and before long he became perfectly blind, a circumstance which again coincides with the fate of his great contemporary, Handel. Bach died of apoplexy on the 28th July 1750. His loss was deplored as that of one of the greatest organists and pianoforte players of his time. Particularly his powers of improvisation are described as unrivalled by any of his contemporaries. Of his compositions comparatively little was known. His MS. works were at his death divided amongst his sons, and many of them have been lost in the course of time; only about one-half of his greater works were recovered, when, after the lapse of nearly a century, the verdict of his neglectful contemporaries was reversed by an admiring posterity.

The history of this Bach revival is closely connected with the name of Mendelssohn, who was amongst the first to proclaim by word and deed the powers of a genius almost too gigantic to be grasped by the receptivity of one generation. By the enthusiastic endeavours of Mendelssohn, Schumann, and others, the circle of Bach's worshippers has increased rapidly. In 1850, a century after his death, a society was started for the correct publication of all of Bach's remaining works, to which music owes the rescue from oblivion of some of its sublimest emanations. Amongst those who have vastly contributed to establish the *rapport* between our master's genius and modern lovers of art, we also mention Dr Robert Franz, himself one of Germany's greatest lyrical composers, who has edited and adapted to the resources of the modern orchestra several of Bach's most beautiful works. Of these works, comprising almost all the different forms of music, vocal and instrumental, barring the opera, we can enumerate only the most important ones, referring the reader for further information to the biographical and critical works by Bach's son, Philipp Emmanuel, by Forkel, and more recently by Bitter and Spitta. The last-mentioned book has appeared quite lately, and exceeds its predecessors both by comprehensiveness of research and critical appreciation. Of his numerous and sacred oratorios, cantatas, and similar choral works, we name the so-called Christmas oratorio (1734), the Passion music to the words of St John, and that infinitely grander to the gospel of St Matthew (1734), also his Mass in B minor, one of the greatest masterpieces of all times, and the Magnificat in D. Another cantata is constructed on Luther's grand chorale, *Ein' feste Burg*. The most celebrated amongst his pianoforte compositions is the so-called *Woltemperirte Clavier*, a collection of preludes and fugues in the different keys of the scale. For the orchestra we name the *Grande Suite in D*, and for his favourite instrument, the organ, the so-called *Chromatic Fantasia*. It remains to add a few words about Bach's position in the history of musical development. By Marx, a well-known critical writer, he has been called the "Founder and Father of German Music;" and it cannot be denied that no other German composer before him had attained a specifically national type of musical utterance as distinguished from that of other nations. This applies both to matter and manner. Bach has frequently founded his grandest conceptions on the simplest tune of old chorales, that is, of purely popular effusions of pious fervour, such as had survived in the living memory of the nation from the time of Luther and his great revival of religious feeling. Sometimes these tunes were adapted for religious purposes from still older songs of a secular character, being thus thoroughly interwoven with the inmost feeling of the German people. In raising these simple creations of popular growth to the higher sphere of art, Bach has established his claim to the name of the creator of the *Germanic* as opposed to the *Romance* phase of musical art. This spirit of German, or to speak more

accurately, North German nationality, thoughtful yet *naïve*, earnest yet tender, has also reacted on the form of Bach's creations. Bach's counterpoint, compared with the polyphonous splendour of Palestrina or Orlando di Lasso, is, as it were, of a more intense, more immediately personal kind. In his sacred cantatas, the alternate exclamations of the voices sometimes rise to an almost passionate fervour of devotion, such as is known only to the more individualised conception of human relations to the Deity peculiar to Protestant worship,—applying that term in a purely emotional, that is, entirely unsectarian sense. It is thus that Bach has vivified the rigid forms of the fugue with the fire of individual passion. About the peculiarities of his style, from a technical point of view, we can speak no further. How his style and his genius, neglected by his contemporaries, and obscured by other masters, like Haydn and Mozart, starting from a different basis and imbued with a different spirit, have ultimately been destined to exercise a potent spell on modern art, we have indicated already. (F. H.)

BACH, KARL PHILIPP EMMANUEL, second son of the above, was born at Weimar on the 14th March 1714, and died at Hamburg on the 14th September 1788. He was perhaps the most highly gifted musician of the eleven brothers, and his influence on the development of certain musical forms gives him a prominent place in the history of the art. He studied at the Thomasschule and afterwards at the university of Leipsic, devoting himself, like several of his brothers, to jurisprudence. In 1738 he took up his residence in Berlin, where he was soon afterwards appointed chamber musician to Frederick the Great. In 1767 he was allowed, after considerable negotiation, to relinquish his situation at court in order to accept the post of kapellmeister at Hamburg, where he passed the last twenty-one years of his life. He was a very prolific composer, his most ambitious work being the oratorio of *The Israelites in the Wilderness*. The majority of his compositions, however, were naturally written for his instrument, the clavier. His *Versuch über die wahre Art das Klavier zu spielen* (Essay on the true method of harpsichord playing) was long a standard work, and Clementi professed to have derived from Bach his distinctive style of pianoforte playing. Haydn is said to have acknowledged in his old age his deep obligation to the works of Philipp Emmanuel Bach. From them he certainly learned the form of the sonata and symphony, of which Bach may fairly claim to have been the originator, though Haydn enriched it and gave it permanence. This fact gives Bach's name a distinction to which the intrinsic merits of his compositions might not entitle him, it being now generally agreed by the best critics that he was a somewhat feeble imitator of his father's style.

BACHE, ALEXANDER DALLAS, a distinguished American physicist, who has gained a wide reputation as superintendent of the great American Coast Survey, was a great-grandson of Benjamin Franklin, and was born at Philadelphia, 19th July 1806. In 1821 he entered the military academy at West Point, and graduated there with the highest honours in 1825. For some time he acted as assistant professor in the academy, holding at the same time a commission as lieutenant of engineers, in which capacity he was engaged for a year or two in the erection of coast fortifications. He occupied the post of professor of mathematics in the university of Pennsylvania from 1827 to 1836, and was then made president of the newly-instituted Girard College. In this capacity he undertook a journey through some of the principal countries of Europe, in order to examine their systems of education, and on his return published a very valuable report. In 1843, on the death of Professor Hassler, he was appointed by Government to the office of superintendent of the coast survey. He succeeded in impressing Congress with a sense of the great value of this work, and by means of the liberal aid it granted, he carried out a singularly comprehensive plan with great ability and most satisfactory results. By a skilful division of labour, and by the erection of numerous observing stations, the mapping out of the whole coast proceeded simultaneously under the eye of the general director. Nor were the observations confined to mere description of the coast-line; the several stations were well supplied with instruments, and a vast mass of magnetic and meteorological observations was collected, such as must infallibly prove of infinite service in the future progress of physical science. The annual reports issued by the superintendent were admirable specimens of such summaries, and secured for him a high reputation among European savants. Professor Bache contributed numerous papers to scientific journals and transactions, and laboured earnestly to raise the position of physical science in America. For some months before his death, which took place at Newport, 17th February 1867, he was afflicted with softening of the brain, caused, perhaps, by intense and long-continued mental exertion.

BACHELOR, a word of various meaning, and of exceedingly obscure origin. In modern times the most common significations of it are—(1), an unmarried person; (2), one who has taken the lowest degree in any of the faculties at a university. At various times, however, it has signified either a young man in general, from which the first of the modern meanings was easily developed; or a knight who was unable to lead a body of retainers into the field, *i.e.*, to use the technical phrase, was not able *lever bannière*; or, finally, an ecclesiastic at the lowest stage of his course of training. It has also been pointed out that *bacheleria*, which meant the body of aspirants to knighthood, came to be used as synonymous with *gentry*.

Etymology gives little help in arranging these meanings so as to discover the unity underlying them. In mediæval Latin the word *baccalaria* (connected by Ducange with *vasseleria*, by Stubbs with *bacca*, *i.e.*, *vacca*, a cow), which, according to Diez, is peculiar to the south of France and the north of Spain, signified a certain portion of land, the size and tenure of which imposed on the possessor certain feudal duties. The possessor was called *baccalarius*, and the name readily acquired the signification of one who, from poverty or other cause, as youth, was not able to take rank as a knight. As a third stage in the use of the word, Diez marks out the application of it to denote the lowest degree in a university. But though these transitions from the primitive meaning may perhaps appear natural, there is no historic evidence of their having taken place. The same applies to the five meanings given in Ducange.

We look with more prospect of success to the old French words *bacelle*, *bacelote*, *bachelette*, *bachelerie*, *bachelage*, which have all the meaning of youth, apprenticeship. They may possibly be connected with the Celtic or Welsh words, *bach*, little, *bachgen*, a boy. (See Wedgwood, *s.v.*, who is of opinion that the *baccalarius* of the north of Spain is not in any way connected with our word *bachelor*.) It is very probable that this is truly the root of the word. It has, however, been frequently connected with *baculus*, a stick, from which is supposed to have come *bacularius*, as the word used often to be spelled. (See *Promptorium Parvulorum*, *s.v.*) Whether the relation in this case is that of *shooting forth* or *budding* (*cf.* the Portuguese *bacharel*, a twig of vine, and Barbazan's derivation from *baccalia*), or the more obvious one suggested by the functions of the *bacularius*, who appears to have acted as the monitor or præpostor at schools (see H. T. Riley, *Chronica Monasterii St Albani*), is very doubtful.

Bachelors, or unmarried persons, have in many countries been subjected to penal laws. The best-known examples of such legislation are those of Sparta and Rome. At Sparta, citizens who remained unmarried after a certain age were subjected to a species of ἀτιμία. They were not allowed to witness the gymnastic exercises of the maidens; and during winter they were compelled to march naked round the market-place, singing a song composed against themselves, and expressing the justice of their punishment. The usual respect of the young to the old was not paid to bachelors (Plut., *Lyc.*, 15). At Athens there was no definite legislation on this matter; but certain minor laws are evidently dictated by a spirit akin to the Spartan doctrine (see Schömann, *Gr. Alterth.*, i. 548). At Rome, though there appear traces of some earlier legislation in the matter, the first clearly known law is that called the Lex Julia, passed about 18 B.C. It does not appear to have ever come into full operation; and in 9 A.D. it was incorporated with the Lex Papia et Poppæa, the two laws being frequently cited as one, Lex Julia et Papia Poppæa. This law, while restricting marriages between the several classes of the people, laid heavy penalties on unmarried persons, gave certain privileges to those citizens who had several children, and finally imposed lighter penalties on married persons who were childless. In Britain there has been no direct legislation bearing on bachelors; but, occasionally, taxes have been made to bear more heavily on them than on others. Instances of this are the Act (6 and 7 Will. III.) passed in 1695; the tax on servants, 1785; and the income tax, 1798.

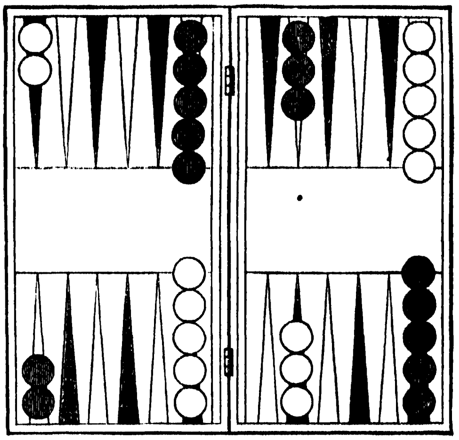
BACHIAN, one of the East Indian islands belonging to the group of the northern Moluccas, situated immediately south of the equator, and lying with its subordinate islands, Mandioli and Kasiruta, between 127° and 127° and 50′E. long. It is of an irregular form, consisting of two distinct mountainous parts, united by a low isthmus, which a slight subsidence would submerge. The area is estimated at about 600 geographical square miles. Sandstone, coralline limestone, and pebbly conglomerate are the prevailing rocks. Of volcanic formations no traces were discovered by Mr Wallace, but other travellers speak of hot springs that seem to point to volcanic activity. The sulphur spring at Taubenkit has a temperature of 125° Fahr.; and a more remarkable example of the same phenomenon exists at Sayowang on the east coast. The highest mountain in the southern half of the island is Gunong Sabella, which is regarded by the natives as the seat of evil spirits. It was partially ascended by Bernstein in 1861. A large portion of the surface is richly wooded, and sago, cocoa-nuts, and cloves are abundantly produced, while, in spite of the extermination of nutmeg-trees by the Dutch, at least one extensive grove remains. Bachian is remarkable as the most eastern point on the globe inhabited by any of the Quadrumana. The interior of the island is uninhabited, and none of the dwellers on the coast are indigenous. They consist of the Sirani or Christian descendants of the Portuguese, of Malays, with a Papuan element, Galela men from the north of Jilolo, and a colony from Tomore, in the eastern peninsula of Celebes. The Sirani preserve various marks of their Portuguese origin, wear a semi-European dress, and celebrate Sunday with dancing and music. The government of the island is vested in a sultan, under the protection of the Dutch, to whom it is becoming of considerable importance from the discovery of coal and other minerals. The chief town or village, called Amassing by the natives, but often spoken of as Bachian, is situated on the isthmus.

BACKGAMMON, a game played with dice, said to have been invented about the 10th century (Strutt). The etymology of the word backgammon is disputed; it is probably Saxon,—Bæc, back; ȝamen, game, *i.e.*, a game in which the players are liable to be sent back. Other derivations are, Dan. *bakke*, tray, *gammen*, game (Wedgwood); and Welsh, *bach*, little, *cammaun*, battle (Henry).

Backgammon is played by two persons, having between them a *backgammon board*. (See diagram.) The board is divided into *tables*, each table being marked with six *points*, coloured alternately white and black. The inner and outer tables are separated from each other by a projecting *bar*.

BLACK.

Black's Home or Inner Table. Black's Outer Table



White's Home or Inner Table. White's Outer Table.

WHITE.

Backgammon Board.

The board is furnished with fifteen white and fifteen black *men*, disposed at the commencement of a game in the manner shown above. The arrangement of the men may be reversed, as it would be if the diagram were turned upside down, and the white men put where the black now stand, and *vice versa*, there being no rule as to whether the play shall be from right to left, or from left to right. It is usual to make the inner table (see diagram) the one nearest to the light (*Académie des jeux; regles du jeu de toute-table*).

Two *dice boxes* are required, one for each player, and a *pair of dice*, which are used by both players. The dice are marked with numbers on each face from one to six, number one being called *ace*; two, *deuce*; three, *trois* (pronounced trey); four, *quatre* (katre); five, *cinque*; and six, *six* (size).

The board being arranged, each player throws one die; the one who throws the higher number has the right of playing first; and he may either adopt the throw originally made by the two players, each throwing one die; or he may throw again, using both dice.

Each player moves his own men from point to point, the moves being determined by throws of the dice made by the players alternately. A player may move any of his men a number of points corresponding to the numbers thrown by him, provided the board is not *blocked* by two or more of his adversary's men occupying the point to which he wishes to move. Thus, suppose white throws cinque, six, he may move one of his men from the left-hand corner of the black's inner table to the left-hand corner of black's outer table for six; he may, again, move the same man five points further on, viz., to the right-hand point of the same table for five, when his move is completed; or he may leave the man first moved six, and move any other man five points, where the board is open. But white cannot move a man for five from the ace point in black's inner table because the six point in that table (*i.e.*, the fifth point from where white moves) is blocked by the black men. Any part of the throw which cannot be moved is of no effect; but it is compulsory for a player to move the whole throw if he can. Thus if the men were differently placed, and white could move a six, and having

done so could not move a five, his move is completed. If, however, by moving the five first, he can afterwards move a six, he may be required to make the move in that manner. All white's moves must be in the direction indicated, viz., from black's inner table to black's outer, and from this to white's outer table, and so on to white's inner table; and all black's moves must be in the contrary direction. Of course, where men are originally placed part of the way home, they only have to traverse the remainder of the distance.

A player in moving must not skip a point which is blocked by his adversary's men. Thus, suppose white's first throw is fives, he cannot move a man from the ace point of black's inner table to the cinque point of black's outer, although that is free; because in moving the first cinque he comes to a point which is occupied by black.

When two similar numbers are thrown (called *doublets*), the player has a double move. Thus, if he throws aces he has to move four aces instead of two, and so on for the other numbers.

When a player moves his men so as to occupy a point with two men, it is called *making a point*. Thus, if ace, trois are thrown and white moves one man from the three in his outer table to the cinque point in his inner table, for trois, and then moves a man from the six point to the cinque point of his inner table, for ace, he makes a point there.

If a player leaves only a single man on a point, or places a single man on an unoccupied point, it is called *leaving a blot*. Thus, if the first throw is six, cinque, and white carries a man from black's inner table as far as he will go, white leaves a blot on the ace point of his opponent's home table.

When a blot is left the man may be taken up, or the blot may be *hit*, if, while it remains, the adversary throws a number which will enable him to place a man on that point. For example, if a blot is left on black's ace point, as in the case previously supposed, and black throws a five, or numbers that make up five, he can hit the blot from his six point; or similarly, if he throws seven, or numbers that make up seven, he can hit the blot from the three men posted in his outer table. The man hit is placed on the bar, and has to *enter* black's inner table again at white's next throw.

It will be observed that black in taking up white leaves a blot himself, which subjects him to be taken up if white enters with an ace. If this should occur, black's man is placed on the bar, and has at his next throw to enter white's inner table, whence he has to start his journey home. Suppose white to have a blot as before on black's ace point, and black to throw sixes, black could then move two men from white's outer table to his own bar point (so called because it is close to the bar), and thence again to his own ace point, when he would hit white without leaving a blot.

The point on which a man is entered must not be blocked by two or more men belonging to the adversary. Thus, to carry on the illustration, if white now throws aces, or sixes, or six, ace, he cannot enter at all. He is not allowed to move any man while he has one to enter; consequently his throw is null and void, and black throws again. It sometimes happens that one player has a man up, and that his adversary occupies all the points on his own home table with two or more men (called having his table *made up*). In this case, the player with a man up cannot enter; and as it is useless for him to throw, his adversary continues throwing until he is obliged to open a point on his inner table.

Two blots may be taken up at once if the adversary throws numbers that will hit them both. It is possible with doublets to take up four blots at once, but this could scarcely happen in a game between players of any proficiency.

The game proceeds by moving the men round towards home, or by hitting blots and sending them back, until one of the players gets all his men into his inner table or home. As soon as this stage is reached, the player who has accomplished it begins to take his men off the board or to *bear* them. Thus, suppose he has several men on every point of his table, and throws six, quatre; he bears one man from his six point, and one from his quatre point. If his six point is unoccupied, he can bear a six from his cinque point, or from the highest point which is occupied, and so on with smaller numbers, provided the numbers thrown are higher than the points occupied; if lower, the throw must be moved. A player has the option of moving a man when he can, instead of bearing it. Thus, in the case originally given the six must be borne, because a six cannot be moved; but the quatre may be moved if preferred, by moving a man from the six point to the deuce point, or from cinque point to the ace point. Doublets entitle to bear or move four men in accordance with the previous rules. The adversary similarly bears his men as soon as he gets them all home. If, after a player has commenced bearing his men, he should be hit on a blot, he must enter on his adversary's inner table, and must bring the man taken up into his own inner table before he can bear any more.

Whoever first bears all his men wins the game:—a single game or *hit* if his adversary has borne any of his men; a double game or *gammon* if the adversary has not borne a man; and a triple game or *backgammon*, if, at the time the winner bears his last man, his adversary, not having borne a man, has one in the winner's inner table.

When a series of games is played, the winner of a hit has the first throw in the succeeding game; but if a gammon is won, the players each throw a single die to determine the first move of the next game.

In order to play backgammon well, it is necessary to know all the chances on two dice, and to apply them in various ways. The number of different throws that can be made is thirty-six. (See Hazard.) By taking all the combinations of these throws which include given numbers, it is easily discovered where blots may be left with the least probability of being hit. For example, to find the chance of being hit where a blot can only be taken up by an ace; the adversary may throw two aces, or ace in combination with any other number up to six, and he may throw each of these in two different ways, so that there are in all eleven ways in which an ace may be thrown. This deducted from thirty-six (the total number of throws), leaves twenty-five; so that it is 25 to 11 against being hit on an ace. It is very important to bear in mind the chance of being hit on any number. The following table gives the odds against being hit on any number within the reach of one or two dice:—

It is	25	to 11,	or about	9	to 4,	against being hit on	1
,,	24	,, 12,	or	2	,, 1,	,,	2
,,	22	,, 14,	or about	3	,, 2,	,,	3
,,	21	,, 15,	or	7	,, 5,	,,	4
,,	21	,, 15,	,,	7	,, 5,	,,	5
,,	19	,, 17,	,,	9½	,, 8½,	,,	6
,,	30	,, 6,	,,	5	,, 1,	,,	7
,,	30	,, 6,	,,	5	,, 1,	,,	8
,,	31	,, 5,	or about	6	,, 1,	,,	9
,,	33	,, 3,	or	11	,, 1,	,,	10
,,	34	,, 2,	,,	17	,, 1,	,,	11
,,	33	,, 3,	,,	11	,, 1,	,,	12

The table shows that if a blot must be left within the reach of one die (*i.e.*, on any number from 1 to 6), the nearer it is left to the adversary's man, the less probability there is of its being hit. Also, that it is long odds against being hit on a blot which is only to be reached with double dice, and that, in that case (on any number from 7 to 11), the further off the blot is, the less chance there is of its being hit.

The table assumes that the board is open for every possible throw. If part of the throw is blocked by an intervening point being held by adverse men, the chance of being hit may be less. Thus, a blot may be hit on an eight with deuces; fours; cinque, trois (twice); or six, deuce (twice). If the fourth point is blocked, the blot cannot be hit with deuces or fours, and consequently the chance of its being hit is reduced from 30 to 6 to 32 to 4, or from 5 to 1 to 8 to 1.

Two principles, then, have to be considered in moving the men:—(1.) To make points where there is the best chance of obstructing the opponent; (2.) When obliged to leave blots, to choose the position in which they are least likely to be hit, *i.e.*, either as near as possible to an adverse man, or as far as possible from any adverse men; or where the intervening points are blocked by the player's own men.

At the beginning of the game it is advisable, if possible, to secure the cinque point in your own inner table, or the cinque point in your adversary's inner table, or both. If you succeed in this, you should then play a bold game in hopes of winning a gammon. The next best point to gain is your own bar point; and the next to that the quatre point in your own inner table.

If you are fortunate enough to secure all these points, and your adversary's inner table is less favourably made up, it is then to your interest to open your bar point (in expectation of compelling your adversary to run out of your inner table with a six), and also to keep any men you may have in the outer tables spread (*i.e.*, not to crowd a number of men on one point). In this case you have a good chance of hitting the man your adversary brings out, and also of hitting the man he has left on your ace point.

If you succeed in taking both these men, and your adversary has a blot in his inner table, it will be to your interest not to make up your own table, but to leave a blot there on purpose, in hopes of his entering on it. You will then have a probability of hitting a third man, which, if accomplished, will give you considerable odds (according to Hoyle, 4 to 1) in favour of winning a gammon; whereas if you have only two of his men up, the odds are against your gammoning him.

The best move for every possible throw at the commencement of a game is as follows:—If you throw aces (the best of all throws), move two on your bar point and two on your cinque point. This throw is often given to inferior players by way of odds.

Ace deuce: move the ace from your adversary's ace point (if playing for a hit only), and the deuce from the five men placed in your adversary's outer table. If playing for a gammon, move the ace from the six to the cinque point in your inner table.

Ace trois: make the cinque point in your inner table.

Ace quatre and ace cinque: move the ace from your adversary's ace point, and the quatre or cinque from the five men in your adversary's outer table. If playing for a gammon, play the ace on the cinque point in your inner table.

Ace six: make your bar point.

Deuces: move two on the quatre point in your inner table, and two on the trois point in your opponent's inner table. If playing for a gammon, move two on the quatre point in your inner table, and two from the five men in your adversary's outer table.

Deuce trois and deuce cinque: move two men from the five placed in your adversary's outer table.

Deuce quatre: make the quatre point in your own table.

Deuce six: move a man from the five in your adversary's outer table, and place him on the cinque point in your own table.

Threes: play two on the cinque point in your inner table, and three on the quatre point of your adversary's inner table. For a gammon, play two on your cinque point and two on your trois point in your inner table.

Trois quatre: move two men from the five in your opponent's outer table.

Trois cinque: make the trois point in your own table.

Trois six: bring a man from your adversary's ace point as far as he will go.

Fours: move two on the cinque point in your adversary's inner table, and two from the five in his outer table. For a gammon, move two men from the five in your opponent's outer table to the cinque point in your own table.

Quatre cinque and quatre six: carry a man from your adversary's ace point as far as he will go.

Fives: move two men from the five in your adversary's outer table to the trois point in your inner table.

Cinque six: move a man from your adversary's ace point as far as he will go.

Sixes (the second best throw): move two on your adversary's bar point, and two on your own bar point.

Subsequent moves depend on the intervening throws; consequently the problem becomes too complicated for analysis. Some general rules, however, may be given.

In carrying the men home carry the most distant man to your adversary's bar point, next to the six point in your outer table, and then to the six point in your inner table. By following this rule as nearly as the throws admit, you will carry the men to your inner table in the fewest number of throws. When all are home but two, it is often advisable to lose a point, if by so doing you put it in the power of a high throw to save a gammon.

If, in endeavouring to gain your own or your adversary's cinque point, you have to leave a blot and are hit, and your adversary is forwarder in the game than you, you must put another man on your cinque or bar point, or into your adversary's table. If this man is not hit, you may then make a point, and so get as good a game as your opponent. If it is hit, you must play a *back* game (*i.e.*, allow him to take up as many men as he likes); and then in entering the men taken up, endeavour to secure your adversary's ace and trois points, or ace and deuce points, and keep three men upon his ace point, so that if you hit him from there you still keep the ace point protected.

To find which is the forwardest, reckon how many points you have to bring all your men home to the six point in your inner table. Add to this six for every man on the six point in your tables, five for every man on your cinque point, and so on; and then make the same calculation for your adversary's men.

Avoid carrying many men upon the trois or deuce point in your own tables, as these men are out of play, and the board is left open for your adversary.

Whenever you have taken up two of your adversary's men, and have two or more points made in your inner table, spread your other men to take the best chance of making another point in your tables, and of hitting the man your adversary enters. As soon as he enters, compare his game with yours, and, if equal or better, take up his man, except when playing for a hit only, and your playing the throw gives you a better chance for the hit.

Always take up a man if the blot you leave in making the move can only be hit with double dice, except when playing for a hit only, and you already have two of your opponent's men in your tables, and your game is forwardest; because your having three of his men in your tables gives him a better chance of hitting you without leaving a blot than if he has only two.

In entering a man which it is to your adversary's advantage to hit, leave the blot upon the lowest point you can, *e.g.*, ace point in preference to deuce point, and so on; because this crowds his game by taking out of it the men played on the low point.

When your adversary is bearing his men, and you have two men in his table, say on his ace point, and several men in the outer table, it is to your advantage to leave one man on the ace point, because it prevents his bearing his men to the greatest advantage, and gives you the chance of his leaving a blot. But if, on calculation, you find that you can probably save the gammon by bringing both your men out of his table, do not wait for a blot. To make this calculation, you must ascertain in how many throws you can bring all your men home (a throw averaging eight points), and in how many throws he can bear all his men, on the assumption that he will bear on the average two men at each throw.

The laws of backgammon (as given by Hoyle) are as follows:—

1. When a man is taken from any point, it must be played; when two men are taken from it, they also must be played. 2. A man is not supposed to be played till it is placed upon a point and quitted. 3. If a player have only fourteen men in play, there is no penalty inflicted, because by his playing with a lesser number than he is entitled to, he plays to a disadvantage for want of the deficient man to make up his tables. 4. If he bear any number of men before he has entered a man taken up, and which of course he was obliged to enter, such men so borne must be entered again in the adversary's tables as well as the man taken up. 5. If he have mistaken his throw and played it, and his adversary have thrown, it is not in the choice of either of the players to alter it, unless they both agree so to do.

Russian Backgammon is played with the same implements as backgammon. The men are not placed on the board, but both black and white are entered in the same table by throws of the dice, and both players move

in the same direction round to the opposite table. A player is not obliged to enter all his men before he moves any; and he can take up blots on entering, although he has some of his men, which have never been entered, off the board. But, while a player has a man up, he must enter it before entering any more, or moving any of those already entered. If he cannot enter the man that is up, he loses the benefit of the throw.

A player who throws doublets must move not only the number thrown, but also doublets of the number corresponding to the opposite side of the dice; thus, if he throws sixes, he must first enter or move the sixes, as the case may be, and then aces, and he also has another throw. If he throws doublets a second time, he moves according to the rule already given, and throws again, and so on. The privilege is sometimes restricted by not allowing this advantage to the first doublets thrown by each player. It is sometimes extended by allowing the thrower of deuce, ace, to choose any doublets he likes on the opposite sides of the dice, and to throw again. The restriction with regard to the first doublets thrown does not apply to deuce, ace, nor does throwing it remove the restriction with regard to first doublets.

A player must first be able to complete the doublets thrown. If the player cannot move the whole throw, he cannot take the corresponding doublets, and he is not allowed another throw if he cannot move all the points to which he is entitled. In other respects the game is similar to ordinary backgammon. The chief object in the game is for the player who has his men in advance to secure as many successive points as possible, so that his adversary may be unable to pass or hit the forward men. (H. J.)

BACKHUYSEN, Ludolf, an eminent painter of the Dutch school, was born at Embden, in Hanover, in 1631, and died in 1709. He was brought up as a merchant at Amsterdam, but early discovered so strong a genius for painting that he relinquished business and devoted himself to art. He studied first under Everdingen and then under Dubbels, two eminent masters of the time, and soon became celebrated for his sea pieces. He was an ardent student of nature, and frequently exposed himself on the sea in an open boat in order to study the effects of tempests. His compositions, which are very numerous, are nearly all variations of one subject, and in a style peculiarly his own, marked by intense realism or faithful imitation of nature. In his later years Backhuysen employed his time in etching and caligraphy. Several of his best pieces are in the gallery of the Louvre.

BACON, FRANCIS

BACON, Francis, Baron Verulam, Viscount St Alban, was born at York House in the Strand, London, on the 22d January 1561. He was the youngest son of Sir Nicholas Bacon, the celebrated lawyer and statesman, who for twenty years of Elizabeth's reign held the seals as lord keeper. His mother, the second wife of Sir Nicholas, was a daughter of Sir Anthony Cooke, formerly tutor to Edward VI. She was a woman of considerable culture, well skilled in the classical studies of the period, and a warm adherent of the Reformed or Puritan Church. One of her sisters was married to the famous Lord Treasurer Burghley. Very little is known of Bacon's early life and education. His health being then, as always, extremely delicate, he probably received much of his instruction at home. Yet, Rawley tells us, "his first and childish years were not without some mark of eminency; at which time he was endued with that pregnancy and towardness of wit, as they were presages of that deep and universal apprehension which was manifest in him afterwards, and caused him to be taken notice of by several persons of worth and place, and especially by the queen, who, as I have been informed, delighted much to confer with him and to prove him with questions; unto whom he delivered himself with that gravity and maturity above his years that her majesty would often term him, *The young lord keeper.*" In April 1573 he was entered at Trinity College, Cambridge, where for three years he resided with his brother Anthony. Our information with regard to these important years is singularly scanty. We know only that Bacon at Cambridge, like Descartes at La Flèche, applied himself diligently to the several sciences as then taught, and came to the conclusion that the methods employed and the results attained were alike worthless and erroneous. Although he preserved a reverence for Aristotle (of whom, however, he seems to have known but little), he learned to despise the Aristotelian philosophy. It yielded no fruit, was serviceable only for disputation, and the end it proposed to itself was a mistaken one. Philosophy must be taught its true business, and to attain its new aim a new method must be devised. With the first germs of this great conception in his mind, Bacon left the university in 1576.

In the same year he and his brother Anthony were entered *de societate magistrorum* at Gray's Inn, and a few months later he was sent abroad with Sir Amyas Paulet, the English ambassador at Paris. He spent some time in that city, and travelled through several of the French provinces. The disturbed state of government and society in France at that time must have afforded him much valuable political instruction; and it has been commonly supposed that certain *Notes on the State of Christendom*, usually printed in his works, contain the results of his observations. But Mr Spedding has shown that there is no reason for ascribing these "Notes" to him, and that they may be attributed with more probability to one of his brother Anthony's correspondents.

The sudden death of his father in February 1579 necessitated Bacon's return to England, and exercised a very serious influence on his fortunes. A considerable sum of money had been laid up by Sir Nicholas in order to purchase an estate for his youngest son, the only one otherwise unprovided for. Owing to his sudden death, this intention was not carried out, and but a fifth part of the money descended to Francis, who thus began his career in comparative poverty. It was one of the gravest misfortunes of his life: he started with insufficient means, acquired a habit of borrowing, and was never afterwards out of debt. As it had become absolutely necessary that he should adopt some profession by which an adequate income would be yielded, he selected that of law, and took up his residence at Gray's Inn in 1579.

Nothing throws so clear a light on the career of any great man as a knowledge of his character and aims when he made the first step into the world. We learn from this how he himself desired to shape his course, and at every point can see how far his actions correspond to the end he had placed before him. We have, fortunately, information from Bacon himself on these points. In the fragment *De Interpretatione Naturæ Proœmium* (written probably about 1603) he analyses his own mental character, and lays before us the objects he had in view when he entered on public life. If his opening sentence, *Ego cum me ad utilitates humanas natum existimarem*, seems at first sight a little arrogant, it must be remembered that it is the arrogance of the μεγαλόψυχος, who thinks himself worthy

of great things, and *is* worthy; it is a great self-esteem, based upon a consciousness of great powers. This grand and comprehensive aim, the production of good to the human race through the discovery of truth, was combined in him with the more practical desire to be of service to his country, service for which he felt himself by birth and education eminently fitted. He purposed, therefore, to obtain, if possible, some honourable post in the state which would give him the means of realising, so far as in him lay, these two great projects, and would at the same time enable him to do somewhat for the church, the third of the objects whose good he had at heart. The constant striving after these three ends is the key to Bacon's life. His qualifications for accomplishing the task he thus set before him were not small. His intellect was far-seeing and acute, quick and yet cautious, meditative, methodical, and free from prejudice. If we add to this account what Bacon himself does not tell us—that he seems to have been of an unusually sweet temper and amiable disposition—we shall have a fairly complete picture of his mental character at the critical period of his entry into the world.

In 1580 he appears to have taken the first step in his projected career by applying, through his uncle, Burghley, for some post at court. His suit, though well received by the queen and the lord treasurer, was unsuccessful; the particulars of it are totally unknown. For two years after this disappointment he worked quietly at Gray's Inn, and in 1582 was admitted an outer barrister. In 1584 he took his seat in Parliament for Melcombe in Dorsetshire, but the notes for the session do not disclose what part he took or what reputation he gained. About the same time he made another application to Burghley, apparently with a view to expediting his progress at the bar. His uncle, who appears to have "taken his zeal for ambition," wrote him a severe letter, taking him to task for arrogance and pride, qualities which Bacon vehemently disclaimed. It is uncertain what success attended this suit; but as his advancement at the bar was unusually rapid, his uncle's influence may not improbably have been exerted in his behalf. Some years later, in 1589, he received the first substantial piece of patronage from his powerful kinsman, the reversion of the clerkship of the Star Chamber being granted to him. The office was valuable, worth about £1600 a year; but it did not become vacant for nearly twenty years, and was thus, as Bacon used to say, "like another man's ground buttailing upon his house, which might mend his prospect, but did not fill his barn." A considerable period of his life had thus slipped away, and his affairs had not prospered. He had written on the condition of parties in the church; he had set down his thoughts on philosophical reform in the lost tract, *Temporis Partus Maximus*; but he had failed in obtaining the position which he looked upon as an indispensable condition of success. A long and eloquent letter to Burghley,[1] written under these circumstances, gives a vivid picture of his mental state, throws additional light upon his character and aims, and at the same time gives a slight hint as to the cause of his uncle's slackness in promoting him.

Some time before this, perhaps as early as 1588, Bacon appears to have become acquainted with Essex, the impetuous and headstrong favourite of Elizabeth's later years. At the close of 1591 he was acting as the earl's confidential adviser, and in the following year Anthony Bacon, returning from the Continent, was also introduced to the young nobleman, and the two brothers exerted themselves diligently in his service. In Feb. 1593 Parliament was called, and Bacon took his seat as member for Middlesex. The special occasion for which the House had been summoned was the discovery of one of the numerous Popish plots that distracted Elizabeth's reign. The conspiracy seemed to be formidable, and Government felt the necessity for increased supplies. As Bacon's conduct in this emergency seriously affected his fortunes, and has been much misunderstood, it is necessary to state, as briefly as possible, the whole facts of the case. The House having been duly informed of the state necessities, assented to a double subsidy, and appointed a committee to draw up the requisite articles. Before this was completed, a message arrived from the House of Lords requesting a conference, which was granted. The committee of the Commons were then informed that the crisis demanded a triple subsidy to be collected in a shorter time than usual, that the Lords could not assent to less than this, and that they desired to confer on the matter. This proposal of the Lords to discuss supply infringed upon the privileges of the Commons; accordingly, when the report of committee was read to the lower House, Bacon stood up and spoke against the proposed conference, pointing out at the same time that a communication from the Lords might be received, but that the actual deliberation on it must be taken by themselves alone. His motion, after some delay, was carried, and the conference was rejected. The Lords upon this lowered their demands, and desired merely to make a communication, which, being legitimate, was at once assented to. The House had then before them the proposal for a triple subsidy, to be collected in three, or, as the motion ultimately was shaped, in four years, instead of in six, as the ordinary custom would have been. Bacon, who approved of the increased subsidy, was opposed to the short period in which it was proposed to be raised. He suggested that it would be difficult or impossible for the people to meet such heavy demands, that discontent and trouble would arise, and that the better method of procedure was to raise money by levy or imposition. His motion appears to have received no support, and the four years' subsidy was passed unanimously. Bacon, as it turned out, had been mistaken in thinking that the country would be unable to meet the increased taxation, and his conduct, though prompted by a pure desire to be of service to the queen, gave deep and well-nigh ineradicable offence. He was accused of seeking popularity, and was for a time excluded from the court. His letter to Burghley,[2] who had told him of the queen's displeasure with his speech, offers no apology for what he had

[1] "I wax now somewhat ancient; one-and-thirty years is a great deal of sand in the hour-glass. . . . I ever bare a mind (in some middle place that I could discharge) to serve her majesty; not as a man born under Sol, that loveth honour; nor under Jupiter, that loveth business (for the contemplative planet carrieth me away wholly); but as a man born under an excellent sovereign, that deserveth the dedication of all men's abilities. . . . Again, the meanness of my estate doth somewhat move me; for though I cannot accuse myself that I am either prodigal or slothful, yet my health is not to spend, nor my course to get. Lastly, I confess that I have as vast contemplative ends as I have moderate civil ends: for I have taken all knowledge to be my province; and if I could purge it of two sorts of rovers, whereof the one with frivolous disputations, confutations, and verbosities, the other with blind experiments and auricular traditions and impostures, hath committed so many spoils, I hope I should bring in industrious observations, grounded conclusions, and profitable inventions and discoveries—the best state of that province. This, whether it be curiosity, or vain-glory, or nature, or (if one take it favourably) *philanthropia*, is so fixed in my mind as it cannot be removed. And I do easily see, that place of any reasonable commandment doth bring commandment of more wits than of a man's own. . . . And if your lordship shall find now, or at any time, that I do seek or affect any place whereunto any that is nearer to your lordship shall be convenient, say then that I am a most dishonest man. And if your lordship will not carry me on, . . . this I will do, I will sell the inheritance that I have, and purchase some lease of quick revenue, or some office of gain that shall be executed by deputy, and so give over all care of service, and become some sorry bookmaker, or a true pioneer in that mine of truth."—(Spedding, *Letters and Life*, i. 108–9.)

[2] Spedding, *Letters and Life*, i. 234–35, *cf.* i. 362. This letter, with those to Puckering or Essex and the queen, i. 240–41, should be compared with what is said of them by Macaulay in his *Essay* on Bacon, and by Campbell, *Lives*, ii. 287.

said, but expresses regret that his motives should have been misunderstood, and that any offence should have been taken. He soon felt that the queen's anger was not to be appeased by such a justification. The attorney-generalship had fallen vacant, and Bacon became a candidate for the office, his most formidable rival being his life-long antagonist, Coke, who was then solicitor. Essex warmly espoused Bacon's cause, and earnestly pressed his claims upon the queen; but his impetuous, pettish pleading tended rather to retard than advance the cause. Burghley, on the other hand, in no way promoted his nephew's interest; he would recommend him for the solicitorship, but not for the attorney-generalship; and it is not improbable that Sir Robert Cecil secretly used his influence against his cousin. The queen delayed the appointment, and Bacon's fortunes, as they then stood, could ill brook delay. He was harassed with debt, and at times so disheartened that he contemplated retirement from public life and devotion to abstract studies. In March 1594 it was at last understood that Coke was to be attorney-general. Essex, though bitterly mortified, at once threw all his energies into the endeavour to procure for Bacon the solicitorship; but in this case also, his method of dealing, which was wholly opposed to Bacon's advice,[1] seemed to irritate, instead of conciliating the queen. The old offence was not yet forgiven, and after a tedious delay, the office was given, in Oct. 1595, to Sergeant Fleming. Burghley and Puckering seem to have assisted Bacon honestly, if not over-warmly, in this second application; but the conduct of Cecil had roused suspicions which were not perhaps without foundation. Essex, to compensate in some degree for Bacon's disappointment, insisted upon presenting him with a piece of land, worth about £1800, and situated probably near Twickenhrm Park. Nor did his kindness cease there; before sailing on the expedition to Cadiz, in the beginning of 1596, he addressed letters to Buckhurst, Fortescue, and Egerton, earnestly requesting them to use their influence towards procuring for Bacon the vacant office of master of the rolls. Before anything came of this application, the Cadiz expedition had resulted in a brilliant success, and Essex became the idol of the army and the people. Bacon saw clearly that such a reputation would assuredly alienate the affections of the queen, who loved not to have a subject too powerful or too popular. He therefore addressed an eloquent and imploring letter to the earl, pointing out the dangers of his position, and urging upon him what he judged to be the only safe course of action, to seek and secure the favour of the queen alone; above all things dissuading him from the appearance of military popularity. His advice, however, was unpalatable and proved ineffectual. The earl still continued his usual course of dealing with the queen, depending solely upon her supposed affection for him, and insanely jealous of any other whom she might seem to favour. His unskilful and unlucky management of the sea expedition to Ferrol and the Azores in no way lowered his popularity with the people, but undoubtedly weakened his influence with the queen.

Bacon's affairs in the meantime had not been prospering. He had increased his reputation by the publication, in 1597, of his *Essays*, along with which were the *Colours of Good and Evil* and the *Meditationes Sacræ*; but his private fortunes were in a bad condition. No public office apparently could be found for him; he failed in the endeavour to retrieve his position by a marriage with the wealthy widow, Lady Hatton, and in 1598 he was arrested for debt. He seems, however, to have been growing in favour with the queen. Some years previously (perhaps about 1594), he had begun to be employed by her in crown affairs, and he gradually acquired the standing of one of the learned counsel, though he held no commission or warrant, and received no salary. At the same time he was no longer on the former friendly terms with Essex, a certain estrangement having sprung up between them, caused no doubt by the earl finding his friend's advice distasteful. The earl's affairs were then at a somewhat critical stage, and as our judgment upon a most important episode in Bacon's life depends upon our knowledge of the events of the ensuing year, it will be requisite to enter more minutely than would otherwise be necessary into proceedings with which Bacon himself had nothing to do.

Ireland was then in a rebellious and discontented condition, and it was somewhat difficult for the English Government to decide either on a definite course of policy with regard to it, or on a leader by whom that policy might be carried out. Upon this subject a violent quarrel took place between the queen and Essex, who for some months retired from court, and refused to be reconciled. At last he came forth from his seclusion, and it was soon understood that he was in person to undertake the subjugation of the rebels in Ireland, with a larger force than had ever before been sent into that country. Into the obscure details of this unhappy campaign it is unnecessary to enter; one fact stands out clearly, that Essex endeavoured to carry out a treasonable design. His jealousy and ill-temper had been so roused that the only course open to him seemed to be the obtaining a powerful military force, the possession of which would compel the queen to reinstate him in her favour. Whether or not this plan was in contemplation before he undertook the Irish expedition is not evident, though even outsiders at that time entertained some suspicions, but there can be no doubt of the treasonable character of the negotiations carried on in Ireland. His plans, probably not very definite, were disturbed by an imperative message from the queen, ordering him not to return to England without her permission. He at once set off, and, trusting apparently to her affection for him, presented himself suddenly before her. He was, for the moment, received kindly, but was soon afterwards ordered to keep his chamber, and was then given into the custody of the lord keeper at York House, where he remained till March 1600. His great popularity, and the general ignorance of the reasons for his imprisonment, stirred up a strong feeling against the queen, who was reported to be influenced by Bacon, and such indignation was raised against the latter, that his friends feared his life would be in danger. The groundless character of this accusation shows how little confidence should be reposed in popular versions of obscure occurrences. It was at last felt necessary that the queen should in some way vindicate her proceedings, and this she at first did, contrary to Bacon's advice, by a declaration from the Star Chamber. This, however, gave little or no satisfaction, and it was found expedient to do what Bacon had always recommended, to have a fair trial, yet not one in which the sentence must needs be damaging to the earl. The trial accordingly took place before a body of her majesty's councillors, and Bacon had a subordinate and unimportant part in the accusation. Essex does not seem to have been at all hurt by his action in this matter, and shortly after his release they were again on friendly terms, Bacon drawing up letters as if to or from the earl with the design of having them brought before the queen. But Bacon did not know the true character of the transactions in which Essex had been engaged. The latter had been released from all custody in August, but in the meantime he had been busily engaged in treasonable correspondence with James of Scotland, and was counting on the Irish army under his ally, Montjoy, the new deputy. But Montjoy had apparently come to see how useless the attempt would be to force upon the queen a settlement of the succession, and declined to go further in the matter

[1] See *Letters and Life*, i. 289, ii. 34.

Essex was thus thrown upon his own resources, and his anger against the queen being roused afresh by the refusal to renew his monopoly of sweet wines, he formed the desperate project of seizing her person and compelling her to dismiss from her council his enemies Raleigh, Cobham, and Cecil. As some pretext, he intended to affirm that his life was in danger from these men, who were in league with the Spaniards. The plot was forced on prematurely by the suspicions excited at court, and the rash attempt to rouse the city of London (8th February 1601) proved a complete *fiasco*. The leaders were arrested that night and thrown into prison. Although the actual rising might have appeared a mere outburst of frantic passion, the private examinations of the most prominent conspirators disclosed to the Government a plot so widely spread, and involving so many of the highest in the land, that it would have been perilous to have pressed home accusations against all who might be implicated. Essex was tried along with the young earl of Southampton, and Bacon, as one of her majesty's counsel, was present on the occasion. Coke, who was principal spokesman, managed the case with great want of skill, incessantly allowing the thread of the evidence to escape, and giving the prisoners opportunity to indulge in irrelevant justifications and protestations which were not ineffectual in distracting attention from the real question at issue. On the first opportunity Bacon rose and briefly pointed out that the earl's plea of having done nothing save what was absolutely necessary to defend his life from the machinations of his enemies was weak and worthless, inasmuch as these enemies were purely imaginary; and he compared his case to that of Pisistratus, who had made use of a somewhat similar stratagem to cloak his real designs upon the city of Athens. He was thereupon interrupted by the earl, who proceeded to defend himself, by declaring that in one of the letters drawn up by Bacon, and purporting to be from the earl to Anthony Bacon, the existence of these rumours, and the dangers to be apprehended from them, had been admitted; and he continued, "If these reasons were then just and true, not counterfeit, how can it be that now my pretences are false and injurious?" To this Bacon replied, that "the letters, if they were there, would not blush to be seen for anything contained in them, and that he had spent more time in vain in studying how to make the earl a good servant to the queen than he had done in anything else." It seems to be forgotten in the general accounts of this matter, not only that Bacon's letters bear out what he said, but that the earl's excuses *were* false. A second time Bacon was compelled to interfere in the course of the trial, and to recall to the minds of those present the real question at issue. He animadverted strongly upon the puerile nature of the defence, and in answer to a remark by Essex, that if he had wished to stir up a rebellion he would have had a larger company with him, pointed out that his dependence was upon the people of London, and compared his attempt to that of the duke of Guise at Paris. To this the earl made little or no reply. Bacon's use of this illustration, and of the former one of Pisistratus, has been much commented on, and in general it seems to have been thought that had it not been for his speeches Essex might have escaped, or, at all events, have been afterwards pardoned. But this view of the matter depends on the supposition that Essex was guilty only of a rash outbreak.[1] That this was not the case was well known to the queen and her council. Unfortunately, prudential motives hindered the publication of the whole evidence; the people, consequently, were still ignorant of the magnitude of the crime, and, till recently, biographers of Bacon have been in a like ignorance.[2] The earl himself, before execution, confessed his guilt and the thorough justice of his sentence, while, with singular lack of magnanimity, he incriminated several against whom accusations had not been brought, among others his sister Lady Rich. After his execution it was thought necessary that some account of the facts should be drawn up and circulated, in order to remove the prejudice against the queen's action in the matter. This was intrusted to Bacon, who drew up a *Declaration of the Practices and Treasons attempted and committed by Robert, late Earl of Essex*, his first draft being extensively altered and corrected by the queen and council. Nothing is known with certainty of the reception given to this official explanation, but the ill feeling against Bacon was not wholly removed, and some years later, in 1604, he published, in the form of a letter to Montjoy, an *Apology* for his action in the case. This *Apology* gives a most fair and temperate history of the relations between Bacon and Essex, shows how the prudent counsel of the one had been rejected by the other, and brings out very clearly what we conceive to be the true explanation of the matter. Everything that Bacon could do was done by him, until the real nature of Essex's design was made apparent, and then, as he had repeatedly told the earl, his devotion and respect were for the queen and state, not for any subject; friendship could never take rank above loyalty. Those who blame Bacon must acquit Essex of all wrong-doing.

Bacon's private fortunes, during the period after the death of Essex, were not in a flourishing condition. He had obtained a grant of £1200 from the fines imposed on Catesby, one of the conspirators, but his debts were sufficient to swallow up this and much more. And, though he was trusted by Elizabeth, and on good terms with her, he seems to have seen that he had no chance of advancement. But her death in 1603, followed by the undisputed succession of James, gave him new hopes; to use his own expression, he found himself "as one awaked out of sleep." It appeared to him that at length the abilities he was conscious of possessing would obtain recognition; he thought that "the canvassing world" had gone, and the "deserving world" had come. He used every means in his power to bring himself under James's notice, writing to all his friends at the Scottish court and to the king himself. He managed to obtain a personal interview with the king, but does not seem to have been much satisfied with it. In fact, while the king confirmed in their situations those who had held crown offices under Elizabeth, Bacon, not holding his post by warrant, was practically omitted. He was, however, continued, by special order of the king, as learned counsel extraordinary, but little or no law business appears to have been intrusted to him. He procured, through his cousin Cecil, the dignity of knighthood, which, contrary to his inclination, he received along with about 300 others, on the 23d July 1603. Between this time and the opening of James's first Parliament he was engaged in literary work, and sent to the king two pamphlets—one on the Union, the other on measures for the pacification of the church. What opinion was formed of them by James is unknown. Shortly after he published his *Apology*; the reception it met with is equally uncertain. In March 1604 Parliament met, and during their short session Bacon's hands seem to have been full of work. It was a busy and stirring time, and events occurred during it which carried within them the seeds of much future dissension. Prerogative and privilege came more than once into collision, the abuses of purveyance and wardship were made matters of conference, though the thorough discussion of them was deferred to a

[1] See Macaulay's *Essay* on Bacon.

[2] The whole story of Essex is given in Mr Spedding's *Letters and Life*. It is also very vigorously told by Mr Bruce in the Introduction to his *Correspondence of James VI. with Sir Robert Cecil*, Camden Society, 1861.

succeeding session; while James's temper was irritated by the objections brought against his favourite scheme of the Union, and by the attitude taken up by the House with regard to religious affairs. The records are barely full enough to enable us to judge very accurately of the share taken by Bacon in these discussions; his name generally appears as the reporter of the committees on special subjects. We can occasionally, however, discern traces of his tact and remarkable prudence; and, on the whole, his attitude, particularly with regard to the Union question, recommended him to James. He was shortly afterwards formally installed as learned counsel, receiving the salary of £40, and at the same time a pension of £60 yearly. He was also appointed one of the commission to treat of the conditions necessary for the Union; and the admirable manner in which the duties of that body were discharged must be attributed mainly to his influence and his complete mastery of the subject. During the recess he published his *Advancement of Learning*, dedicated to the king.

He was now fairly brought into relations with James, and his prospects began to look a little brighter. It is important for us to know what were his ideas upon government, upon parliaments, prerogative, and so forth, since a knowledge of this will clear up much that would seem inexplicable in his life. It seems quite evident[1] that Bacon, from position, early training, and, one might almost think, natural inclination, held as his ideal of government the Elizabethan system. The king was the supreme power, the centre of law and justice, and his prerogative must not be infringed. Parliament was merely a body called to consult with the king on emergencies (*circa ardua regni*) and to grant supplies. King and parliament together make up the state, but the former is first in nature and importance. The duty of a statesman was, therefore, to carry out the royal will in as prudent a manner as possible; he was the servant of the king, and stood or fell according to his pleasure. It is hard to put ourselves at this point of view, and we can with difficulty understand how such a man as Bacon held a theory which seems now so inadequate. But he was not singular in his opinions, and he was undoubtedly sincere; and it is only by keeping them constantly in mind that we can understand his after relations with the king.

In the second Parliament there was not so much scope for the exercise of his powers. The Gunpowder Plot had aroused in the Commons warmer feelings towards the king; they passed severe laws against recusants, and granted a triple subsidy. At the same time they continued the collection of the grievances concerning which they were to move. In the course of this session Bacon married Alice Barnham, "the alderman's daughter, an handsome maiden, to my liking," of whom he had written some years before to his cousin Cecil. Little or nothing is known of their married life.

The third Parliament was chiefly occupied with the commercial and legal questions rising out of the proposed Union, in particular, with the dispute as to the naturalisation of the *Post Nati*. Bacon argued ably in favour of this measure, but the general feeling was against it. The House would only pass a bill abolishing hostile laws between the kingdoms; but the case of the *Post Nati*, being brought before the law courts, was settled as the king wished. Bacon's services were rewarded in June 1607 by the office of solicitor; he had at last gained a step upon the ladder of advancement. His promotion, however, was not rapid; several years passed before he gained another step. Meantime, though circumstances had thrown him too much into active life, he had not forgotten his cherished project of reorganising science. A survey of the ground had been made in the *Advancement*, and some short pieces not published at the time were probably written in the subsequent two or three years. Towards the close of 1607 he sent to his friends a small tract, entitled *Cogitata et Visa*, probably the first draft of what we have under that title. In 1609 he wrote the noble panegyric, *In felicem memoriam Elizabethæ*, and the curiously learned and ingenious work *De Sapientia Veterum*; and completed what seems to have been the *Redargutio Philosophiarum*, or treatise on the idols of the theatre.

In 1610 the famous fourth Parliament of James met. It is not possible to enter minutely into the important occurrences of this short session. Prerogative, despite Bacon's advice and efforts, clashed more than once with liberty; Salisbury's bold schemes for relieving the embarrassment caused by the reckless extravagance of the king proved abortive, and the House was dissolved in February 1611. Bacon took a considerable share in the debates, consistently upheld the prerogative, and seemed yet to possess the confidence of the Commons. The death of Salisbury, occurring soon after, opened a position in which Bacon thought his great political skill and sagacity might be made more immediately available for the king's service. How far he directly offered himself for the post of secretary is uncertain, but we know that his hopes were disappointed, the king himself undertaking the duties of the office. About the same time he made two ineffectual applications for the mastership of the wards; the first, on Salisbury's death, when it was given to Sir George Carey; the second, on the death of Carey. It is somewhat hard to understand why so little favour was shown by the king to one who had proved himself able and willing to do good service, and who, in spite of his disappointments, still continued zealously to offer advice and assistance. At last, in 1613, a fair opportunity for promotion occurred. The death of Sir Thomas Fleming made a vacancy in the chief-justiceship of the King's Bench, and Bacon, after some deliberation, proposed to the king that Coke should be removed from his place in the Court of Common Pleas and transferred to the King's Bench. He gives several reasons for this in his letter to the king, but in all probability his chief motive was that pointed out by Mr Spedding,[2] that in the Court of King's Bench there would be less danger of Coke coming into collision with the king on questions of prerogative, in handling which Bacon was always very circumspect and tender. The vacancy caused by Coke's promotion was then filled up by Hobart, and Bacon, finally, stepped into the place of attorney-general. The fact of this advice being offered and followed in all essentials, illustrates very clearly the close relations between the king and Bacon, who had become a confidential adviser on most occasions of difficulty. That his adherence to the royal party was already noticed and commented on appears from the significant remark of Chamberlain, who, after mentioning the recent changes among the law officials, says, "There is a strong apprehension that little good is to be expected by this change, and that Bacon may prove a dangerous instrument."

Further light is thrown upon Bacon's relations with James, and upon his political sympathies, by the letter to the king advocating the calling of a parliament,[3] and by the two papers of notes on which his letter was founded.[4] These documents, even after due weight is given to all considerations urged in their favour,[5] seem to confirm the view already taken of Bacon's theory of government, and at the same time show that his sympathies with the royal party tended to blind him to the true character of certain courses of action, which can only be justified by a strain-

ing of political ethics. The advice he offered, in all sincerity, was most prudent and sagacious, and *might* have been successfully carried out by a man of Bacon's tact and skill; but it was intensely one-sided, and exhibited a curious want of appreciation of what was even then beginning to be looked on as the true relation of king, parliament, and people. Unfortunately for James, he could neither adopt nor carry out Bacon's policy. The Parliament which met in April 1614 and was dissolved in June, after a stormy session, was by no means in a frame of mind suitable for the king's purposes. The House was enraged at the supposed project (then much misunderstood) of the "Undertakers;" objection was taken to Bacon being elected or serving as a member while holding office as attorney-general; and, though an exception was made in his favour, it was resolved that no attorney-general should in future be eligible for a seat in Parliament. No supply was granted, and the king's necessities were increased instead of diminished. The emergency suggested to some of the bishops the idea of a voluntary contribution, which was eagerly taken up by the noblemen and crown officials. The scheme was afterwards extended so as to take in the whole kingdom, but lost something of its voluntary character, and the means taken to raise the money, which were not what Bacon would have recommended,[1] were calculated to stir up discontent. The general dissatisfaction received a somewhat unguarded and intemperate expression in a letter sent to the justices of Marlborough by a gentleman of the neighbourhood, named St John, in which he denounced the attempt to raise funds in this way as contrary to law, reason, and religion, as constituting in the king personally an act of perjury, involving in the same crime those who contributed, and thereby subjecting all parties to the curses levelled by the church at such offences. St John was summoned before the Star Chamber for slander and treasonable language; and Bacon, *ex officio*, acted as public prosecutor. The sentence pronounced (a fine of £5000 and imprisonment for life) was severe, but it was not actually inflicted, and probably was not intended to be carried out, the success of the prosecution being all that was desired. St John remained a short time in prison, and was then released, after making a full apology and submission. The fine was remitted. It seems incredible that Bacon's conduct on this occasion should have been censured by his biographers. The offence was clear; the law was undoubted; no particular sympathy was excited for the culprit; the sentence was not carried out; and Bacon did only what any one in his place would naturally and necessarily have done. The nature of his office involved him in several trials for treason occurring about the same time, and one of these is of interest sufficient to repay a somewhat longer examination. Edmund Peacham, a clergyman in Somersetshire, had been committed to custody for a libel on his superior, the bishop of Bath and Wells. In searching his house for certain papers, the officers came upon some loose sheets stitched together in the form of a sermon, the contents of which were of such a nature that it was judged right to lay them before the council. As it was at first suspected that the writing of this book had been prompted by some disaffected persons, Peacham was interrogated, and after he had declined to give any information, was subjected to torture. Bacon, as one of the learned counsel, was ordered by council to take part in this examination, which was undoubtedly warranted by precedent, whatever may now be thought of it. Nothing, however, was extracted from Peacham in this way, and it was resolved to proceed against him for treason. Now, in the excited state of popular feeling at that period, the failure of Government to substantiate an accusation of treason would have been a serious matter. The king, with whom the council agreed, seems therefore to have thought it desirable to obtain beforehand the opinions of the four chief judges as to whether the alleged offence amounted to treason. In this there was nothing unusual or illegal, and no objection would at that time have been made to it, but James introduced a certain innovation; he proposed that the opinions of the four judges should be given separately and in private. It may be reasonably inferred that his motive for this was the suspicion, or it may be the knowledge, that Coke did not consider the matter treasonable. At all events when Coke, who as a councillor already knew the facts of the case, was spoken with regarding the new proposal of the king, he at once objected to it, saying that "this particular and auricular taking of opinions" was "new and dangerous," and "not according to the custom of the realm." He at last reluctantly assented, and proposed that Bacon should consult with him, while the other law officers addressed themselves to the three puisne judges. By Bacon's directions, the proposal to the three judges to give their opinions separately was made suddenly and confidently, and any scruples they might have felt were easily overcome. The first step was thus gained, and it was hoped that if "infusion" could be avoided, if the papers bearing on the case were presented to the judges quickly, and before their minds could be swayed by extraneous influence, their decision on the case would be the same as that of the king. It is clear that the extraneous influence to be feared was Coke, who, on being addressed by Bacon, again objected to giving his opinion separately, and even seemed to hope that his brother judges after they had seen the papers would withdraw their assent to giving their decisions privately. Even after the discussion of the case with Bacon, he would not give his opinion until the others had handed in theirs. What the other judges thought is not definitely known, but Bacon appears to have been unable to put in operation the plan he had devised for swaying Coke's judgment,[2] by putting him in some dark manner in doubt that he should be left alone; or if he did attempt this, he was unsuccessful, for Coke finally gave an opinion consistent with what he seems to have held at first, that the book was not treasonable, as it did not disable the king's title. Although the opinions of the judges were not made public, yet as we learn, not only from Bacon, but from a sentence in one of Carleton's letters,[3] a rumour had got about that there was doubt as to the book being treasonable. Under these circumstances, Bacon, who feared that such a report might incite other people to attempt a similar offence, proposed to the king that a second rumour should be circulated in order to destroy the impression caused by the first. "I do think it necessary," he says, "that because we live in an age in which no counsel is kept, and that it is true there is some bruit abroad that the judges of the King's Bench do doubt of the case that it should not be treason, that it be given out constantly, and yet as it were in secret, and so a fame to slide, that the doubt was only upon the publication, in that it was never published. For that (if your majesty marketh it) taketh away or at least qualifieth the danger of the example; for that will be no man's case."[4] Bacon's conduct in this matter has been curiously misrepresented. He has been accused of torturing the prisoner, and of tampering with the judges[5] by consulting them before the trial; nay, he is even represented as selecting this poor clergyman to serve for an example to terrify the disaffected, as breaking into his study and finding there a sermon never intended to be preached, which merely encouraged the people to resist tyranny.[6] All this lavish condemnation is wide of the mark, and rests on a complete misconception of the case. If any blame attaches

to him, it must arise either from his endeavour to force Coke to a favourable decision, in which he was in all probability prompted by a feeling, not uncommon with him, that a matter of state policy was in danger of being sacrificed to some senseless legal quibble or precedent, or from his advice to the king that a rumour should be set afloat which was not strictly true. We do not imagine that in any other politician either of these actions would meet with very severe condemnation.

Bacon's share in another great trial which came on shortly afterwards, the Overbury and Somerset case, is not of such a nature as to render it necessary to enter upon that obscure and thorny subject.[1] It may be noted, however, that his letters about this time show that he had become acquainted with the king's new favourite, the brilliant Sir George Villiers, and that he stood high in the king's good graces. In the early part of 1616, when Ellesmere, the lord chancellor, was dangerously ill, Bacon wrote a long and careful letter to the king, proposing himself for the office, should it fall vacant, and stating as frankly as possible of what value he considered his services would be. In answer, he appears to have received a distinct promise of the reversion of the office; but, as Ellesmere recovered, the matter stood over for a time. He proposed, however, that he should be made a privy councillor, in order to give him more weight in his almost recognised position of adviser to the king, and on the 9th June 1616 he took the oaths and his seat at the council board.

Meanwhile, his great rival Coke, whose constant tendency to limit the prerogative by law and precedent had made him an object of particular dislike to James, had on two points come into open collision with the king's rights. The first case was an action of *præmunire* against the Court of Chancery, evidently instigated by him, but brought at the instance of certain parties whose adversaries had obtained redress in the chancellor's court after the cause had been tried in the Court of King's Bench. With all his learning and ingenuity, Coke failed in inducing or even forcing the jury to bring in a bill against the Court of Chancery, and it seems fairly certain that on the technical point of law involved he was wrong. Although his motive was, in great measure, a feeling of personal dislike towards Ellesmere, yet it is not improbable that he was influenced by the desire to restrict in every possible way the jurisdiction of a court which was the direct exponent of the king's wishes. The other case, that of the *commendams*, was more important in itself and in the circumstances connected with it. The general question involved in a special instance was whether or not the king's prerogative included the right of granting at pleasure livings *in commendam*, *i.e.*, to be enjoyed by one who was not the incumbent. Bacon, as attorney-general, delivered a speech, which has not been reported; but the king was informed that the arguments on the other side had not been limited to the special case, but had directly impugned the general prerogative right of granting livings. It was necessary for James, as a party interested, at once to take measures to see that the decision of the judges should not be given on the general question without due consultation. He accordingly wrote to Bacon, directing him to intimate to the judges his pleasure that they should delay judgment until after discussion of the matter with himself. Bacon communicated first with Coke, who in reply desired that similar notice should be given to the other judges. This was done by Bacon, though he seems to hint that in so doing he was going a little beyond his instructions. The judges took no notice of the intimation, proceeded at once to give judgment, and sent a letter in their united names to the king announcing what they had done, and declaring that it was contrary to law and to their oath for them to pay any attention to a request that their decision should be delayed. The king was indignant at this encroachment, and acting partly on the advice of Bacon, held a council on the 6th June 1616, at which the judges attended. James then entered at great length into the case, censuring the judges for the offensive form of their letter, and for not having delayed judgment upon his demand, which had been made solely because he was himself a party concerned. The judges, at the conclusion of his speech, fell on their knees, and implored pardon for the manner of their letter; but Coke attempted to justify the matter contained in it, saying that the delay required by his majesty was contrary to law. The point of law was argued by Bacon, and decided by the chancellor in favour of the king, who put the question to the judges individually, "Whether, if at any time, in a case depending before the judges, which his majesty conceived to concern him either in power or profit, and thereupon required to consult with them, and that they should stay proceedings in the meantime, they ought not to stay accordingly?" To this all gave assent except Coke, who said that "when the case should be, he would do that should be fit for a judge to do." No notice was taken by the king of this famous, though somewhat evasive, reply, but the judges were again asked what course they would take in the special case now before them. They all declared that they would not decide the matter upon general grounds affecting the prerogative, but upon special circumstances incident to the case; and with this answer they were dismissed. Bacon's conduct throughout the affair has been blamed, but apparently on wrong grounds. As attorney he was merely fulfilling his duty in obeying the command of the king; and in laying down the law on the disputed point, he was, we may be sure, speaking his own convictions. Censure might more reasonably be bestowed on him, because he deliberately advised a course of action than which nothing can be conceived better calculated to strengthen the hands of an absolute monarch.[2] This appeared to Bacon justifiable and right, because the prerogative would be defended and preserved intact. Coke certainly stands out in a better light, not so much for his answer, which was rather indefinite, and the force of which is much weakened by his assent to the second question of the king, but for the general spirit of resistance to encroachment exhibited by him. He was undeniably troublesome to the king, and it is no matter for wonder that James resolved to remove him from a position where he could do so much harm. On the 26th June he was called before the council to answer certain charges, one of which was his conduct in the *præmunire* question. He acknowledged his error on that head, and made little defence. On the 30th he was suspended from council and bench, and ordered to employ his leisure in revising certain obnoxious opinions in his reports. He did not perform the task to the king's satisfaction, and a few months later he was dismissed from office.

Bacon's services to the king's cause had been most important; and as he had, at the same time, acquired great favour with Villiers, his prospects looked brighter than before. According to his custom, he strove earnestly to guide by his advice the conduct of the young favourite. His letters, in which he analyses the various relations in which such a man must stand, and prescribes the course of

[1] The mysterious crimes supposed to be concealed under the obscure details of this case have cast a shadow of vague suspicion on all who were concerned in it. The minute examination of the facts by Mr Spedding (*Letters and Life*. v. 208–347) seems to show that these secret crimes exist nowhere but in the heated imaginations of romantic biographers and historians.

[2] A somewhat similar case is that of the writ *De Rege inconsulto* brought forward by Bacon. See *Letters and Life*, v. 233–36.

action suitable for each, are valuable and deserving of attention.[1] Very striking, in view of future events, are the words [2] in which he gives him counsel as to his dealing with judges: "By no means be you persuaded to interpose yourself by word or letter in any cause depending, or like to be depending, in any court of justice, nor suffer any man to do it where you can hinder it; and by all means dissuade the king himself from it, upon the importunity of any, either for their friends or themselves. If it should prevail, it perverts justice; but if the judge be so just, and of so undaunted a courage (as he ought to be) as not to be inclined thereby, yet it always leaves a taint of suspicions and prejudice behind it." It is probable that Villiers at this time had really a sense of the duties attaching to his position,[3] and was willing to be guided by a man of approved wisdom. It was not long before an opportunity occurred for showing his gratitude and favour. Ellesmere resigned the chancellorship on the 5th March 1617, and on the 7th the great seal was bestowed upon Bacon, with the title of Lord Keeper. Two months later he took his seat with great pomp in the Chancery Court, and delivered a weighty and impressive opening discourse. He entered with great vigour on his new labours, and in less than a month he was able to report to Buckingham that he had cleared off all outstanding Chancery cases. He seemed now to have reached the height of his ambition; he was the first law officer in the kingdom, the accredited minister of his sovereign, and on the best terms with the king and his favourite. His course seemed perfectly prosperous and secure, when a slight storm arising opened his eyes to the frailty of the tenure by which he held his position.

Coke was in disgrace but not in despair; there seemed to be a way whereby he could reconcile himself to Buckingham, through the marriage of his daughter, who had an ample fortune, to Sir John Villiers, brother of the marquis, who was penniless or nearly so. The match was distasteful to Lady Hatton and to her daughter; a violent quarrel was the consequence, and Bacon, who thought the proposed marriage most unsuitable, took Lady Hatton's part. His reasons for disapproval he explained to the king and Buckingham, but found to his surprise that their indignation was strongly roused against him. He received from both bitter letters of reproof; it was rumoured that he would be disgraced, and Buckingham was said to have compared his present conduct to his previous unfaithfulness to Essex. Bacon, who seems to have acted from a simple desire to do the best for Buckingham's own interests, at once changed his course, advanced the match by every means in his power, and by a humble apology appeased the indignation that had been excited against him. It had been a sharp lesson, but things seemed to go on smoothly after it, and Bacon's affairs prospered. In January 1618 he received the higher title Lord Chancellor; in July of the same year he was made Baron Verulam; and in January 1621 he was created Viscount St Alban. His fame, too, had been increased by the publication in 1620 of his most celebrated work, the *Novum Organum*. He seemed at length to have made satisfactory progress towards the realisation of his cherished aims; the method essential for his Instauration was partially completed; and he had attained as high a rank in the state as he had ever contemplated. But history too clearly tells us that his actions in that position were not calculated to promote the good of his country.

Connected with the years during which he held office is one of the weightiest charges against his character. Buckingham, notwithstanding the advice he had received from Bacon himself, was in the habit of addressing letters to him recommending the causes of suitors. In many cases these seem nothing more than letters of courtesy, and, from the general tone, it might fairly be concluded that there was no intention to sway the opinion of the judge illegally, and that Bacon did not understand the letters in that sense. This view is supported by consideration of the few answers to them which are extant.[4] One outstanding case, however, that of Dr Steward,[5] casts some suspicion on all the others. The terms of Buckingham's note [6] concerning it might easily have aroused doubts; and we find that the further course of the action was to all appearances exactly accommodated to Dr Steward, who had been so strongly recommended. It is, of course, dangerous to form an extreme judgment on an isolated and partially understood case, of which also we have no explanation from Bacon himself, but if the interpretation given by Mr Heath be the true one, Bacon certainly suffered his first, and, so far as we can see, just judgment on the case to be set aside, and the whole matter to be reopened in obedience to a request from Buckingham.

It is somewhat hard to understand Bacon's position with regard to the king during these years. He was the first officer of the crown, the most able man in the kingdom, prudent, sagacious, and devoted to the royal party. Yet his advice was followed only when it chimed in with James's own will; his influence was of a merely secondary kind; and his great practical skill was employed simply in carrying out the measures of the king in the best mode possible. We know indeed that he sympathised cordially with the home policy of the Government; he had no objection to such monopolies or patents as seemed advantageous to the country, and for this he is certainly not to be blamed.[7] The opinion was common at the time, and the error was merely ignorance of the true principles of political economy. But we know also that the patents were so numerous as to be oppressive, and we can scarcely avoid inferring that Bacon more readily saw the advantages to the Government than the disadvantages to the people. In November 1620, when a new parliament was summoned to meet on January following, he earnestly pressed that the most obnoxious patents, those of alehouses and inns, and the monopoly of gold and silver thread, should be given up, and wrote to Buckingham, whose brothers were interested, advising him to withdraw them from the impending storm. This prudent advice was unfortunately rejected. But while he went cordially with the king in domestic affairs, he was not quite in harmony with him on questions of foreign policy. Not only was he personally in favour of a war with Spain for the recovery of the Palatinate, but he foresaw in such a course of action the means of drawing together more closely the king and his Parliament. He believed that the royal difficulties would be removed if a policy were adopted with which the people could heartily sympathise, and if the king placed himself at the head of his Parliament and led them on. But his advice was neglected by the vacillating and peace-loving monarch, his proffered proclamation was put

aside, and a weak, featureless production substituted in its place. Nevertheless the new Parliament seemed at first more responsive than might have been looked for. A double subsidy was granted, which was expressly stated to be "not on any consideration or condition for or concerning the Palatinate." The session, however, was not far advanced when the question of patents was brought up; a determined attack was made upon the very ones of which Bacon had been in dread, and it was even proposed to proceed against the referees (Bacon and Montagu) who had certified that there was no objection to them in point of law. This proposal, though pressed by Coke, was allowed to drop; while the king and Buckingham, acting under the advice of Williams, afterwards lord keeper, agreed to give up the monopolies. It was evident, however, that a determined attack was about to be made upon Bacon, and that the proceeding against the referees was really directed against him. It is probable that this charge was dropped because a more powerful weapon had in the meantime been placed in his enemies' hands. This was the accusation of bribery and corrupt dealings in Chancery suits, an accusation apparently wholly unexpected by Bacon, and the possibility of which he seems never to have contemplated until it was actually brought against him. At the beginning of the session a committee had been appointed for inquiring into abuses in the courts of justice. Some illegal practices of certain Chancery officials had been detected and punished by the court itself, and generally there was a disposition to overhaul its affairs, while Coke and Cranfield directly attacked some parts of the chancellor's administration. But on March 14th one Aubrey appeared at the bar of the House, and charged Bacon with having received from him a sum of money while his suit was going on, and with having afterwards decided against him. Bacon's letter[1] on this occasion is worthy of serious attention; he evidently thought the charge was but part of the deliberate scheme to ruin him which had already been in progress. A second accusation (Egerton's case) followed immediately after, and was investigated by the House, who, satisfied that they had just matter for reprehension, appointed the 19th for a conference with the Lords. On that day Bacon, as he had feared, was too ill to attend. He wrote[2] to the Lords excusing his absence, requesting them to appoint a convenient time for his defence and cross-examination of witnesses, and imploring them not to allow their minds to be prejudiced against him, at the same time declaring that he would not "trick up an innocency with cavillations, but plainly and ingenuously declare what he knew or remembered." The charges rapidly accumulated, but Bacon still looked upon them as party moves, and was in hopes of defending himself.[3] Nor did he seem to have lost his courage, if we are to believe the common reports of the day,[4] though certainly they do not appear worthy of very much credit.

The notes[5] bearing upon the interview which he obtained with the king, show that he had begun to see more clearly the nature and extent of the offences with which he was charged, that he now felt it impossible altogether to exculpate himself, and that his hopes were directed towards obtaining some mitigation of his sentence. The long roll of charges made upon the 19th April finally decided him; he gave up all idea of defence, and wrote to the king begging him to show him favour in this emergency.[6] The next day he sent in a general confession to the Lords,[7] trusting that this would be considered satisfactory. The Lords, however, decided that it was not sufficient as a ground for their censure, and demanded a detailed and particular confession. A list of twenty-eight charges was then sent him, to which an answer by letter was required. On the 30th April his "confession and humble submission"[8] was handed in. In it, after going over the several instances, he says, "I do again confess, that on the points charged upon me, although they should be taken as myself have declared them, there is a great deal of corruption and neglect; for which I am heartily and penitently sorry, and submit myself to the judgment, grace, and mercy of the court."[9] On the 3d May, after considerable discussion, the Lords decided upon the sentence, which was,[10] That he should undergo fine and ransom of £40,000; that he should be imprisoned in the tower during the king's pleasure; that he should be for ever incapable of any office, place, or employment in the state or commonwealth; that he should never sit in parliament, or come within the verge of the court. This heavy sentence was only partially executed. The fine was in effect remitted by the king; imprisonment in the tower lasted for about four days; a general pardon (not of course covering the parliamentary censure) was made out, and though delayed at the seal for a time by Lord Keeper Williams, was passed probably in November 1621. The cause of the delay seems to have lain with Buckingham, whose friendship had cooled, and who had taken offence at the fallen chancellor's unwillingness to part with York House. This difference was finally smoothed over, and it was probably through his influence that Bacon received the much-desired permission to come within the verge of the court. He never again sat in parliament.

So ends this painful episode, which has given rise to the most severe condemnation of Bacon, and which still presents great and perhaps insuperable difficulties. On the whole, the tendency of the most recent and thorough researches has been towards the opinion that Bacon's own account of the matter (from which, indeed, our knowledge of it is chiefly drawn) is substantially correct. He distinguishes three ways in which bribes may be given,[11] and ingenuously

[1] *Letters and Life*, vii. 213: "I know I have clean hands and a clean heart, and I hope a clean house for friends or servants. But Job himself, or whosoever was the justest judge, by such hunting for matters against him as hath been used against me, may for a time seem foul, specially in a time when greatness is the mark and accusation is the game."

[2] *Ibid.*, vii. 215–16.

[3] *Ibid.*, vii. 225–26. From the letter to the king (March 25, 1621)—"When I enter into myself, I find not the materials of such a tempest as is comen upon me. I have been (as your majesty knoweth best) never author of any immoderate counsel, but always desired to have things carried *suavibus modis*. I have been no avaricious oppressor of the people. I have been no haughty or intolerable or hateful man in my conversation or carriage. I have inherited no hatred from my father, but am a good patriot born. Whence should this be? For these are the things that use to raise dislikes abroad. . . . And for the briberies and gifts wherewith I am charged, when the book of hearts shall be opened, I hope I shall not be found to have the troubled fountain of a corrupt heart in a depraved habit of taking rewards to pervert justice, howsoever I may be frail, and partake of the abuse of the times."

[4] *Letters and Life*, vii. 227, and Gardiner, *Prince Charles*, &c., i. 450.

[5] *Ibid.*, vii. 236, 238. [6] *Ibid.*, vii. 241.

[7] *Ibid.*, vii. 242–4: "It resteth therefore that, without fig-leaves, I do ingenuously confess and acknowledge, that having understood the particulars of the charge, not formally from the House, but enough to inform my conscience and memory, I find matter sufficient and full, both to move me to desert the defence, and to move your lordships to condemn and censure me."

[8] *Ibid.*, vii. 252–262. [9] *Ibid.*, vii. 261. [10] *Ibid.*, vii. 270.

[11] *Ibid.*, 235–36: "The first, of bargain and contract for reward to pervert justice, *pendente lite*. The second, where the judge conceives the cause to be at an end, by the information of the party or otherwise, and useth not such diligence as he ought to inquire of it. And the third, where the cause is really ended, and it is *sine fraude* without relation to any precedent promise. . . . For the first of them I take myself to be as innocent as any born upon St Innocent's Day, in my heart. For the second, I doubt on some particulars I may be faulty. And for the last, I conceived it to be no fault, but therein I desire to be better informed, that I may be twice penitent, once for the fact and again for the error."

confesses that his own acts amounted to corruption and were worthy of condemnation. Now, corruption strictly interpreted would imply the deliberate sale of justice, and this Bacon explicitly denies, affirming that he never "had bribe or reward in his eye or thought when he pronounced any sentence or order." When we analyse the specific charges against him, with his answers to them, we find many that are really of little weight. The twenty-eighth and last, that of negligence in looking after his servants, though it did him much harm, may fairly be said to imply no moral blame. The majority of the others are instances of gratuities given after the decision, and it is to be regretted that the judgment of the peers gives us no means of determining how such gifts were looked upon, whether or not the acceptance of them was regarded as a "corrupt" practice. In four cases specifically, and in some others by implication, Bacon confesses that he had received bribes from suitors *pendente lite*. Yet he affirms, as we said before, that his intention was never swayed by a bribe; and so far as any of these cases can be traced, his decisions, often given in conjunction with some other official, are to all appearance thoroughly just. In several cases his judgment appears to have been given against the party bestowing the bribe, and in at least one instance, that of Lady Wharton, it seems impossible to doubt that he must have known when accepting the present that his opinion would be adverse to her cause. Although, then, he felt that these practices were really corrupt, and even rejoiced that his own fall would tend to purify the courts from them,[1] he did not feel that he was guilty of perverting justice for the sake of reward. How far, then, is such defence or explanation admissible and satisfactory? It is clear that two things are to be considered: the one the guilt of taking bribes or presents on any consideration, the other the moral guilt depending upon the wilful perversion of justice. The attempt has sometimes been made to defend the whole of Bacon's conduct on the ground that he did nothing that was not done by many of his contemporaries. Bacon himself disclaims a defence of this nature, and we really have no direct evidence which shows to what extent the offering and receiving of such bribes then prevailed. That the practice was common is indeed implied by the terms in which Bacon speaks of it, and it is not improbable that the fact of these gifts being taken by officials was a thing fairly well known, although all were aware of their illegal character, and it was plain that any public exposure of such dealings would be fatal to the individual against whom the charge was made out.[2] Bacon knew all this; he was well aware that the practice was in itself indefensible,[3] and that his conduct was therefore corrupt and deserving of censure. So far, then, as the mere taking of bribes is concerned, he would permit no defence, and his own confession and judgment on his actions contain as severe a condemnation as has ever been passed upon him. Yet in the face of this he does not hesitate to call himself "the justest chancellor that hath been in the five changes since Sir Nicholas Bacon's time";[4] and this on the plea that his intentions had always been pure, and had never been affected by the presents he received. His justification has been set aside by modern critics, not on the ground that the evidence demonstrates its falsity,[5] but because it is inconceivable or unnatural that any man should receive a present from another, and not suffer his judgment to be swayed thereby. It need hardly be said that such an *a priori* conviction is not a sufficient basis on which to found a sweeping condemnation of Bacon's integrity as an administrator of justice. On the other hand, even if it be admitted to be possible and conceivable that a present should be given by a suitor simply as seeking favourable consideration of his cause, and not as desirous of obtaining an unjust decree, and should be accepted by the judge on the same understanding, this would not entitle one absolutely to accept Bacon's statement. Further evidence is necessary in order to give foundation to a definite judgment either way; and it is extremely improbable, nay, almost impossible, that such can ever be produced. In these circumstances, due weight should be given to Bacon's own assertions of his perfect innocence and purity of intention; they ought not to be put out of court unless found in actual contradiction to the facts; and the reverse of this is the case, so far as has yet appeared.[6]

The remainder of his life, though still harassed by want of means, for James was not liberal, was spent in work far more valuable to the world than anything he had accomplished in his high office. In March 1622 he presented to Prince Charles his *History of Henry VII.*; and immediately, with unwearied industry, set to work to complete some portions of his great work. In November 1622 appeared the *Historia Ventorum*; in January 1623, the *Historia Vitæ et Mortis*; and in October of the same year, the *De Augmentis Scientiarum*, a Latin translation, with many additions, of the *Advancement*. Finally, in December 1624, he published his *Apophthegms*, and *Translations of some of the Psalms*; and, in 1625, a third and enlarged edition of the *Essays*.

Busily occupied with these labours, his life now drew rapidly to a close. In March 1626 he came to London, and when driving one day near Highgate, was taken with a desire to discover whether snow would act as an antiseptic. He stopped his carriage, got out at a cottage, purchased a fowl, and with his own hands assisted to stuff it with snow. He was seized with a sudden chill, and became so seriously unwell that he had to be conveyed to Lord Arundel's house, which was near at hand. Here his illness increased, the cold and chill brought on bronchitis and he died, after a few days' suffering, on the 9th April 1626.

Bacon's Works and Philosophy.

A complete survey of Bacon's works and an estimate of his place in literature and philosophy are matters for a volume. It is here proposed merely to classify the works, to indicate their general character, and to enter somewhat more in detail upon what he himself regarded as his great achievement,—the reorganisation of the sciences, and the exposition of a new method by which the human mind might proceed with security and certainty towards the true end of all human thought and action.

---

[1] *Letters and Life*, vii. 242.

[2] *Ibid.*, vii. 244: "Neither will your lordships forget that there are *vitia temporis* as well as *vitia hominis*, and that the beginning of reformations hath the contrary power to the pool of Bethesda, for that had strength to cure only him that was first cast in, and this hath commonly strength to hurt him only that is first cast in."

[3] See, among many other passages, *Essays*, "Of Great Place:" "For corruptions do not only bind thine own hands or thy servant's hands from taking, but bind the hands of suitors also from offering; for integrity used doth the one; but integrity professed, and with a manifest detestation of bribery, doth the other · and avoid not only the fault but the suspicion."

[4] *Cf. Letters and Life*, vii. 560: "I was the justest judge that was in England these fifty years; but it was the justest censure in Parliament that was these two hundred years."

[5] Or on the ground that there was a distinct rule forbidding chancellors and the like officials to take presents. This does not seem to have been the case, if we may judge from what Bacon says, *Letters and Life*, vii. 238.

[6] Not only do the cases, so far as they are known, support Bacon's plea of innocence, but it is remarkable that no attempt at a reversal of any of his numerous decrees appears to have been successful. Had his decrees been wilful perversions of justice, it is scarcely conceivable that some of them should not have been overturned. See *Letters and Life*, vii. 555–562.

Putting aside the letters and occasional writings, we may conveniently distribute the other works into three classes, *Professional, Literary, Philosophical.* Of the Professional works, which include the *Reading on the Statute of Uses,* the *Maxims of Law,* and the treatise (possibly spurious) on the *Use of the Law,* only experts can speak with confidence; and their opinion, so far as it has yet been given, coincides to some extent with Bacon's own estimate of his powers as a lawyer. "I am in good hope," he says, "that when Sir Edward Coke's reports and my rules and decisions shall come to posterity, there will be (whatsoever is now thought) question who was the greater lawyer." If Coke's reports show completer mastery of technical details, greater knowledge of precedent, and more of the dogged grasp of the letter than do Bacon's legal writings, there can be no dispute that the latter exhibit an infinitely more comprehensive intelligence of the abstract principles of jurisprudence, with a richness and ethical fulness that more than compensate for their lack of dry legal detail. Bacon seems indeed to have been a lawyer of the first order, with a keen scientific insight into the bearings of isolated facts, and a power of generalisation which admirably fitted him for the self-imposed task, unfortunately never completed, of digesting or codifying the chaotic mass of the English law.

Among the literary works are included all that he himself designated moral and historical pieces, and to these may be added some theological and minor writings, such as the *Apophthegms.* Of the moral works the most valuable are the *Essays.* It is impossible to praise too highly writings which have been so widely read and universally admired. The matter is of the familiar, practical kind, that "comes home to men's bosoms." The thoughts are weighty, and even when not original, have acquired a peculiar and unique tone or cast by passing through the crucible of Bacon's mind. A sentence from the *Essays* can rarely be mistaken for the production of any other writer. The short, pithy sayings,

> "Jewels, five words long,
> That on the stretched forefinger of all time
> Sparkle for ever,"

have become popular mottoes and household words. The style is quaint, original, abounding in allusions and witticisms, and rich, even to gorgeousness, with piled-up analogies and metaphors.[1] The first edition contained only ten essays, but the number was increased in 1612 to thirty-eight, and in 1625 to fifty-eight. The short tract, *Colours of Good and Evil,* which with the *Meditationes Sacræ* originally accompanied the *Essays,* was afterwards incorporated with the *De Augmentis.* Along with these works may be classed the curiously learned piece, *De Sapientia Veterum,* in which he works out a favourite idea, that the mythological fables of the Greeks were allegorical and concealed the deepest truths of their philosophy. As a scientific explanation of the myths the theory is of no value, but it affords fine scope for the exercise of Bacon's unrivalled power of detecting analogies in things apparently most dissimilar. The *Apophthegms,* though hardly deserving Macaulay's praise of being the best collection of jests in the world, contain a number of those significant anecdotes which Bacon used with such effect in his other writings. Of the historical works, besides a few fragments of the projected history of Britain, there remains the *History of Henry VII.,* a valuable work, giving a clear and animated narrative of the reign, and characterising Henry with great skill. The style is in harmony with the matter, vigorous and flowing, but naturally with less of the quaintness and richness suitable to more thoughtful and original writings. The series of the literary works is completed by the minor treatises on theological or ecclesiastical questions. Some of the latter, included among the occasional works, are admirably sagacious and prudent, and deserve careful study. Of the former, the principal specimens are the *Meditationes Sacræ* and the *Confession of Faith.* The *Paradoxes* (Characters of a believing Christian in paradoxes, and seeming contradictions), which was often and justly suspected, has been conclusively proved by Mr Grosart not to be the work of Bacon.

Philosophical Works.—The great mass of Bacon's writings consists of treatises or fragments, which either formed integral parts of his grand comprehensive scheme, or were closely connected with it. More exactly they may be classified, as is done by the most recent editors, under three heads:—A. Writings which actually formed part of the *Instauratio Magna;* B. Writings originally intended to form parts of the *Instauratio,* but which were afterwards superseded or thrown aside; C. Works connected with the *Instauratio,* but not directly included in its plan.

To begin with the second of these classes, we have under it some important tracts, which certainly contain little, if anything, that is not afterwards taken up and expanded in the more elaborate works, but which are not undeserving of attention, from the difference in the point of view and method of treatment. The most valuable of them are—(1.) The *Advancement of Learning,* of which no detailed account need be given, as it is completely worked up into the *De Augmentis,* and takes its place as the first part of the *Instauratio.* (2.) *Valerius Terminus,* a very remarkable piece, composed probably about 1603, though perhaps retouched at a later period. It contains a brief and somewhat obscure outline of the first two parts in the *Instauratio,* and is of importance as affording us some insight into the gradual development of the system in Bacon's own mind. (3.) *Temporis Partus Masculus,* another curious fragment, remarkable not only from its contents, but from its style, which is arrogant and offensive, in this respect unlike any other writing of Bacon's. The adjective *masculus* points to the power of bringing forth fruit possessed by the new philosophy, and perhaps indicates that all previous births of time were to be looked upon as feminine or imperfect; it is used in a somewhat similar sense in *Letters and Life,* vi. 183, "*In verbis masculis,* no flourishing or painted words, but such words as are fit to go before deeds." (4.) *Redargutio Philosophiarum,* a highly finished piece in the form of an oration, composed probably about 1608 or 1609, and containing in pretty full detail much of what afterwards appears in connection with the *Idola Theatri* in book i. of the *Novum Organum.* (5.) *Cogitata et Visa,* perhaps the most important of the minor philosophical writings, dating from 1607 (though possibly the tract in its present form may have been to some extent altered), and containing in weighty and sonorous Latin the substance of the first book of the *Organum.* (6.) The *Descriptio Globi Intellectualis,* which is to some extent intermediate between the *Advancement* and the *De Augmentis,* goes over in detail the general classification of the sciences, and enters particularly on some points of minor interest. (7.) The brief tract *De Interpretatione Naturæ Sententiæ Duodecim* is evidently a first sketch of part of the *Novum Organum,* and in phraseology is almost identical with it. (8.) A few smaller pieces, such as the *Inquisitio de Motu,* the *Calor et Frigus,* the *Historia Soni et Auditus,* and the *Phænomena Universi,*

[1] The peculiarities of Bacon's style were noticed very early by his contemporaries. (See *Letters and Life,* i. 268.) Raleigh and Jonson have both recorded their opinions of it, but no one, it seems to us, has characterised it more happily than his friend, Sir Tobie Matthews, "A man so rare in knowledge, of so many several kinds, endued with the facility and felicity of expressing it all in so elegant, significant, so abundant, and yet so choice and ravishing a way of words, of metaphors, of allusions, as perhaps the world hath not seen since it was a world."—"Address to the Reader" prefixed to *Collection of English Letters,* 1660.

are early specimens of his *Natural History*, and exhibit the first tentative applications of the new method.

The third great division of the philosophical works consists of treatises on subjects connected with the *Instauratio*, but not forming part of it. It is not necessary to characterise these at any length. The most interesting, and in many respects the most remarkable, is the philosophic romance, the *New Atlantis*, a description of an ideal state in which the principles of the new philosophy are carried out by political machinery, and under state guidance, and where many of the results contemplated by Bacon are in imagination attained. The work was to have been completed by the addition of a second part, treating of the laws of a model commonwealth, which was never written. Another important tract is the *De Principiis atque Originibus secundum Fabulas Cupidinis et Cœli*, where, under the disguise of two old mythological stories, he (in the manner of the *Sapientia Veterum*) finds the deepest truths concealed. The tract is unusually interesting, for in it he discusses at some length the limits of science, the origin of things, and the nature of primitive matter, giving at the same time full notices of Democritus among the ancient philosophers and of Telesius among the modern. Deserving of attention are also the *Cogitationes de Natura Rerum*, probably written early, perhaps in 1605, and the treatise on the theory of the tides, *De Fluxu et Refluxu Maris*, written probably about 1616.

The philosophical works which form part of the *Instauratio* must of course be classed according to the positions which they respectively hold in that scheme of the sciences. Before entering on an account of Bacon's object and method, it is necessary to give the general outline of his arrangement.

The great work, the reorganisation of the sciences, and the restoration of man to that command over nature which he had lost by the fall, consisted in its final form of six divisions.

I. *Partitiones Scientiarum*, a survey of the sciences, either such as then existed or such as required to be constructed afresh—in fact, an inventory of all the possessions of the human mind. The famous classification [1] on which this survey proceeds is based upon an analysis of the faculties and objects of human knowledge. This division is represented by the *De Augmentis Scientiarum*.

II. *Interpretatio Naturæ*.—After the survey of all that has yet been done in the way of discovery or invention, comes the new method, by which the mind of man is to be trained and directed in its progress towards the renovation of science. This division is represented, though only imperfectly, by the *Novum Organum*, particularly book ii.

III. *Historia Naturalis et Experimentalis*.—The new method is valueless, because inapplicable, unless it be supplied with materials duly collected and presented—in fact, unless there be formed a competent natural history of the *Phænomena Universi*. A short introductory sketch of the requisites of such a natural history, which, according to Bacon, is essential, necessary, the *basis totius negotii*, is given in the tract *Parasceve*, appended to the *Novum Organum*. The principal works intended to form portions of the history, and either published by himself or left in manuscript, are *Historia Ventorum*, *Historia Vitæ et Mortis*, *Historia Densi et Rari*, and the extensive collection of facts and observations entitled *Sylva Sylvarum*.

IV. *Scala Intellectus*.—It might have been supposed that the new philosophy could now be inaugurated. Materials had been supplied, along with a new method by which they were to be treated, and naturally the next step would be the finished result. But for practical purposes Bacon interposed two divisions between the preliminaries and the philosophy itself. The first was intended to consist of types or examples of investigations conducted by the new method, serviceable for keeping the whole process vividly before the mind, or, as the title indicates, such that the mind could run rapidly up and down the several steps or grades in the process. Of this division there seems to be only one small fragment, the *Filum Labyrinthi*, consisting of but two or three pages.

V. *Prodromi*, forerunners of the new philosophy. This part, strictly speaking, is quite extraneous to the general design. According to the *Distributio Operis*,[2] it was to contain certain speculations of Bacon's own, not formed by the new method, but by the unassisted use of his understanding. These, therefore, form temporary or uncertain anticipations of the new philosophy. There is extant a short preface to this division of the work, and according to Mr Spedding, some of the miscellaneous treatises, such as *De Principiis*, *De Fluxu et Refluxu*, *Cogitationes de Natura Rerum*, may probably have been intended to be included under this head. This supposition receives some support from the manner in which the fifth part is spoken of in the *Novum Organum*, i. 116.

VI. The new philosophy, which is the work of future ages, and the result of the new method.

Bacon's grand motive in his attempt to found the sciences anew was the intense conviction that the knowledge man possessed was of little service to him. "The knowledge whereof the world is now possessed, especially that of nature, extendeth not to magnitude and certainty of works." [3] Man's sovereignty over nature, which is founded on knowledge alone, had been lost, and instead of the free relation between things and the human mind, there was nothing but vain notions and blind experiments. To restore the original commerce between man and nature, and to recover the *imperium hominis*, is the grand object of all science. The want of success which had hitherto attended efforts in the same direction had been due to many causes, but chiefly to the want of appreciation of the nature of philosophy and its real aim. Philosophy is not the science of things divine and human; it is not the search after truth. "I find that even those that have sought knowledge for itself, and not for benefit or ostentation, or any practical enablement in the course of their life, have nevertheless propounded to themselves a wrong mark, namely, satisfaction (which men call Truth) and not operation." [4] "Is there any such happiness as for a man's mind to be raised above the confusion of things, where he may have the prospect of the order of nature and error of man? But is this a view of delight only and not of discovery? of contentment and not of benefit? Shall he not as well discern the riches of nature's warehouse as the beauty of her shop? Is truth ever barren? Shall he not be able thereby to produce worthy effects, and to endow the life of man with infinite commodities?" [5] Philosophy is altogether practical; it is of little matter to the fortunes of humanity what abstract notions one may entertain concerning the nature and the principles of things.[6] This truth, however, has never yet been recognised;[7] it has not yet been seen that the true aim of all science is "to endow the condition and life of man with

[1] As is well known, the division of the sciences adopted in the great French *Encyclopédie* was founded upon this classification of Bacon's. See Diderot's *Prospectus* (*Œuvres*, iii.) and D'Alembert's *Discours* (*Œuvres*, i.) The scheme should be compared with later attempts of the same nature by Ampère, Cournot, Comte, and H. Spencer.

new powers or works,"[1] or "to extend more widely the limits of the power and greatness of man."[2] Nevertheless, it is not to be imagined that by this being proposed as the great object of search there is thereby excluded all that has hitherto been looked upon as the higher aims of human life, such as the contemplation of truth. Not so, but by following the new aim we shall also arrive at a *true* knowledge of the universe in which we are, for without knowledge there is no power; truth and utility are in ultimate aspect the same; "works themselves are of greater value as pledges of truth than as contributing to the comforts of life."[3] Such was the conception of philosophy with which Bacon started, and in which he felt himself to be thoroughly original. As his object was new and hitherto unproposed, so the method he intended to employ was different from all modes of investigation hitherto attempted. "It would be," as he says, "an unsound fancy and self-contradictory, to expect that things which have never yet been done can be done except by means which have never yet been tried."[4] There were many obstacles in his way, and he seems always to have felt that the first part of the new scheme must be a *pars destruens*, a destructive criticism of all other methods. Opposition was to be expected, not only from previous philosophies, but especially from the human mind itself. In the first place, natural antagonism might be looked for from the two opposed sects, the one of whom, in despair of knowledge, maintained that all science was impossible; while the other, resting on authority and on the learning that had been handed down from the Greeks, declared that science was already completely known, and consequently devoted their energies to methodising and elaborating it. Secondly, within the domain of science itself, properly so called, there were two "kinds of rovers" who must be dismissed. The first were the speculative or logical philosophers, who construe the universe *ex analogia hominis*, and not *ex analogia mundi*, who fashion nature according to preconceived ideas, and who employ in their investigations syllogism and abstract reasoning. The second class, who were equally offensive, consisted of those who practised blind experience, which is mere groping in the dark (*vaga experientia mera palpatio est*), who occasionally hit upon good works or inventions, which, like Atalanta's apples, distracted them from further steady and gradual progress towards universal truth. In place of these straggling efforts of the unassisted human mind, a graduated system of helps was to be supplied, by the use of which the mind, when placed on the right road, would proceed with unerring and mechanical certainty to the invention of new arts and sciences.

Such were to be the peculiar functions of the new method, though it has not definitely appeared what that method was, or to what objects it could be applied. But, before proceeding to unfold his method, Bacon found it necessary to enter in considerable detail upon the general subject of the obstacles to progress, and devoted nearly the whole of the first book of the *Organum* to the examination of them. This discussion, though strictly speaking extraneous to the scheme, has always been looked upon as a most important part of his philosophy, and his name is perhaps as much associated with the doctrine of *Idola* as with the theory of induction or the classification of the sciences.

The doctrine of the kinds of fallacies or general classes of errors into which the human mind is prone to fall, appears in many of the works written before the *Novum Organum*, and the treatment of them varies in some respects. The classification in the *Organum*, however, not only has the author's sanction, but has received the stamp of historical acceptation; and comparison of the earlier notices, though a point of literary interest, has no important philosophic bearing. The *Idola*,[5] false notions of things, or erroneous ways of looking at nature, are of four kinds: the first two innate, pertaining to the very nature of the mind and not to be eradicated; the third creeping insensibly into men's minds, and hence in a sense innate and inseparable; the fourth imposed from without. The first kind are the *Idola Tribus*, fallacies incident to humanity or the race in general. Of these, the most prominent are—the proneness of the mind to suppose in nature greater order and regularity than there actually is; the tendency to support a preconceived opinion by affirmative instances, neglecting or throwing out of account all negative or opposed cases; and the tendency to generalise from few observations, or to give reality to mere abstractions, figments of the mind. Manifold errors also result from the weakness of the senses, which affords scope for mere conjecture; from the influence exercised over the understanding by the will and passions; from the restless desire of the mind to penetrate to the ultimate principles of things; and from the belief that "man is the measure of the universe," whereas, in truth, the world is received by us in a distorted and erroneous manner. The second kind are the *Idola Specus*, idols of the cave, or errors incident to the peculiar mental or bodily constitution of each individual, for according to the state of the individual's mind is his view of things. Errors of this class are innumerable, because there are numberless varieties of disposition; but some very prominent specimens can be indicated. Such are the tendency to make all things subservient to, or take the colour of some favourite subject, the extreme fondness and reverence either for what is ancient or for what is modern, and excess in noting either differences or resemblances amongst things. A practical rule for avoiding these is also given: "In general let every student of nature take this as a rule, that whatever his mind seizes and dwells upon with particular satisfaction is to be held in suspicion."[6] The third class are the *Idola Fori*, idols of the market-place, *i.e.*, errors arising from the influence exercised over the mind by mere words. This, according to Bacon, is the most troublesome kind of error, and has been especially fatal in philosophy. For words introduce a fallacious mode of looking at things in two ways: first, there are some words that are really merely names for non-existent things, which are yet supposed to exist simply because they have received a name; secondly, there are names hastily and unskilfully abstracted from a few objects and applied recklessly to all that has the faintest analogy with these objects, thus causing the grossest confusion. The fourth and last class are the *Idola Theatri*, idols of the theatre, *i.e.*, fallacious modes of thinking resulting from received systems of philosophy, and from erroneous methods of demonstration. The criticism of the demonstrations is introduced later in close connection with Bacon's new method; they are the rival modes of procedure, to which his own is definitely opposed. The philosophies which are "redargued" are divided into three classes, the sophistical, of which the best example is Aristotle, who forces nature into his abstract schemata and thinks to ex-

[1] *Fil. Lab.*, 5; *cf. N. O.*, i. 81; *Val. Ter.* (*Works*, iii. 222, 233); *New Atlantis* (*Works*, iii. 156).
[2] *N. O.*, i. 116. [3] *Ibid.*, i. 124. [4] *Ibid.*, i. 6.

[5] The word *Idolon* is manifestly borrowed from Plato. It is used twice in connection with the Platonic Ideas (*N. O.*, i. 23, 124), and is contrasted with them as the false appearance. The εἴδωλον with Plato is the fleeting, transient image of the real thing, and the passage evidently referred to by Bacon is that in the *Rep.* vii. 516 A. "καὶ πρῶτον μὲν τὰς σκιὰς ἂν ῥᾷστα καθορῴη, καὶ μετὰ τοῦτο ἐν τοῖς ὕδασι τά τε τῶν ἀνθρώπων καὶ τὰ τῶν ἄλλων εἴδωλα, ὕστερον δὲ αὐτά." It is explained well in the *Advancement*, bk. i. (*Works*, iii. 287).
[6] *N. O.*, i. 58.

plain by definitions; the empirical, which from few and limited experiments leaps at once to general conclusions; and the superstitious, which corrupts philosophy by the introduction of poetical and theological notions.

Such are the general causes of the errors that infest the human mind; by their exposure the way is cleared for the introduction of the new method. The nature of this method cannot be understood until it is exactly seen to what it is to be applied. What idea had Bacon of science, and how is his method connected with it? Now, the science[1] which was specially and invariably contemplated by him was Natural Philosophy, the great mother of all the sciences; it was to him the type of scientific knowledge, and its method was the method of all true science. To discover exactly the characteristics and the object of natural philosophy it is necessary to examine the place it holds in the general scheme furnished in the *Advancement* or *De Augmentis*. All human knowledge, it is there laid down, may be referred to man's memory, or imagination, or reason. In the first, the bare facts presented to sense are collected and stored up; the exposition of them is History, which is either natural or civil. In the second, the materials of sense are separated or divided in ways not corresponding to nature but after the mind's own pleasure, and the result is Poesy or feigned history. In the third, the materials are worked up after the model or pattern of nature, though we are prone to err in the progress from sense to reason; the result is Philosophy, which is concerned either with God, with nature, or with man, the second being the most important. Natural philosophy is again divided into speculative or theoretical, and operative or practical, according as the end is contemplation or works. Speculative or theoretical natural philosophy has to deal with natural substances and qualities, and is subdivided into physics and metaphysics. Physics inquires into the efficient and material causes of things; metaphysics, into the formal and final causes. The principal objects of physics are concrete substances, or abstract though physical qualities. The research into abstract qualities, the fundamental problem of physics, comes near to the metaphysical study of *forms*, which indeed differs from the first only in being more general, and in having as its result a *form* strictly so called, *i.e.*, a nature or quality which is a limitation or specific manifestation of some higher and better known genus. Natural philosophy is, therefore, in ultimate resort the study of *forms*, and, consequently, the fundamental problem of philosophy in general is the discovery of these *forms*.

"On a given body to generate or superinduce a new nature or natures, is the work and aim of human power. . . . Of a given nature to discover the form or true specific difference, or nature-engendering nature (*natura naturans*) or source of emanation (for these are the terms which are nearest to a description of the thing), is the work and aim of human knowledge."[2]

The questions, then, whose answers give the key to the whole Baconian philosophy, may be put briefly thus—What are forms? and how is it that knowledge of them solves both the theoretical and the practical problem of science? Bacon himself, as may be seen from the passage quoted above, finds great difficulty in giving an adequate and exact definition of what he means by a form. As a general description, the following passage from the *Novum Organum*, ii. 4, may be cited:—

"The form of a nature is such that given the form the nature infallibly follows. . . . Again, the form is such that if it be taken away the nature infallibly vanishes. . . . Lastly, the true form is such that it deduces the given nature from some source of being which is inherent in more natures, and which is better known in the natural order of things than the form itself."[3]

From this it would appear that, since by a *nature* is meant some sensible quality, superinduced upon, or possessed by, a body, so by a form we are to understand the cause of that nature, which cause is itself a determinate case or manifestation of some general or abstract quality inherent in a greater number of objects. But all these are mostly marks by which a form may be recognised, and do not explain what the form really is. A further definition is accordingly attempted in Aph. 13:—

"The form of a thing is the very thing itself, and the thing differs from the form no otherwise than as the apparent differs from the real, or the external from the internal, or the thing in reference to the man from the thing in reference to the universe."

This throws a new light on the question, and from it the inference at once follows, that the forms are the permanent causes or substances underlying all visible phenomena, which are merely manifestations of their activity. Are the forms, then, forces? At times it seems as if Bacon had approximated to this view of the nature of things, for in several passages he identifies forms with laws of activity. Thus, he says—

"When I speak of forms I mean nothing more than those laws and determinations of absolute actuality which govern and constitute any simple nature, as heat, light, weight, in every kind of matter and subject that is susceptible of them. Thus the form of heat or the form of light is the same thing as the law of heat or the law of light."[4] "Matter rather than forms should be the object of our attention, its configurations and changes of configuration, and simple action, and law of action or motion; for forms are figments of the human mind, unless you will call those laws of action forms."[5] "Forms or true differences of things, which are in fact laws of pure act."[6] "For though in nature nothing really exists besides individual bodies, performing pure individual acts according to a fixed law, yet in philosophy this very law, and the investigation, discovery, and explanation of it, is the foundation as well of knowledge as of operation. And it is this law, with its clauses, that I mean when I speak of forms."[7]

Several important conclusions may be drawn from these passages. In the first place, it is evident that Bacon, like the Atomical school, of whom he highly approved, had a clear perception and a firm grasp of the *physical* character of natural principles; his *forms* are no ideas or abstractions, but highly general physical properties. Further, it is hinted that these general qualities may be looked upon as the modes of action of simple bodies. This fruitful conception, however, Bacon does not work out; and though he uses the word cause, and identifies form with formal cause, yet it is perfectly apparent that the modern notions of cause as dynamical, and of nature as in a process of flow or development, are foreign to him, and that in his view of the ultimate problem of science, cause meant *causa immanens*, or underlying substance, effects were not consequents but manifestations, and nature was regarded in a purely statical aspect. That this is so appears even more clearly when we examine his general conception of the unity, gradation, and function of the sciences. That the sciences are organically connected is a thought common to him and to his distinguished predecessor Roger Bacon. "I that hold it for a great impediment towards the advancement and further invention of knowledge, that particular arts and sciences have been disincorporated from general knowledge, do not understand one and the same thing which Cicero's discourse and the note and conceit of the Grecians in their word *circle learning* do intend. For I mean not that use which one science hath of another for ornament or help in practice; but I mean it directly of that use by way of supply of light and information, which the particulars and instances of one science do yield and present for the framing or correcting of the axioms of an-

[1] *N. O.*, i. 79, 80, 98, 108. [2] *Ibid.*, ii. 1.
[3] This *better known in the order of nature* is nowhere satisfactorily explained by Bacon. Like his classification of causes, and in some degree his notion of form itself, it comes from Aristotle. See *An. Post.*, 71, *b* 33; *Topic*, 141, *b* 5; *Eth. Nic.*, 1095, *a* 30.
[4] *N. O.*, ii. 17. [5] *Ibid.*, i. 51. [6] *Ibid.*, i. 75. [7] *Ibid.*, ii. 2.

other science in their very truth and notion."[1] In accordance with this, Bacon placed at the basis of the particular sciences which treat of God, nature, and man, one fundamental doctrine, the *Prima Philosophia*, or first philosophy, the function of which was to display the unity of nature by connecting into one body of truth such of the highest axioms of the subordinate sciences as were not special to one science, but common to several.[2] This first philosophy had also to investigate what are called the adventitious or transcendental conditions of essences, such as Much, Little, Like, Unlike, Possible, Impossible, Being, Nothing, the logical discussion of which certainly belonged rather to the laws of reasoning than to the existence of things, but the physical or real treatment of which might be expected to yield answers to such questions as, Why certain substances are numerous, others scarce? or why, if like attracts like, iron does not attract iron? Following this summary philosophy come the sciences proper, rising like a pyramid in successive stages, the lowest floor being occupied by natural history or experience, the second by physics, the third, which is next the peak of unity, by metaphysics.[3] The knowledge of the peak, or of the one law which binds nature together, is perhaps denied to man. Of the sciences, physics, as has been already seen, deals with the efficient and material, *i.e.*, with the variable and transient, causes of things. But its inquiries may be directed either towards concrete bodies or towards abstract qualities. The first kind of investigation rises little above mere natural history; but the other is more important, and paves the way for metaphysics. It handles the configurations and the appetites or motions of matter. The configurations, or inner structures of bodies, include dense, rare, heavy, light, hot, cold, &c., in fact, what are elsewhere called simple natures. Motions[4] are either simple or compound, the latter being the sum of a number of the former. In physics, however, these matters are treated only as regards their material or efficient causes, and the result of inquiry into any one case gives no general rule, but only facilitates invention in some similar instance. Metaphysics, on the other hand, treats of the formal or final cause[5] of these same substances and qualities, and results in a general rule. With regard to forms, the investigation may be directed either towards concrete bodies or towards qualities. But the forms of substances "are so perplexed and complicated, that it is either vain to inquire into them at all, or such inquiry as is possible should be put off for a time, and not entered upon till forms of a more simple nature have been rightly investigated and discussed."[6] "To inquire into the form of a lion, of an oak, of gold, nay, even of water or air, is a vain pursuit; but to inquire the *form* of dense, rare, hot, cold, &c., as well configurations as motions, which in treating of physic I have in great part enumerated (I call them forms of the first class), and which (like the letters of the alphabet) are not many, and yet make up and sustain the essences and forms of all substances—this, I say, it is which I am attempting, and which constitutes and defines that part of metaphysic of which we are now inquiring." Physics inquires into the same qualities, but does not push its investigations into ultimate reality or reach the more general causes. We thus at last attain a definite conclusion with regard to forms, and it appears clear that in Bacon's belief the true function of science was the search for a few fundamental physical qualities, highly abstract and general, the combinations of which give rise to the simple natures and complex phenomena around us. His general conception of the universe may therefore be called mechanical or statical; the cause of each phenomenon is supposed to be actually contained in the phenomenon itself, and by a sufficiently accurate process could be sifted out and brought to light. As soon as the causes are known man regains his power over nature, for "whosoever knows any form, knows also the utmost possibility of superinducing that nature upon every variety of matter, and so is less restrained and tied in operation either to the basis of the matter or to the condition of the efficients."[7]

Nature thus presented itself to Bacon's mind as a huge congeries of phenomena, the manifestations of some simple and primitive qualities, which were hid from us by the complexity of the things themselves. The world was a vast labyrinth, amid the windings of which we require some clue or thread whereby we may track our way to knowledge and thence to power. This thread, the *filum labyrinthi*, is the new method of induction. But, as has been frequently pointed out, the new method could not be applied until facts had been observed and collected. This is an indispensable preliminary. "Man, the servant and interpreter of nature, can do and understand so much, and so much only, as he has observed in fact or in thought of the course of nature; beyond this he neither knows anything nor can do anything." The proposition that our knowledge of nature necessarily begins with observation and experience, is common to Bacon and many contemporary reformers of science, but he laid peculiar stress upon it, and gave it a new meaning. What he really meant by observation was a competent natural history or collection of facts. "The firm foundations of a purer natural philosophy are laid in natural history."[8] "First of all we must prepare a *natural and experimental history*, sufficient and good; and this is the foundation of all."[9] The senses and the memory, which collect and store up facts, must be assisted; there must be a *ministration* of the senses and another of the memory. For not only are instances required, but these must be arranged in such a manner as not to distract or confuse the mind, *i.e.*, tables and arrangements of instances must be constructed. In the preliminary collection the greatest care must be taken that the mind be absolutely free from preconceived ideas; nature is only to be conquered by obedience; man must be merely receptive. "All depends on keeping the eye steadily fixed upon the facts of nature, and so receiving their images simply as they are; for God forbid that we should give out a dream of our own imagination for a pattern of the world; rather may He graciously grant to us to write an apocalypse or true vision of the footsteps of the Creator imprinted on his creatures."[10] Concealed among the facts presented to sense are the causes or forms, and

[1] *Valerius Terminus*, iii. 228–29.

[2] *Cf. N. O.*, ii. 27. Bacon nowhere enters upon the questions of how such a science is to be constructed, and how it can be expected to possess an independent method while it remains the mere receptacle for the generalisations of the several sciences, and consequently has a content which varies with their progress. His whole conception of *Prima Philosophia* should be compared with such a modern work as the *First Principles* of Herbert Spencer.

[3] It is to be noticed that this scale of nature corresponds with the scale of ascending axioms.

[4] *Cf.* also, for motions, *N. O.*, ii. 48.

[5] The knowledge of final causes does not lead to works, and the consideration of them must be rigidly excluded from physics. Yet there is no opposition between physical and final causes; in ultimate resort the mind is compelled to think the universe as the work of reason, to refer facts to God and Providence. The idea of final cause is also fruitful in sciences which have to do with human action. (*Cf. De Aug.*, iii. cc. 4, 5; *Nov. Org.*, i. 48, ii. 2.)

[6] *De Aug.*, iii. 4. In the *Advancement* (*Works*, iii. 355) it is distinctly said that they are not to be inquired into. One can hardly see how the Baconian method could have applied to concrete substances.

[7] Thus the last step in the theoretical analysis gives the first means for the practical operation. *Cf.* Aristotle, *Eth. Nic.*, iii. 3, 12, "τὸ ἔσχατον ἐν τῇ ἀναλύσει πρῶτον εἶναι ἐν τῇ γενέσει." *Cf.* also *Nov. Org.*, i. 103.

[8] *Cogitationes* (*Works*, iii. 187).

[9] *N. O.*, ii. 10.

[10] Pref. to *Instaur.* *Cf. Valerius Term.* (*Works*, iii. 224), and *N. O.*, i. 68, 124.

the problem therefore is so to analyse experience,[1] so to break it up into pieces, that we shall with certainty and mechanical ease arrive at a true conclusion. This process, which forms the essence of the new method, may in its entirety, as a ministration to the reason, be called a logic; but it differs widely from the ordinary or school logic in end, method, and form. Its aim is to acquire command over nature by knowledge, and to invent new arts, whereas the old logic strove only after dialectic victories and the discovery of new arguments. In method the difference is even more fundamental. Hitherto the mode of demonstration had been by the syllogism; but the syllogism is, in many respects, an incompetent weapon. It is compelled to accept its first principles on trust from the science in which it is employed; it cannot cope with the subtlety of nature; and it is radically vitiated by being founded on hastily and inaccurately abstracted notions of things. For a syllogism consists of propositions, propositions of words, and words are the symbols of notions. Now the first step in accurate progress from sense to reason, or true philosophy, is to frame a *bona notio* or accurate conception of the thing; but the received logic never does this. It flies off at once from experience and particulars to the highest and most general propositions, and from these descends, by the use of middle terms, to axioms of lower generality. Such a mode of procedure may be called *anticipatio naturæ* (for in it reason is allowed to prescribe to things), and is opposed to the true method, the *interpretatio naturæ*, in which reason follows and obeys nature, discovering her secrets by obedience and submission to rule. Lastly, the very form of induction that has been used by logicians in the collection of their instances is a weak and useless thing. It is a mere enumeration of a few known facts, makes no use of exclusions or rejections, concludes precariously, and is always liable to be overthrown by a negative instance.[2] In radical opposition to this method the Baconian induction begins by supplying helps and guides to the senses, whose unassisted information could not be relied on. Notions were formed carefully, and not till after a certain process of induction was completed.[3] The formation of axioms was to be carried on by a gradually ascending scale. "Then and only then may we hope well of the sciences, when in a just scale of ascent and by successive steps, not interrupted or broken, we rise from particulars to lesser axioms; and then to middle axioms, one above the other; and last of all to the most general."[4] Finally the very form of induction itself must be new. "The induction which is to be available for the discovery and demonstration of sciences and arts must analyse nature by proper rejections and exclusions; and then, after a sufficient number of negatives, come to a conclusion on the affirmative instances, which has not yet been done, or even attempted, save only by Plato.[5] . . . And this induction must be used not only to discover axioms, but also in the formation of notions."[6] This view of the function of exclusion is closely connected with Bacon's doctrine of forms, and is in fact dependent upon that theory. But induction is neither the whole of the new method, nor is it applicable to forms only. There are two other grand objects of inquiry: the one, the transformation of concrete bodies; the other, the investigation of the latent powers and the latent schematism or configuration. With regard to the first, in ultimate result it depends upon the theory of forms; for whenever the compound body can be regarded as the sum of certain simple natures, then our knowledge of the forms of these natures gives us the power of superinducing a new nature on the concrete body. As regards the latent process which goes on in all cases of generation and continuous development or motion, we examine carefully, and by quantitative measurements, the gradual growth and change from the first elements to the completed thing. The same kind of investigation may be extended to many cases of natural motion, such as voluntary action or nutrition; and though inquiry is here directed towards concrete bodies, and does not therefore penetrate so deeply into reality as in research for forms, yet great results may be looked for with more confidence. It is to be regretted that Bacon did not complete this portion of his work, in which for the first time he approaches modern conceptions of change. The latent configuration or inward structure of the parts of a body must be known before we can hope to superinduce a new nature upon it. This can only be discovered by analysis, which will disclose the ultimate constituents (natural particles, not atoms) of bodies, and lead back the discussion to forms or simple natures, whereby alone can true light be thrown on these obscure questions. Thus, in all cases, scientific explanation depends upon knowledge of forms; all phenomena or secondary qualities are accounted for by being referred to the primary qualities of matter.

The several steps in the inductive investigation of the form of any nature flow readily from the definition of the form itself. For that is always and necessarily present when the nature is present, absent when it is absent, decreases and increases according as the nature decreases and increases. It is therefore requisite for the inquiry to have before us instances in which the nature is present. The list of these is called the table of *Essence and Presence*. Secondly, we must have instances in which the nature is absent; only as such cases might be infinite, attention should be limited to such of them as are most akin to the instances of presence.[7] The list in this case is called table of *Absence in Proximity*. Thirdly, we must have a number of instances in which the nature is present in different degrees, either increasing or decreasing in the same subject, or variously present in different subjects. This is the table of *Degrees* or of *Comparison*. After the formation of these tables, we proceed to apply what is perhaps the most valuable part of the

---

[1] Pref. to *Inst.*

[2] Bacon's summary is valuable. "In the whole of the process which leads from the senses and objects to axioms and conclusions, the demonstrations which we use are deceptive and incompetent. The process consists of four parts, and has as many faults. In the first place, the impressions of the sense itself are faulty, for the sense both fails us and deceives us. But its shortcomings are to be supplied and its deceptions to be corrected. Secondly, notions are all drawn from the impressions of the sense, and are indefinite and confused, whereas they should be definite and distinctly bounded. Thirdly, the induction is amiss which infers the principles of sciences by simple enumeration, and does not, as it ought, employ exclusions and solutions (or separations) of nature. Lastly, that method of discovery and proof according to which the most general principles are first established, and then intermediate axioms are tried and proved by them, is the parent of error and the curse of all science."—(*N. O.*, i. 69.)

[3] *N. O.*, i. 105.

[4] *Ibid.*, i. 104; *cf.* i. 19–26.

[5] This extract gives an answer to the objection sometimes raised that Bacon is not original in his theory of induction. He certainly admits that Plato has used a method somewhat akin to his own; but it has frequently been contended that his induction is nothing more than the ἐπάγωγη of Aristotle (see Rémusat's *Bacon, &c.*, pp. 310–215, and for a criticism, Waddington, *Essais de Logique*, p. 261, *sqq.*) This seems a mistake. Bacon did not understand by induction the argument from particulars to a general proposition; he looked upon the exclusion and rejection, or upon *elimination*, as the essence of induction. To this process he was led by his doctrine of forms, of which it is the necessary consequence; it is the infallible result of his view of science and its problem, and is as original as that is. Whoever accepts Bacon's doctrine of cause must accept at the same time his theory of the way in which the cause may be sifted out from among the phenomena. It is evident that the Socratic search for the essence by an analysis of instances—an induction ending in a definition—has a strong resemblance to the Baconian inductive method.

[6] *N. O.*, i. 105.

[7] That is to say, differing in nothing save the absence of the nature under investigation.

Baconian method, and that in which the author took most pride, the process of exclusion or rejection. This elimination of the non-essential, grounded on the fundamental propositions with regard to forms, is the most important of Bacon's contributions to the logic of induction, and that in which, as he repeatedly says, his method differs from all previous philosophies. It is evident that if the tables were complete, and our notions of the respective phenomena clear, the process of exclusion would be a merely mechanical *counting out*, and would *infallibly* lead to the detection of the cause or form. But it is just as evident that these conditions can never be adequately fulfilled. Bacon saw that his method was impracticable (though he seems to have thought the difficulties not insuperable), and therefore set to work to devise new helps, *adminicula*. These he enumerates in ii., *Aph.* 21 :—*Prerogative Instances, Supports of Induction, Rectification of Induction, Varying the Investigation according to the Nature of the Subject, Prerogative Natures, Limits of Investigation, Application to Practice, Preparations for Investigation, the Ascending and Descending Scale of Axioms.* The remainder of the *Organum* is devoted to a consideration of the twenty-seven classes of Prerogative Instances, and, though it contains much that is both luminous and helpful, it adds little to our knowledge of what constitutes the Baconian method. On the other heads we have but a few scattered hints. But although the rigorous requirements of science could only be fulfilled by the employment of all these means, yet in their absence it was permissible to draw from the tables and the exclusion an hypothetical conclusion, the truth of which might be verified by the use of the other processes; such an hypothesis is called fantastically the First Vintage (*Vindemiatio*). The inductive method, so far as exhibited in the *Organum*, is exemplified by an investigation into the nature of heat.

Such was the method devised by Bacon, and to which he ascribed the qualities of absolute certainty and mechanical simplicity. But even supposing that this method were accurate and completely unfolded, it is evident that it could only be made applicable and produce fruit when the phenomena of the universe have been very completely tabulated and arranged. In this demand for a complete natural history, Bacon also felt that he was original, and he was deeply impressed with the necessity for it;[1] in fact, he seems occasionally to place an even higher value upon it than upon his *Organum*. Thus, in the preface to his series of works forming the third part of the *Instauratio*, he says: "It comes, therefore, to this, that my *Organum*, even if it were completed, would not without the *Natural History* much advance the *Instauration of the Sciences*, whereas the *Natural History* without the *Organum* would advance it not a little."[2] But a complete natural history is evidently a thing impossible, and in fact *a* history can only be collected by attending to the requirements of the *Organum*. This was seen by Bacon, and what may be regarded as his final opinion on the question is given in the important letter to Baranzano:—"With regard to the multitude of instances by which men may be deterred from the attempt, here is my answer. First, what need to dissemble? Either store of instances must be procured, or the business must be given up. All other ways, however enticing, are impassable. Secondly, the prerogatives of instances, and the mode of experimenting upon experiments of light (which I shall hereafter explain), will diminish the multitude of them very much. Thirdly, what matter, I ask, if the description of the instances should fill six times as many volumes as Pliny's *History*? . . . . For the true natural history is to take nothing except instances, connections, observations, and canons."[3] The *Organum* and the *History* are thus correlative, and form the two equally necessary sides of a true philosophy; by their union the new philosophy is produced.

Two questions may be put to any doctrine which professes to effect a radical change in philosophy or science. Is it original? Is it valuable? With regard to the first, it has been already pointed out that Bacon's induction or inductive method is distinctly his own, though it cannot and need not be maintained that the general spirit of his philosophy was entirely new.

The value of the method is a separate and more difficult question. It has been assailed on the most opposite grounds. Macaulay, while admitting the *accuracy* of the process, denied its efficiency, on the ground that an operation performed naturally was not rendered more easy or efficacious by being subjected to analysis.[4] This objection is curious when confronted with Bacon's reiterated assertion that the *natural* method pursued by the unassisted human reason is distinctly opposed to his; and it is besides an argument that tells so strongly against many sciences, as to be comparatively worthless when applied to any one. There are, however, more formidable objections against the method. It has been pointed out,[5] and with perfect justice, that science in its progress has not followed the Baconian method; that no one discovery can be pointed to which can be definitely ascribed to the use of his rules, and that men the most celebrated for their scientific acquirements, while paying homage to the name of Bacon, practically set at naught his most cherished precepts. The reason of this is not far to seek, and has been pointed out by logicians of the most diametrically opposed schools. The mechanical character both of the natural history and of the logical method applied to it, resulted necessarily from Bacon's radically false conception of the nature of cause and of the causal relation. The whole logical or scientific problem is treated as if it were one of co-existence, to which in truth the method of exclusion is scarcely applicable, and the assumption is constantly made that each phenomenon has one and only one cause.[6] The inductive formation of axioms by a gradually ascending scale is a route which no science has ever followed, and by which no science could ever make progress. The true scientific procedure is by hypothesis followed up and tested by verification; the most powerful instrument is the deductive method, which Bacon can hardly be said to have recognised. The power of framing

[4] Compare what Bacon says, *N. O.*, i. 130.

[5] Brewster, *Life of Newton*, 1855 (see particularly vol. ii. 403, 405); Lasson, *Ueber Bacon von Verulam's wissenschaftliche Principien*, 1860; Liebig, *Ueber Francis Bacon von Verulam*, &c., 1863 (a translation of the last appeared in *Macmillan's Magazine* for July and August 1863). Although Liebig points out how little science proceeds according to Bacon's rules, yet his o her criticisms seem of extremely little value. In a very offensive and quite unjustifiable tone, which is severely commen ed on by Sigwart and Fischer, he attacks the Baconian methods and its results. These results he claims to find in the *Sylva Sylvarum*, entirely ignoring what Bacon himself has said of the nature of that work (*N. O.*, i. 117; *cf.* Rawley's Pref. to the *S. S.*), and thus putting a false interpretation on the experiments the e noted. It is not surprising that he should detect many flaws, but he never fails to exaggerate an error, and seems sometimes completely to miss the point of what Bacon says. (See particularly his remarks on *S. S.*, 33, 336.) The method he explains in such a way as to show he has not a glimpse of its true nature. He brings against Bacon, of all men, the accusations of making induction start from the undetermined perceptions of the senses, of using imagination, and of putting a quite arbitrary interpretation on phenomena. He crowns his criticism by expounding what he considers to be the true scientific method, which, as has been pointed out by Fischer, is simply that Baconian doctrine against which his attack ought to have been directed. (See his account of the method, *Ueber Bacon*, 47–49; K. Fischer, *Bacon*, p. 499–502.)

[6] Mill, *Logic*, ii. pp. 115, 116, 329, 330.

hypotheses points to another want in the Baconian doctrine. If that power form part of the true method, then the mind is not wholly passive or recipient; it anticipates nature, and moulds the experience received by it in accordance with its own constructive ideas or conceptions; and yet further, the minds of various investigators can never be reduced to the same dead mechanical level.[1] There will still be room for the scientific use of the imagination, and for the creative flashes of genius.[2]

If, then, Bacon himself made no contributions to science, if no discovery can be shown to be due to the use of his rules, if his method be logically defective, and the problem to which it was applied one from its nature incapable of adequate solution, it may not unreasonably be asked, How has he come to be looked upon as the great leader in the reformation of modern science? How is it that he shares with Descartes the honour of inaugurating modern philosophy? To this the true answer seems to be, that Bacon owes his position not only to the general spirit of his philosophy, but to the manner in which he worked into a connected system the new mode of thinking, and to the incomparable power and eloquence with which he expounded and enforced it. Like all epoch-making works, the *Novum Organum* gave expression to ideas which were already beginning to be in the air. The time was ripe for a great change; scholasticism, long decaying, had begun to fall; the authority not only of school doctrines but of the church had been discarded; while here and there a few devoted experimenters were turning with fresh zeal to the unwithered face of nature. The fruitful thoughts which lay under and gave rise to these scattered efforts of the human mind, were gathered up into unity, and reduced to system in the new philosophy of Bacon.[3] It is assuredly little matter for wonder that this philosophy should contain much that is now inapplicable, and that in many respects it should be vitiated by radical errors. The details of the logical method on which its author laid the greatest stress have not been found of practical service;[4] yet the fundamental ideas on which the theory rested, the need for rejecting rash generalisation, and the necessity for a critical analysis of experience, are as true and valuable now as they were then. Progress in scientific discovery is made mainly, if not solely, by the employment of hypothesis, and for that no code of rules can be laid down such as Bacon had devised. Yet the framing of hypothesis is no mere random guess work; it is not left to the imagination alone, but to the *scientific imagination*. There is required in the process not merely a preliminary critical induction, but a subsequent experimental comparison, verification, or proof, the canons of which can be laid down with precision. To formulate and show grounds for these laws is to construct a philosophy of induction, and it must not be forgotten that the first step towards the accomplishment of the task was made by Bacon, when he introduced and gave due prominence to the powerful logical instrument of exclusion or elimination.

Of the general characteristics of Bacon's philosophy, and of the consequent place he holds in the history of modern speculative thought, this is not the place to speak. It is curious and significant that in the domain of the moral and metaphysical sciences his influence has been perhaps more powerful, and his authority has been more frequently appealed to, than in that of the physical. This is due, not so much to his expressed opinion that the inductive method was applicable to all the sciences,[5] as to the generally practical, or, one may say, *positive* spirit of his system. Theological questions, which had tortured the minds of generations, are by him relegated from the province of reason to that of faith. Even reason must be restrained from striving after ultimate truth; it is one of the errors of the human intellect that it will not rest in general principles, but must push its investigations deeper. Experience and observation are the only remedies against prejudice and error. Into questions of metaphysics as commonly understood Bacon can hardly be said to have entered, but a long line of thinkers have drawn inspiration from him, and it is not without justice that he has been looked upon as the originator and guiding spirit of that empirical school which numbers among its adherents such names as Hobbes, Locke, Hume, Hartley, Mill, Condillac, the Encyclopædists, and many others of smaller note.

In concluding this article, the writer desires to express his obligations to Mr James Spedding for various observations and suggestions made upon it before it went to press, and for the use of certain MS. notes relating to disputable passages in Bacon's life.

Biography.—Spedding, *Letters and Life of Lord Bacon*, 7 vols. 1862-74; Macaulay, *Essays*; Campbell, *Lives of Chancellors*; Montagu, *Works*, vols. xvi. and xvii., 1834; Hepworth Dixon, *Personal History of Lord Bacon*, 1861, and *Story of Lord Bacon's Life*, 1862.

Works.—The classical edition is that by Messrs R. L. Ellis, J. Spedding, and D. D. Heath, 2d ed., 7 vols., 1870 (i.-iii. contains Philosophical Works; iv. v., Translations; vi. vii., Literary and Professional Works). Montagu's edition (17 vols., 1825-34)

[1] Whewell, *Phil. of Ind. Sc.*, ii. 399, 402-3; Ellis, *Int. to Bacon's Works*, i. 39, 61; Brewster, *Newton*, ii. 404; Jevons, *Princ of Science*, ii. 220. A severe judgment on Bacon's method is given in Dühring's able but one-sided *Kritische Gesch. d. Phil.*, in which the merits of Roger Bacon are brought prominently forward.

[2] Although it must be admitted that the Baconian method is fairly open to the above-mentioned objections, it is curious and significant that Bacon was not thoroughly ignorant of them, but with deliberate consciousness preferred his own method. We do not think, indeed, that the *notiones* of which he speaks in any way correspond to what Whewell and Ellis would call "conceptions or ideas furnished by the mind of the thinker;" nor do we imagine that Bacon would have admitted these as necessary elements in the inductive process. But he was certainly not ignorant of what may be called a deductive method, and of a kind of hypothesis. This is clear from the use he makes of the *Vindemiatio*, from certain hints as to the testing of axioms, from his admission of the syllogism into physical reasoning, and from what he calls *Experientia Literata*. The function of the *Vindemiatio* has been already pointed out; with regard to axioms, he says (*N. O.*, i. 106), "In establishing axioms by this kind of induction, we must also examine and try whether the axiom so established be framed to the measure of these particulars from which it is derived, or whether it be larger or wider. And if it be larger and wider, we must observe whether, by indicating to us new particulars, it confirm that wideness and largeness as by a collateral security, that we may not either stick fast in things already known, or loosely grasp at shadows and abstract forms, not at things solid and realised in matter." (*Cf.* also the passage from *Valerius Terminus*, quoted in Ellis's note on the above aphorism.) Of the syllogism he says, "I do not propose to give up the syllogism altogether. S. is incompetent for the principal things rather than useless for the generality. In the mathematics there is no reason why it should not be employed. It is the flux of matter and the inconstancy of the physical body which requires induction, that thereby it may be fixed as it were, and allow the formation of notions well defined. In physics you wisely note, and therein I agree with you, that after the notions of the first class and the axioms concerning them have been by induction well made out and defined, syllogism may be applied safely; only it must be restrained from leaping at once to the most general notions, and progress must be made through a fit succession of steps."—("Letter to Baranzano," *Letters and Life*, vii. 377.) And with this may be compared what he says of mathematics (*Nov. Org.*, ii. 8; *Parasceve*, vii.) In his account of *Experientia Literata* (*De Aug.* v. 2) he comes very near to the modern mode of experimental research. It is, he says, the procedure from one experiment to another, and it is not a science, but an art or learned sagacity (resembling in this Aristotle's ἀγχίνοια), which may, however, be enlightened by the precepts of the *Interpretatio*. Eight varieties of such experiments are enumerated, and a comparison is drawn between this and the inductive method; "though the rational method of inquiry by the Organon promises far greater things in the end, yet this sagacity, proceeding by learned experience, will in the meantime present mankind with a number of inventions which lie near at hand." (*Cf. N. O.*, i. 103.)

[3] See the vigorous passage in Herschel, *Discourse on the Study of Natural Philosophy*, § 105; *cf.* § 96 of the same work.

[4] Bacon himself seems to anticipate that the progress of science would of itself render his method antiquated (*Nov. Org.*, i. 130).

[5] *Nov. Org.*, i. 127.

is full, but badly arranged and edited. Of numerous editions of individual works, or portions of the whole, the following are good:—*Œuvres Philosophiques de Bacon*, par Bouillet, 3 vols., 1834; *Essays*, by Whately, 5th ed., 1866, and by W. A. Wright, 1862; *Novum Organum*, by Kitchin (1855); Translation by the same (1855); *Advancement of Learning*, by W. A. Wright.

Philosophy.—Besides the Introductions in Ellis and Spedding's edition, the following may be noticed:—Kuno Fischer, *Franz Bacon und seine Nachfolger*, 2d ed., 1875 (1st ed., 1856, trans. into English by Oxenford, 1857); Rémusat, *Bacon, sa vie, &c.*, 1857 (2d ed., 1858); Craik, *Bacon, his Writings and his Philosophy*, 3 vols. 1846-7 (new ed., 1860); A. Dorner, *De Baconis Philosophia*, Berlin, 1867; Liebig, *Ueber Francis Bacon von Verulam und die Methode der Naturforschung*, 1863; Lasson, *Ueber Bacon von Verulam's wissenschaftliche Principien*, 1860; Böhmer, *Ueber F. Bacon von Verulam*, 1864. (R. AD.)

John. BACON, JOHN, who may be considered the founder of the British school of sculpture, was born Nov. 24, 1740. He was the son of Thomas Bacon, cloth-worker in Southwark, whose forefathers possessed a considerable estate in Somersetshire. At the age of fourteen he was bound apprentice in Mr. Crispe's manufactory of porcelain at Lambeth, where he was at first employed in painting the small ornamental pieces of china, but by his great skill in moulding he soon attained the distinction of being modeller to the work. The produce of his labour he devoted to the support of his parents, then in somewhat straitened circumstances. While engaged in the porcelain works he had an opportunity of seeing the models executed by different sculptors of eminence, which were sent to be burned at an adjoining pottery. An observation of these productions appears to have immediately determined the direction of his genius; he devoted himself to the imitation of them with so much success, that in 1758 a small figure sent by him to the Society for the Encouragement of Arts received a prize, and the highest premiums given by that society were adjudged to him nine times between the years 1763 and 1776. During his apprenticeship he also improved the method of working statues in artificial stone, an art which he afterwards carried to perfection. Bacon first attempted working in marble about the year 1763, and, during the course of his early efforts in this art, was led to improve the method of transferring the form of the model to the marble (technically called *getting out the points*), by the invention of a more perfect instrument for the purpose, which has since been adopted by many sculptors both in this and other countries. This instrument possesses many advantages above those formerly employed; it is more exact, takes a correct measurement in every direction, is contained in a small compass, and can be used upon either the model or the marble. In the year 1769 he was adjudged the first gold medal given by the Royal Academy, and in 1770 was made an associate of that body. He shortly afterwards exhibited a figure of Mars, which gained him considerable reputation, and he was then engaged to execute a bust of George III., intended for Christ Church, Oxford. He secured the king's favour, and retained it throughout life. His great celebrity now procured him numerous commissions, and it is said, that of sixteen different competitions in which he was engaged with other artists, he was unsuccessful in one case only. Considerable jealousy was entertained against him by other sculptors, and he was commonly charged with ignorance of classic style. This charge he repelled by the execution of a noble head of Jupiter Tonans, and many of his emblematical figures are in perfect classical taste. On the 4th of August 1799, he was suddenly attacked with inflammation, which occasioned his death in little more than two days, in the 59th year of his age. He left a widow, his second wife, and a family of six sons and three daughters. Of his merit as a sculptor, the universal reputation of his works affords decisive proof, and his various productions which adorn St Paul's Cathedral, London, Christ Church and Pembroke College, Oxford, the Abbey Church, Bath, and Bristol Cathedral, give ample testimony to his powers. Perhaps his best works are to be found among the monuments in Westminster Abbey. (See *Memoir of the late John Bacon, R.A.*, by the Rev. Richard Cecil: London, 1811.)

BACON, SIR NICHOLAS, lord keeper of the great seal in Nicholas. the reign of Queen Elizabeth, was born at Chislehurst in Kent in 1510, and educated at the university of Cambridge, after which he travelled in France, and made some stay at Paris. On his return he settled in Gray's Inn, and applied himself with such assiduity to the study of the law, that he quickly distinguished himself; and, on the dissolution of the monastery of St Edmund's Bury in Suffolk, he obtained a grant of several manors from King Henry VIII., then in the thirty-sixth year of his reign. Two years later he was promoted to the office of attorney in the court of wards, which was a place of both honour and profit. In this office he was continued by King Edward VI.; and in 1552 he was elected treasurer of Gray's Inn. His great moderation and prudence preserved him through the dangerous reign of Queen Mary. Very early in the reign of Elizabeth he was knighted; and in 1558 he succeeded Nicholas Heath, archbishop of York, as keeper of the great seal of England; he was at the same time made one of the queen's privy council. As a statesman, he was remarkable for the clearness of his views and the wisdom of his counsels, and he had a considerable share in the settling of ecclesiastical questions. That he was not unduly elated by his preferments, appears from the answer he gave to Queen Elizabeth when she told him his house at Redgrave was too little for him, "Not so," madam," returned he, "but your majesty has made me too great for my house." On only one occasion did he partially lose the queen's favour. He was suspected of having assisted Hales, the clerk of the hanaper, in his book on the succession, written at the time of Lady Catherine Grey's unjust imprisonment. Bacon was deprived of his seat at the council, and it was even contemplated to deprive him of the seal also. He seems, however, to have quickly regained his position, and to have stood as high in the royal favour as before. He died on the 26th of February 1579, having held the great seal more than twenty years, and was buried in St Paul's, London, where a monument, destroyed by the great fire of London in 1666, was erected to his memory. Granger observes that he was the first lord keeper who ranked as lord chancellor; and that he had much of that penetrating genius, solidity, judgment, persuasive eloquence, and comprehensive knowledge of law and equity which afterwards shone forth with such splendour in his illustrious son.

BACON, ROGER. The 13th century, an age peculiarly Roger. rich in great men, produced few, if any, who can take higher rank than Roger Bacon. He is in every way worthy to be placed beside such thinkers as Albertus Magnus, Bonaventura, and Thomas Aquinas. These had an infinitely wider renown in their day, while he was ignored by his contemporaries and neglected by his successors; but modern criticism has restored the balance in his favour, and is even in danger of going equally far in the opposite direction. Bacon, it is now said, was not appreciated by his age because he was so completely in advance of it; he is a 16th or 17th century philosopher, whose lot has been by some accident cast in the 13th century; he

Roger. is no schoolman, but a modern thinker, whose conceptions of science are more just and clear than are even those of his more celebrated namesake.[1] In this view there is certainly a considerable share of truth, but it is much exaggerated. As a general rule, no man can be completely dissevered from his national antecedents and surroundings, and Bacon is not an exception. Those who take up such an extreme position regarding his merits have known too little of the state of contemporary science, and have limited their comparison to the works of the scholastic theologians. We never find in Bacon himself any consciousness of originality; he has no fresh creative thought or method to introduce whereby the face of science may be changed; he is rather a keen and systematic thinker, who is working in a well-beaten track, from which his contemporaries were being drawn by the superior attractions of theology and metaphysics.

Roger Bacon was born in 1214, near Ilchester, in Somersetshire. His family appears to have been in good circumstances, for he speaks of his brother as wealthy, and he himself expended considerable sums on books and instruments; but in the stormy reign of Henry III. they suffered severely, their property was despoiled, and several members of the family were driven into exile. Roger completed his studies at Oxford, though not, as current traditions assert, at Merton or at Brazenose, neither of those colleges having then been founded. His great abilities were speedily recognised by his contemporaries, and he came to be on terms of close intimacy with some of the most independent thinkers of the time. Of these the most prominent were Adam de Marisco and Robert Grosseteste (*Capito*), afterwards bishop of Lincoln, a man of liberal mind and wide attainments, who had especially devoted himself to mathematics and experimental science.

Very little is known of Bacon's life at Oxford; it is said he took orders in 1233, and this is not improbable. In the following year, or perhaps later, he crossed over to France, and studied for a considerable length of time at the university of Paris, then the centre of intellectual life in Europe. The years Bacon spent there were unusually stirring. The two great orders, the Franciscans and Dominicans, were in the vigour of youth, and had already begun to take the lead in theological discussion. Alexander of Hales, the author of the great *Summa*, was the oracle of the Franciscans, while the rival order rejoiced in Albertus Magnus, and in the rising genius of the angelic doctor, Thomas Aquinas.

The scientific training which Bacon had received, partly by instruction, but more from the study of the Arab writers, made patent to his eyes the manifold defects in the imposing systems reared by these doctors. It disgusted him to hear from all around him that philosophy was now at length complete, that it had been reduced into compact order, and was being set forth by a certain professor at Paris. Even the great authority on which they reposed, Aristotle, was known but in part, and that part was rendered well-nigh unintelligible through the vileness of the translations; yet not one of those professors would learn Greek so that they might arrive at a real knowledge of their philosopher. The Scriptures, if read at all in the schools, were read in the erroneous versions; but even these were being deserted for the *Sentences* of Peter Lombard. Physical science, if there was anything deserving that name, was cultivated, not by experiment in the true Aristotelian way, but by discussion and by arguments deduced from premises resting on authority or custom. Everywhere there was a show of knowledge covering and concealing fundamental ignorance. Bacon, accordingly, who knew what true science was, and who had glimpses of a scientific *organon* or method, withdrew from the usual scholastic routine, and devoted himself to languages and experimental researches. Among all the instructors with whom he came in contact in Paris, only one gained his esteem and respect; this was an unknown individual, Petrus de Maharncuria Picardus, or of Picardy, probably identical with a certain mathematician, Petrus Peregrinus of Picardy, who is perhaps the author of a MS. treatise, *De Magnete*, contained in the Bibliothèque Impériale at Paris. The contrast between the obscurity of such a man and the fame enjoyed by the fluent young doctors of the schools seems to have roused Bacon's indignation. In the *Opus Minus* and *Opus Tertium* he pours forth a violent tirade against Alexander of Hales, and against another professor, not mentioned by name, but spoken of as alive, and blamed even more severely than Alexander. This anonymous writer, he says, who entered the order when young (*puerulus*), who had received no proper or systematic instruction in science or philosophy, for he was the first in his order to teach such subjects, acquired his learning by teaching others, and adopted a dogmatic tone, which has caused him to be received at Paris with applause as the equal of Aristotle, Avicenna, or Averroes. He has corrupted philosophy more than any other; he knows nothing of optics or perspective, and yet has presumed to write *de naturalibus*; he is ignorant of speculative alchemy, which treats of the origin and generation of things; he, indeed, is a man of infinite industry, who has read and observed much, but all his study is wasted because he is ignorant of the true foundation and method of science.[2]

It is probable that Bacon, during his stay in Paris, acquired considerable renown. He took the degree of doctor of theology, and seems to have received from his contemporaries the complimentary title of *doctor mirabilis*. In 1250 he was again at Oxford, and probably about this time, though the exact date cannot be fixed, he entered the Franciscan order. His fame spread very rapidly at Oxford, though it was mingled with suspicions of his dealings in magic and the black arts, and with some doubts of his orthodoxy. About 1257, Bonaventura, general of the order, interdicted his lectures at Oxford, and commanded him to leave that town and place himself under the superintendence of the body at Paris. Here for ten years he remained under constant supervision, suffering great privations, and strictly prohibited from writing anything which might be published. But during the time he had been at Oxford his fame had reached the ears of the Papal legate in England, Guy de Foulques, a man of culture and scientific tastes, who in 1265 was raised to the papal chair as Clement IV. In the following year he wrote to Bacon, who had been already in communication with him, ordering him, notwithstanding

[1] See Dühring, *Kritische Ges. d. Phil.*, 192, 249–51.

[2] It is difficult to identify this unknown professor. Brewer thinks the reference is to Richard of Cornwall; but the little we know of Richard is not in harmony with what is said here, nor with the terms in which he is elsewhere spoken of by Bacon. Erdmann conjectures Thomas Aquinas, which is extremely improbable, as Thomas was unquestionably not the first of his order to study philosophy. Cousin and Charles think that Albertus Magnus is aimed at, and certainly much of what is said applies with peculiar force to him. But some things do not at all cohere with what is otherwise known of Albert. The unknown is said to have received no regular philosophic training; we know that Albert did. The unknown entered the order when very young; unless the received date of Albert's birth be false, he did not enter till nearly twenty-eight years of age. Albert, too, could not be said with justice to be utterly ignorant of alchemy, and his mechanical inventions are well known. It is worth pointing out that Brewer, in transcribing the passage bearing on this (*Op. Ined.* p. 327), has the words *Fratrum Puerulus*, which in his marginal note he interprets as applying to the Franciscan order. In this case, of course, Albert could not be the person referred to, as he was a Dominican. But Charles, in his transcription, entirely omits the important word *Fratrum*. There are other instances in which Brewer and Charles do not agree, *e.g.*, according to Brewer, Bacon speaks of Thomas and Albert as *pueri duorum ordinum*; according to Charles, he says, *primi duorum ordinum*; a discrepancy not unimportant.

any injunctions from his superiors, to write out and send to him a treatise on the sciences which he had already asked of him when papal legate. Bacon, who in despair of being ever able to communicate his results to the world, had neglected to compose anything, and whose previous writings had been mostly scattered tracts, *capitula quædam*, took fresh courage from this command of the Pope. Relying on his powerful protection, he set at naught the many obstacles thrown in his way by the jealousy of his superiors and brother friars, and despite the want of funds, instruments, materials for copying, and skilled copyists, completed in about eighteen months three large treatises, the *Opus Majus*, *Opus Minus*, and *Opus Tertium*, which, with some other tracts, were despatched to the Pope by the hands of one Joannes, a young man trained and educated with great care by Bacon himself.

The composition of such extensive works in so short a time is a marvellous feat. We do not know what opinion Clement formed of them, but before his death he seems to have bestirred himself on Bacon's behalf, for in 1268 the latter was released and permitted to return to Oxford. Here he continued his labours in experimental science, and also in the composition of complete treatises. The works sent to Clement he regarded as mere preliminaries, laying down principles which were afterwards to be applied to the several sciences. The first part of an encyclopædic work probably remains to us in the *Compendium Studii Philosophiæ*, belonging to the year 1271. In this work Bacon makes a vehement attack upon the ignorance and vices of the clergy and monks, and generally upon the insufficiency of the existing studies. In 1278 he underwent the punishment which seems to have then been the natural consequence of outspoken opinions. His books were condemned by Jerome de Ascoli, general of the Franciscans, a gloomy bigot, who afterwards became Pope, and the unfortunate philosopher was thrown into prison, where he remained for fourteen years. During this time, it is said, he wrote the small tract *De Retardandis Senectutis Accidentibus*, but this is merely a tradition. In 1292, as appears from what is probably his latest composition, the *Compendium Studii Theologiæ*, he was again at liberty. The exact time of his death cannot be determined; 1294 is probably as accurate a date as can be fixed upon.

Bacon's Works.—Leland has said that it is easier to collect the leaves of the Sibyl than the titles of the works written by Roger Bacon; and though the labour has been somewhat lightened by the publications of Brewer and Charles, referred to below, it is no easy matter even now to form an accurate idea of his actual productions. His writings, so far as known to us, may be divided into two classes, those yet in manuscript and those printed. An enormous number of MSS. are known to exist in British and French libraries, and probably all have not yet been discovered. Many are transcripts of works or portions of works already published, and therefore require no notice. Of the others, several are of first-rate value for the comprehension of Bacon's philosophy, and, though extracts from them have been given by Charles, it is clear that till they have found an editor, no representation of his philosophy can be complete.[1]

The works hitherto printed (neglecting reprints) are the following:—(1.) *Speculum Alchimiæ*, 1541—translated into English, 1597; (2.) *De Mirabili Potestate Artis et Naturæ*, 1542—English translation, 1659; (3.) *Libellus de Retardandis Senectutis Accidentibus*, 1590—translated as the "Cure of Old Age," 1683; (4.) *Sanioris Medicinæ Magistri D. Rogeri Baconis Anglici de Arte Chymiæ Scripta*, 1603—a collection of small tracts containing *Excerpta de Libro Avicennæ de Anima*, *Breve Breviarium*, *Verbum Abbreviatum*,[2] *Secretum Secretorum*, *Tractatus Trium Verborum*, and *Speculum Secretorum*; (5.) *Perspectiva*, 1614, which is the fifth part of the *Opus Majus*; (6.) *Specula Mathematica*, which is the fourth part of the same; (7.) *Opus Majus ad Clementem IV.*, edited by Jebb, 1733; (8.) *Opera hactenus Inedita*, by J. S. Brewer, 1859, containing the *Opus Tertium*, *Opus Minus*, *Compendium Studii Philosophiæ*, and the *De Secretis Operibus Naturæ*. Roger.

How these works stand related to one another can only be determined by internal evidence, and this is a somewhat hazardous method. The smaller works, which are chiefly on alchemy, are unimportant, and the dates of their composition cannot be ascertained. It is known that before the *Opus Majus* Bacon had already written some tracts, among which an unpublished work, *Computus Naturalium*, on chronology, belongs probably to the year 1263; while, if the dedication of the *De Secretis Operibus* be authentic, that short treatise must have been composed before 1249.

It is, however, with the *Opus Majus* that Bacon's real activity begins. That great work, which has been called by Whewell at once the Encyclopædia and the Organum of the 13th century, requires a much fuller notice than can here be given. As published by Jebb it consists of six parts; there should, however, be a seventh, *De Morali Philosophia*, frequently referred to in the *Opus Tertium*. Part I. (pp. 1–22), which is sometimes designated *De Utilitate Scientiarum*, treats of the four *offendicula*, or causes of error. These are, authority, custom, the opinion of the unskilled many, and the concealment of real ignorance with show or pretence of knowledge. The last error is the most dangerous, and is, in a sense, the cause of all the others. The *offendicula* have sometimes been looked upon as an anticipation of the more celebrated doctrine of *Idola*; the two classifications, however, have little in common. In the summary of this part, contained in the *Opus Tertium*, Bacon shows very clearly his perception of the unity of science, and the necessity of an encyclopædical treatment. "Nam omnes scientiæ sunt annexæ, et mutuis se fovent auxiliis, sicut partes ejusdem totius, quarum quælibet opus suum peragit, non solum propter se, sed pro aliis."—(*Op. Ined.*, p. 18.)

Part II. (pp. 23–43) treats of the relation between philosophy and theology. All true wisdom is contained in the Scriptures, at least implicitly; and the true end of philosophy is to rise from the imperfect knowledge of created things to a knowledge of the Creator. Ancient philosophers, who had not the Scriptures, received direct illumination from God, and only thus can the brilliant results attained by them be accounted for.

Part III. (pp. 44–57) treats of the utility of grammar, and the necessity of a true linguistic science for the adequate comprehension either of the Scriptures or of books on philosophy. The necessity of accurate acquaintance with any foreign language, and of obtaining good texts, is a subject Bacon is never weary of descanting upon. He lays down very clearly the requisites of a good translator; he should know thoroughly the language he is translating

[1] The more important MSS. are:—(1.) The extensive work on the fundamental notions of physics, called *Communia Naturalium*, which is found in the Mazarin Library at Paris, in the British Museum, and in the Bodleian and University College Libraries at Oxford; (2.) On the fundamental notions of mathematics, *De Communibus Mathematicæ*, part of which is in the Sloane collection, part in the Bodleian; (3.) *Baconis Physica*, contained among the additional MSS. in the British Museum; (4.) The fragment called *Quinta Pars Compendii Theologiæ*, in the Brit. Mus.; (5.) The *Metaphysica*, in the Biblioth. Impér. at Paris; (6.) The *Compendium Studii Theologiæ*, in the Brit. Mus.; (7.) The logical fragments, such as the *Summa Dialectices*, in the Bodleian, and the glosses upon Aristotle's physics and metaphysics in the library at Amiens.

[2] At the close of the *Verb. Abbrev.* is a curious note, concluding with the words, "*ipse Rogerus fuit discipulus fratris Alberti!*"

from, the language into which he is translating, and the subject of which the book treats.

Part IV. (57–255) contains an elaborate treatise on mathematics, "the alphabet of philosophy," and on its importance in science and theology. Bacon shows at great length that all the sciences rest ultimately on mathematics, and progress only when their facts can be subsumed under mathematical principles. This singularly fruitful thought he exemplifies and illustrates by showing how geometry is applied to the action of natural bodies, and demonstrating by geometrical figures certain laws of physical forces. He also shows how his method may be used to determine some curious and long-discussed problems, such as the light of the stars, the ebb and flow of the tide, the motion of the balance. He then proceeds to adduce elaborate and sometimes slightly grotesque reasons tending to prove that mathematical knowledge is essential in theology, and closes this section of his work with two comprehensive sketches of geography and astronomy. That on geography is particularly good, and is interesting as having been read by Columbus, who lighted on it in Petrus de Alliaco's *Imago Mundi*, and was strongly influenced by its reasoning.

Part V. (pp. 256–357) treats of perspective. This was the part of his work on which Bacon most prided himself, and in it, we may add, he seems to owe most to the Arab writers Alkindi and Alhazen. The treatise opens with an able sketch of psychology, founded upon, but in some important respects varying from, Aristotle's *De Anima*. The anatomy of the eye is next described; this is done well and evidently at first hand, though the functions of the parts are not given with complete accuracy. Many other points of physiological optics are touched on, in general erroneously. Bacon then discusses very fully vision in a right line, the laws of reflection and refraction, and the construction of mirrors and lenses. In this part of the work, as in the preceding, his reasoning depends essentially upon his peculiar view of natural agents and their activities. His fundamental physical maxims are matter and force; the latter he calls *virtus*, *species*, *imago agentis*, and by numberless other names. Change, or any natural phenomenon, is produced by the impression of a virtus or species on matter—the result being the thing known. Physical action is, therefore, *impression*, or transmission of force in lines, and must accordingly be explained geometrically. This view of nature Bacon considered fundamental, and it lies, indeed, at the root of his whole philosophy. To the short notices of it given in the 4th and 5th parts of the *Opus Majus*, he subjoined two, or perhaps three, extended accounts of it. We possess at least one of these in the tract *De Multiplicatione Specierum*, printed as part of the *Opus Majus* by Jebb (pp. 358–444). We cannot do more than refer to Charles for discussions as to how this theory of nature is connected with the metaphysical problems of force and matter, with the logical doctrine of universals, and in general with Bacon's theory of knowledge.

Part VI. (pp. 445–477) treats of experimental science, "*domina omnium scientiarum.*" There are two methods of knowledge: the one by argument, the other by experience. Mere argument is never sufficient; it may decide a question, but gives no satisfaction or certainty to the mind, which can only be convinced by immediate inspection or intuition. Now this is what experience gives. But experience is of two sorts, external and internal; the first is that usually called experiment, but it can give no complete knowledge even of corporeal things, much less of spiritual. On the other hand, in inner experience the mind is illuminated by the divine truth, and of this supernatural enlightenment there are seven grades.

Experimental science, which in the *Opus Tertium* (p. 46) is distinguished from the speculative sciences and the operative arts in a way that forcibly reminds us of Francis Bacon, is said to have three great *prerogatives* over all other sciences:—(1.) It verifies their conclusions by direct experiment; (2.) It discovers truths which they could never reach; (3.) It investigates the secrets of nature, and opens to us a knowledge of past and future. As an instance of his method, Bacon gives an investigation into the nature and cause of the rainbow, which is really a very fine specimen of inductive research.

The seventh part of the *Opus Majus*, not given in Jebb's edition, is noticed at considerable length in the *Opus Tertium* (cap. xiv.) Extracts from it are given by Charles (pp. 339–348).

As has been seen, Bacon had no sooner finished this elaborate work than he began to prepare a summary to be sent along with it. Of this summary, or *Opus Minus*, part has come down and is published in Brewer's *Op. Ined.* (313–389), from what appears to be the only MS. The work was intended to contain an abstract of the *Opus Majus*, an account of the principal vices of theology, and treatises on speculative and practical alchemy. At the same time, or immediately after, Bacon began a third work as a preamble to the other two, giving their general scope and aim, but supplementing them in many points. The part of this work, generally called *Opus Tertium*, is printed by Brewer (pp. 1–310), who considers it to be a complete treatise. Charles, however, has given good grounds for supposing that it is merely a preface, and that the work went on to discuss grammar, logic (which Bacon thought of little service, as reasoning was innate), mathematics, general physics, metaphysics, and moral philosophy. He founds his argument mainly on passages in the *Communia Naturalium*, which indeed prove distinctly that it was sent to Clement, and cannot, therefore, form part of the *Compendium*, as Brewer seems to think. It must be confessed, however, that nothing can well be more confusing than the references in Bacon's works, and it seems well-nigh hopeless to attempt a complete arrangement of them until the texts have been collated and carefully printed.

All these large works Bacon appears to have looked on as preliminaries, introductions, leading to a great work which should embrace the principles of all the sciences. This great work, which is perhaps the frequently referred to *Liber Sex Scientiarum*, he began, and a few fragments still indicate its outline. First appears to have come the treatise now called *Compendium Studii Philosophiæ* (Brewer, pp. 393–519), containing an account of the causes of error, and then entering at length upon grammar. After that, apparently, logic was to be treated; then, possibly, mathematics and physics; then speculative alchemy and experimental science. It is, however, very difficult, in the present state of our knowledge of the MSS., to hazard even conjectures as to the contents and nature of this last and most comprehensive work.

Bacon's fame in popular estimation has always rested on his mechanical discoveries. Careful research has shown that very little in this department can with accuracy be ascribed to him. He certainly describes a method of constructing a telescope, but not so as to lead one to conclude that he was in possession of that instrument. Gunpowder, the invention of which has been claimed for him on the ground of a passage in his works, which fairly interpreted at once disposes of any such claim, was already known to the Arabs. Burning-glasses were in common use, and spectacles it does not appear he made, although he was probably acquainted with the principle of their construction. His wonderful predictions (in the *De Secretis*) must be taken *cum grano salis;* and it is not to be forgotten that he believed in astrology, in the doctrine of signatures, and in the philosopher's stone, and *knew* that the circle had been squared.

The best work on Roger Bacon is undoubtedly that of E. Charles, *Roger Bacon, sa Vie, ses Ouvrages, ses Doctrines d'après des textes inédits*, 1861. Against the somewhat enthusiastic estimate and modern interpretation given in this work, Schneider in his *Roger Bacon, Eine Monographie*, Augsburg, 1873, has reclaimed. He points out very clearly certain aspects in which Bacon appears as a mere scholastic. The new matter contained in the publications of Charles and Brewer was summarised by H. Siebert, *Roger Bacon: Inaugural Dissertation*, Marburg, 1861. *Cf.* also, J. K. Ingram, *On the Opus Majus of Bacon*, Dublin, 1858; Cousin, *Fragments, Phil. du Moyen Age* (reprinted from *Journal des Savans*, 1848); Saisset, *Précurseurs et Disciples de Descartes*, pp. 1–58 (reprinted from *Revue de Deux Mondes*, 1861); Prantl, *Gesch. der Logik*, iii. 120–129 (a severe criticism of Bacon's logical doctrines). (R. AD.)

BACONTHORPE, or BACON, JOHN, called The Resolute Doctor, a learned monk, born towards the end of the 13th century, at Baconthorpe, a village in Norfolk. After spending the early part of his life in the convent of Blakeney, near Walsingham, he removed to Oxford, and from that city to Paris, where he obtained great reputation for his learning, and was esteemed the principal of the Averroists. In 1329 he returned to England, and was chosen twelfth provincial of the English Carmelites. In 1333 he was sent for to Rome, where, we are told, he first maintained the Pope's sovereign authority in cases of divorce; but this opinion he is understood to have afterwards retracted. He died in London in 1346. His chief work was published in 1510, with the title *Doctoris resoluti Joannis Bacconis Anglici Carmelitæ radiantissimi opus super quattuor sententiarum libris*, 4 vols. folio; it has passed through several editions. The little that is known of this schoolman, who in his own day and order had a reputation rivalling that of Thomas Aquinas, may be seen in Brucker, *Hist. Crit.*, iii. 865; Stöckl, *Phil. d. Mittel.* ii. 1044–5; Hauréau, *Phil. Scol.*, ii. 476; Prantl, *Ges. d. Logik*, iii. 318.

BACSANYI, JANOS, a Hungarian poet, was born at Tapoleza, May 11, 1763, and died at Linz, May 12, 1845. In 1785 he published his first work, a patriotic poem, *The Valour of the Magyars*. In the same year he obtained a situation as clerk in the treasury at Kaschau, and there, in conjunction with other two Hungarian patriots, edited the *Magyar Museum*, which was suppressed by the Government in 1792. In the following year he was deprived of his clerkship; and in 1794, having taken part in the conspiracy of Bishop Martinovich, he was thrown into the state prison of the Spielberg, near Brünn, where he remained for two years. After his release he took a considerable share in the *Magyar Minerva*, a literary review, and then proceeded to Vienna, where he obtained a post in the bank, and married. In 1809 he translated Napoleon's proclamation to the Magyars, and, in consequence of this anti-Austrian act, had to take refuge in Paris. After the fall of Napoleon he was given up to the Austrians, who allowed him to reside at Linz, on condition of never leaving that town. He published a collection of poems at Pesth, 1827 (second edition, Buda, 1835), and also edited the poetical works of Anyos and Faludi.

BACTRIA, or BACTRIANA, an ancient country of Central Asia, lying to the south of the River Oxus, and reaching to the western part of the Paropamisan range, or Hindu Kush. It was sometimes regarded as including the district of Margiana, or Merv, which was more frequently considered as distinct. The character of the country is very various, and has been well described by Curtius, whose account is confirmed by the few modern travellers who have passed through it. Some portions are remarkable for the beauty of their scenery, or the fertility of the soil, evidenced by a rich and varied vegetation, while other parts are stretches of barren and drifting sands. In early history Bactria is connected with some of the most important movements of the Indo-European races, and has no small claims to be regarded as the cradle of our present civilisation. According to Persian tradition, it became the seat of the Iranian wanderers, who established the religion of Zoroaster, and expelled the Vedic inhabitants of the country. In the 7th century B.C. it passed under the dominion of the Medes, and not long after formed part of the conquests of Cyrus. In the reign of Darius it ranked as the twelfth satrapy of the empire, and furnished valuable contingents to the imperial army; these are described at a later date by Herodotus as wearing the Median head-dress, and making use of their native bows and short spears. Like the rest of Western Asia, Bactria was subjugated by Alexander, and formed part of the empire of the Seleucids; but in the 3d century B.C. it was raised to the rank of an independent kingdom by the successful revolt of Diodotus, the Greek satrap. There thus arose a remarkable dynasty—if dynasty it can be called—of Græco-Bactrian kings, who have been the object of much modern investigation, but are not as yet arranged in any satisfactory order. The names of seven or eight of them are known from the Greek and Roman historians, and upwards of forty are preserved on their coins. The great problem to be solved by numismatists is how to dispose of so many claimants in the comparatively narrow space of time at their disposal. It is highly probable that many of them held contemporaneous sway in different parts of the Bactrian region, sometimes with a distinct preponderance on the part of one, and sometimes with practical equilibrium of power; but their geographical distribution can only be conjectured from what are understood to be mint-marks on their coins. The period of the final disintegration of the Græco-Bactrian power is not definitely ascertained; but as early as the time of Eucratides (160 B.C.) there appears on the coinage the so-called Bactrian Pali, a language cognate with Sanskrit but written in characters of seemingly Phœnician origin. Besides these monetary legends, several Bactrian inscriptions have been recently discovered, among the most important of which are the "Taxila" copperplate, which has furnished the key to the Bactrian numeral system, the Peshawur vase, the Manikyala cylinder, the Bimaran vase, and the Wardak urn, but none of them are of very much historical value. Bactria seems to have passed successively under the power of various Saca and Parthian and so-called Indo-Scythian rulers, and during the first six or seven centuries of the Christian era it became one of the most important centres of Buddhistic monasticism. (See BALKH.) Its modern history is of but little importance, as it has never formed an independent kingdom of any power or stability.

BACUP, a town of England, in Lancashire, 20 miles N. from Manchester. It is situated in a beautiful valley on the River Speddon, and is a station on the East Lancashire railway. It is chiefly important for its factories, foundries, and mills, as well as for the coal-mines in the neighbourhood. Since 1841, when the population of the chapelry was only 1526, Bacup has rapidly increased, and its sanitary condition has been greatly improved by the exertions of a local board. The river has been deepened for a mile above the town, and a water supply has been secured by means of a reservoir at Higher Stacks. There are two Episcopal

churches and several dissenting places of worship, a mechanics' institute and library, and various other institutions. A new market-hall was built in 1867. Population of local board district in 1871, 17,199.

BADAJOS, a province of Spain, forming, by the division of 1833, the southern half of the old province of Estremadura, or what is generally called Lower Estremadura. It is bounded on the N. by Caceres, E. by Ciudad Real, S. and S.E. by Cordova, Seville, and Huelva, and W. by Portugal, embracing an area of 8687 square miles. See ESTREMADURA.

BADAJOS, the capital of the above province, is a fortified city, and the see of a bishop. It is situated about 5 miles from the Portuguese frontier, on a slight elevation near the left bank of the Guadiana, and is one of the principal stations on the railway between Madrid and Lisbon. The height is crowned by the ruins of a Moorish castle. A strong wall and bastions, with a broad moat and outworks, and forts on the surrounding heights, make the city a place of great strength. The river is crossed by a magnificent granite bridge, originally built in 1460, repaired in 1597, and rebuilt in 1833. The city is well built, and contains an arsenal, a cathedral, built like a fortress and bombproof, several churches, hospitals, and schools. Its monasteries are all secularised, one being occupied as infantry barracks; and some of its nunneries are closed. Badajos was finally taken from the Moors in 1235 by Alphonso IX., and from its importance as a frontier garrison has since been the scene of numerous sieges. The last and most severe was in 1812, when it was stormed by the British troops under Wellington and carried with dreadful loss. The town was delivered up to a two days' pillage. It had been surrendered the previous year to Soult by the treachery of Imaz, the commander of the garrison. The trade and manufactures of Badajos are considerable, and much contraband traffic is carried on with Portugal. Badajos is the birthplace of the painter Luis de Morales and of Manuel Godoy. Pop. 22,895.

BADAKHSHÁN, a country of Central Asia, situated in the upper valley of the Kokcha river, one of the principal head streams of the Oxus. The name has been variously spelt Badascian, Balacian, Balakhshan, Balashan, Balaxien and Balaxia. Including Wakhan, it lies between 35° 50′ and 38° N. lat., and between 69° 30′ and 74° 20′ E. long. The chief ascertained positions are as follows: Faizábád, 37° 2′ N., 70° 36′ E.; Ishkáshm, 36° 45′ N., 71° 38′ E.; Punja, 37° 5′ N., 72° 39′ E.; and Karkat Yassin lake, 37° 14′ N., 74° 18′ E. Its extent from east to west is about 200 miles, and from north to south about 150 miles. On the north it is bounded by Kulab and Darwaz; on the east by the lofty table-land of Pamir; on the south by the Hindu Kush range; and on the west by Kunduz. The Pamir land is the principal watershed of Asia, and Badakhshan forms part of the western water slope constituting the basin of the Oxus. The country is for the most part mountainous, but there are numerous plains and fertile valleys. The general slope of the country is great, since Kunduz is probably not more than 500 feet above the level of the sea, while Lake Victoria, close to the principal watershed, is estimated at 15,600 feet.

Badakhshan comprises 16 districts. The principal district called Faizábád is under the rule of the Mír Mahmúd Shah; the others are dependencies ruled by relatives of the Mír, or by hereditary feudatories. Each ruler is independent, but is bound to aid the Mír of Faizábád in time of need. The Mír himself pays tribute to the Amir of Cabul. The other districts besides Faizábád are Daraim, Shahr-í-buzurq, Gumbuz, Farakhar, Kishm, Rustak, Rushán, Shighnán, Ishkáshm, Wakhán, Zebak, Minján, Ragh, Daung, and Asiábá. Each district has its sub-divisions. In Faizábád there are several fertile tracts; amongst them are the hilly regions of Yaftal and Shewá, which are thickly populated, the former by Tajiks, and the latter by Turks of the Jakha Moghal tribe; and the plateaus of Argú and Shewá, of which the former is somewhat higher than the plain of Faizábád, about 15 miles in length by about 8 in breadth, and well cultivated, while the latter is still higher, and forms the best and largest pasture ground in Badakhshan. A lake named Sir-í-kol, about 20 miles in circumference, is situated on the Shewá plateau. In and around Faizábád there are numerous excellent fruit and flower gardens; the principal manufactures are cast-iron pots, boots and shoes, and a material woven from silk and cotton, called *ilacha*. The district of Jirm, also subject to Mahmúd Shah, comprises numerous rich valleys, as well as the famous mineral region called Yamgan, or "all mines." The mines yield rubies, lapis lazuli, lead, alum, sal-ammoniac, sulphur, copper, &c. The annual yield of lapis lazuli averages about £1500, which is sold at the rate of seven shillings per pound; it is exported to Russia, Kashmir, and China. The Dasht-Baha-rak is an extensive plain in this district, on which was formerly situated a large city, once the capital of Badakhshan. There are several villages on it, as also the summer residence of the Mír. The caravan route from India to Faizábád passes over this plain. The districts of Rustak, Ragh, Kishm, Daraim, and Shahr-í-buzurq are next in importance as regards fertility and population. They abound in fertile hills and plains. The principal cultivated products are wheat, rice, *Cicer arietinum*, *Phaseolus Mungo*, cotton, linseed, poppy, sesame, apples, grapes, mulberries (which form the principal article of food in these regions), pears, apricots, walnuts, melons, gourds, turnips, radishes, carrots, spinach, leeks, as also numerous garden flowers and timber trees. The districts of Minjan and Rushan are more mountainous, have a cooler climate, and are more sparsely populated than the foregoing. Their inhabitants are also distinct, differing in physical features, creed, language, and habits. The celebrated ruby mines are in Ishkáshm; they have not been worked for more than 30 years, except temporarily in 1866. It is, however, suspected that they are worked surreptitiously by the people. They yield the well-known Balas (*i.e.*, Badakhshan) ruby.

The principal domesticated animal is the yak. There are also large flocks of sheep, cows, goats, ponies, numerous fine dogs, and Bactrian camels. The more important wild animals are a large wild sheep (*Ovis poli*), foxes, wolves, jackals, bears, boars, deer, and lions; amongst birds, there are partridges, pheasants, ravens, jays, sparrows, larks, a famous breed of hawks, &c.

Badakhshan proper is peopled by Tajiks, Turks, and Arabs, who speak the Persian and Turki languages, and profess the orthodox doctrines of the Mahometan law adopted by the Sunnite sect; while the mountainous districts are inhabited by Tajiks, professing the Shia creed, and speaking distinct dialects in different districts.

Badakhshan was visited by Hwen Thsang in 630 and 644. The Arabian geographers of the 10th century speak of its mines of ruby and azure, and give notices of the flourishing commerce and large towns of Waksh and Khotl, regions which appear either to have in part corresponded with or to have lain close to Badakhshan. In 1272–73 Marco Polo and his companions stayed for a time in Badakhshan. During this and the following centuries the country was governed by kings who claimed to be descendants of Alexander the Great. The last of these kings was Shah Mahomet, who died in the middle of the 15th century, leaving only his married daughters to represent the royal line. Early in the middle of the 16th century the Uzbeks obtained possession of Badakhshan, but were soon expelled, and then the country was generally governed by descendants of the old royal dynasty by the female line. About the middle of the 18th century the present dynasty of

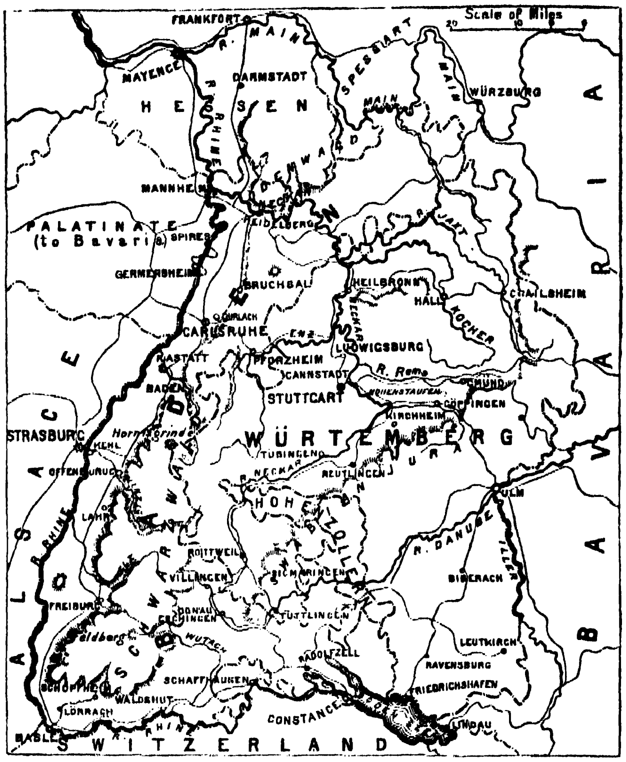
Mîrs established its footing in place of the old one which had become extinct. In 1765 the country was invaded and ravaged by the ruler of Cabul. During the first three decades of the present century it was overrun and depopulated by Kokan Beg and his son Murad Beg, chiefs of the Kataghan Uzbeks of Kundus. The country was still suffering from these disasters when Wood visited it in 1837. When Murad Beg died, the power passed into the hands of another Uzbek, Mahomet Amir Khan. In 1859 the Kataghan Uzbeks were expelled; and Mîr Jahander Shah, the representative of the modern royal line, was reinstated at Faizábád under the supremacy of the Afghans. In 1867 he was expelled by the Afghans and replaced by the present ruler, Mîr Mahomet Shah, and other representatives of the same family. According to the latest accounts the country was reviving from its past misfortunes, and the towns were again rising. Badakhshan owes part of its prosperity to the baneful traffic in slaves. A strong man is considered a fair exchange for a large dog or horse, and a fine girl for about four horses. The district is of some political interest in connection with the frontier line of Afghanistan, which has recently been the subject of discussion between the Russian and British Governments.

In 1867 a report on Badakhshan was drawn up by the Pundit Mun-phool after a sojourn of two or three years in the country. For further information, see the *Book of Ser Marco Polo*, vol. i. 1871, edited by Col. Yule; *A Journey to the Source of the River Oxus*, by Capt. J. Wood, edition of 1872; "Report on the Mirza's Exploration from Cabul to Kashgar," by Major Montgomerie, in the *Journal of Roy. Geo. Soc.*, vol. xli. p. 132; "A Havildar's journey through Chitral to Faizábád in 1870," by Major Montgomerie, in journal last mentioned, vol. xlii. p. 180; "Papers connected with the Upper Oxus Regions," by Col. Yule, in the same volume, p. 438; "Monograph on the Oxus," by Maj.-Gen. Sir H. C. Rawlinson, in the same volume, p. 482; and a paper by the writer last mentioned, "On Badakhshan and Wakhán," in the *Proceedings of the Roy. Geog. Soc.*, vol. xvii. p. 108.

BADALOCCHIO, Sisto, surnamed Rosa, a painter and engraver, was born at Parma in 1581, and died in 1641 or 1647. He was of the school of Annibale Carracci, by whom he was highly esteemed for design. His principal engravings are the series known as *The Bible* of Raffaelle, which were executed by him in conjunction with Lanfranc, another pupil of Carracci's. The best of his paintings, which are few in number, are at Parma.

BADEN, The Grand Duchy of, is situated in the S.W. of Germany, between 47° 32′ and 49° 52′ N. lat., and between 7° 27′ and 9° 50′ E. long. It is bounded on the N. by Bavaria and Hesse-Darmstadt; W. by Rhenish Bavaria, Alsace, and Lorraine; S. by Switzerland; and E. by Würtemberg and part of Bavaria. At the commencement of the present century Baden was only a margraviate, with an area little exceeding 1300 square miles, and a population of 210,000. Since then it has from time to time acquired additional territory, so that its area now amounts to upwards of 5800 square miles, and its population to nearly a million and a half.

It consists of a considerable portion of the eastern half of the fertile valley of the Rhine, and of the mountains which form its boundary. The mountainous part is by far the most extensive, forming, indeed, nearly 80 per cent. of the whole area. From the Lake of Constance in the south to the River Neckar is a portion of the so-called Black Forest or *Schwarzwald*, which is divided by the valley of the Kinzig into two districts of different elevation. To the south of the Kinzig the mean height is 3100 feet, and the loftiest summit, the Feldberg, reaches about 4780 feet; while to the north the mean height is only 2100 feet, and the Belchen, the culminating point of the whole, does not exceed 4480. To the north of the Neckar is the Odenwald range, with a mean of 1440 feet, and, in the Katzenbuckel, an extreme of 1980. Lying between the Rhine and the Dreisam is the Kaiserstuhl, an independent volcanic group, nearly 10 miles in length and 5 in breadth, the highest point of which is 1760 feet.



Sketch Map of the Grand Duchy of Baden.

The greater part of Baden belongs to the basin of the Rhine, which receives upwards of twenty tributaries from the highlands of the duchy alone; a portion of the territory is also watered by the Main and the Neckar. A part, however, of the eastern slope of the Black Forest belongs to the basin of the Danube, which there takes its rise in a number of mountain streams. Among the numerous lakes which belong to the duchy are the Mummel, Wilder, Nonnenmattweiher, Titti, Eichener, Schluch, &c., but none of them are of any size. The Lake of Constance, or Boden See, belongs partly to Bavaria and Switzerland.

From 1819 to 1832 Baden was divided into six circles, which were reduced in the latter year to the four following:—The Lake Circle or Constance, the Upper Rhine or Freiburg, the Middle Rhine or Carlsruhe, and the Lower Rhine or Manheim. This division, though still employed, has been legally supplanted by one into the eleven circles of Constance, Villingen, Waldshut, Freiburg, Lörrach, Offenburg, Baden, Carslruhe, Manheim, Heidelberg, and Mosbach. The capital of the duchy is Carlsruhe, which in 1871 had a population of 36,582; the other principal towns are Manheim (39,614), Freiburg (24,599), Heidelberg (19,988), Pforzheim (19,801), Rastadt (11,559), Baden (10,083), Constance (10,052), Bruchsal (9786), and Lahr (6710). The population is most thickly clustered in the north and in the neighbourhood of the Swiss town of Basel.

The mineral wealth of Baden is not very great; but the mines of Oberwert, Kandern, &c., produce excellent iron; there are two zinc mines and one of lead; coal is worked at Diesburg, Zunsweier, Baden, &c.; and silver, copper, gold, cobalt, alum, vitriol, and sulphur are also obtained in small quantities. Gold washing, at one time extensively carried on along the Rhine, is now little practised. Peat is found in abundance, as well as gypsum, china-clay, and

potter's earth. The duchy was formerly dependent on France for its salt supply, but extensive salt works have for a number of years been maintained by the Government at Dürrheim and Rappenau. In 1874 the amount produced was of the value of £54,880. The mineral springs of Baden are very numerous, and have acquired great celebrity,—those of Baden-Baden, Badenweiler, Antogast, Griesbach, Friersbach, and Petersthal, being the most frequented.

The inhabitants of Baden are of various origin,—those to the N. of the Murg being descended from the Alemanni, and those to the S. from the Franks, while the Swabian plateau derives its name and its population from another race. This distinction is still marked in the manners, the language, and the dress of the different districts. The majority of the people are engaged in agricultural and pastoral pursuits, for which much of the country is well adapted. In the valleys the soil is particularly fertile, yielding luxuriant crops of wheat, maize, barley, spelt, beans, potatoes, flax, hemp, hops, beet-root, and tobacco; and even in the more mountainous parts rye, wheat, and oats are extensively cultivated. There is a considerable extent of pasture land, and the rearing of cattle, sheep, pigs, and goats is largely attended to. The culture of the vine has recently been increasing, and the wines, which are characterised by a mildness of flavour, are in good demand. The gardens and orchards supply abundance of fruits, especially almonds and walnuts; and the keeping of bees is common throughout the country. A greater proportion of Baden than of any other of the South German states is occupied by forests. In these the predominant species are the fir and pine, but many others, such as the chestnut, are well represented. A third, at least, of the annual supply of timber is exported, the chief consumer being Holland, though of late years Paris has derived a considerable supply from this source.

The manufactures of Baden were formerly very insignificant, but have greatly increased since its accession to the Zollverein in 1835. They are, however, chiefly confined to iron and hardware goods, and the spinning and weaving of cotton. The latter industry is principally carried on at Ettlingen, Offenburg, St Blaise, Zell, Schopfheim; Manheim has an extensive manufacture of mirrors, and Carlsruhe of machines; while Pforzheim is famous for its production of jewellery and goldsmiths' work. Beet-root sugar is manufactured at Waghäusel more largely than anywhere else in Germany. Paper, leather, and tobacco are also important objects of industry. The inhabitants of the Black Forest have long been celebrated for their dexterity in the manufacture of wooden ornaments and toys, watches, clocks, musical boxes, organs, &c. Of clocks alone about 600,000 are made every year.

The exports of Baden, which coincide largely with the industries just mentioned, are of considerable importance, but the bulk of its trade consists in the transit of goods. The country is well furnished with roads and railways, the greater proportion of the latter being in the hands of the state. A line runs the whole length of the land, for the most part parallel with the Rhine, while branches cross obliquely from east to west.

The educational institutions of Baden are numerous and flourishing, and public instruction is largely subsidised by the Government. There are two universities, the Protestant one at Heidelberg, founded in 1386, and the Catholic one at Freiburg, founded in 1457. The library at Heidelberg numbers 150,000 volumes, and that at Freiburg 100,000, while there is another of almost equal size at Carlsruhe. There are also lyceums at Carlsruhe, Constance, Freiburg, Heidelberg, Manheim, Rastadt, and Wertheim; several gymnasiums; normal schools at Carlsruhe, Ettlingen, and Meersburg, besides upwards of 2000 common schools established throughout the country. There is an institution in Pforzheim for the deaf and dumb, and one in Freiburg for the blind. The polytechnic school at Carlsruhe is among the most efficient institutions of the kind in Germany. The preparatory course extends over three years, and includes French, German, English, special history, mathematics, drawing, modelling, chemistry, mineralogy and geology, mechanics, &c. The special courses are engineering, architecture, forestry, chemistry, mechanics, commerce, and post-office service, and extend over from one to four years. The ducal family of Baden belong to the Protestant section of the Church, but the majority of the population are Roman Catholics. The returns of the census of 1871 are as follows:—Catholics, 942,560; Protestants, 491,008; other sects, 2265; and Jews, 25,703. The district where the Roman Catholic preponderance was greatest was Constance, while the Protestants were slightly more numerous in the district of Manheim.

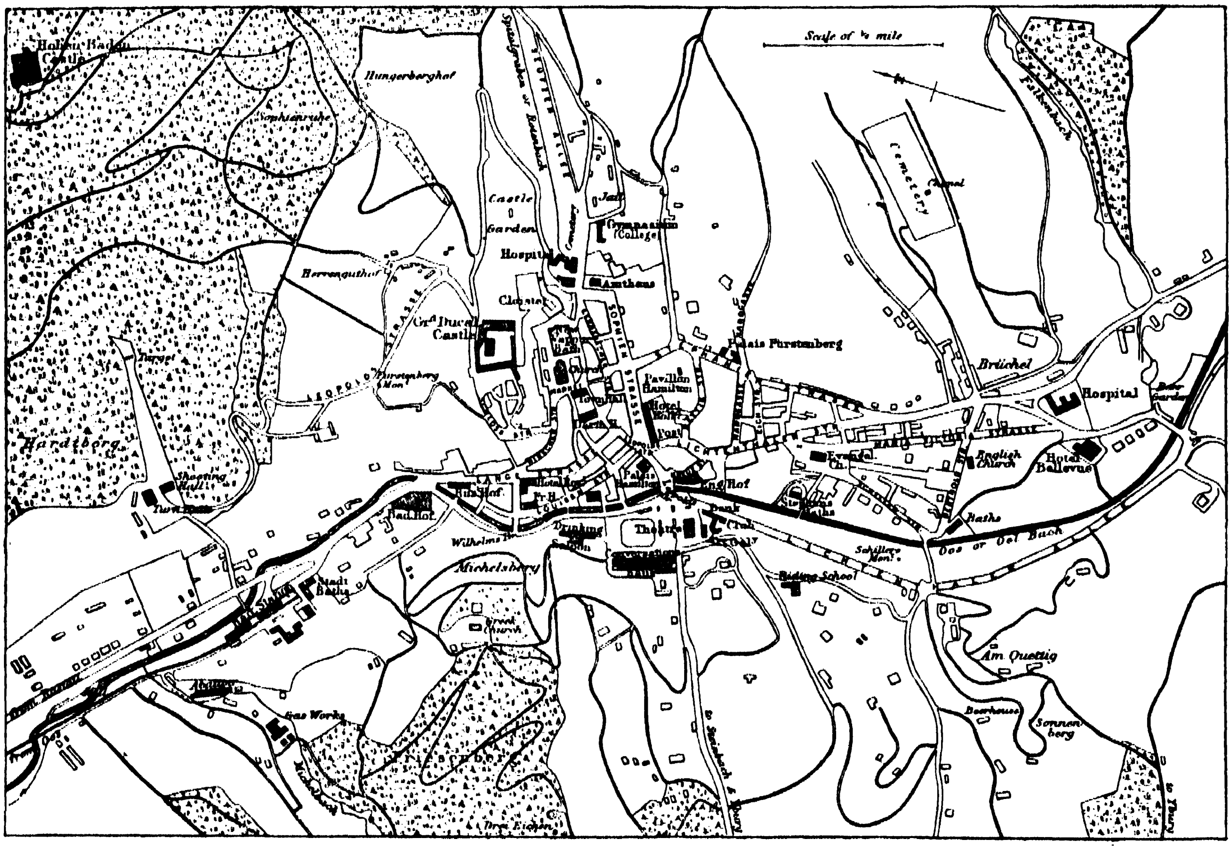
The government of Baden is an hereditary monarchy, with the executive power vested in the grand duke, and the legislative authority in a Parliament consisting of two Chambers. The upper Chamber is composed of all the princes of the reigning line who are of age, the chiefs of ten noble families, the possessors of hereditary landed estates worth £25,000, the Roman Catholic archbishop of Freiburg, the president of the Protestant Church, a deputy from each of the universities, and eight nominees of the duke. The lower Chamber consists of 63 representatives, of whom 22 are elected by the burgesses of certain towns, and 41 by the inhabitants of the bailiwicks. The parliamentary candidate must possess tax-paying property of the value of 10,000 florins (£833), or derive a salary of at least £125 from a public office. Every citizen, if neither criminal nor pauper, has the right of voting, but only in the choice of deputy-electors, by whom the real election of the representatives is decided. The members of the lower House are elected for eight years, and meetings of Parliament must take place every two years.

The budgets are granted by Parliament for a term of two years. In 1875 the ordinary expenses were rated at £1,572,959, and the ordinary receipts at £1,557,108. The total public debt on the 1st of January 1874 was £12,985,067.

Since the organisation of 1864 courts are held at Constance, Freiburg, Offenburg, Carlsruhe, and Manheim, the supreme court being in the city last named. Manheim is also the seat of the central commission for the navigation of the Rhine.

The ducal family of Baden traces its descent from the counts of Zähringen, who flourished in the 11th century, and derived their title from what is now a little town to the north of Freiburg. Hermann I., the second son of Count Berthold I., took the title of margrave of Hochberg in Breisgau, and was succeeded in 1074 by his son Hermann II., who was the first to style himself margrave of Baden. On the death of the Margrave Christopher in 1527, his estates were divided among his three sons, but one of them having died soon after, the two survivors became the sole inheritors, and founded the two lines of Baden-Baden and Baden-Durlach. The former of these, which produced one of the most famous generals of the 17th century, became extinct by the death of Augustus George in 1771, and its possessions were united with Baden-Durlach under Charles Frederick. By the treaty of Lunéville in 1801, Baden acquired a considerable addition of territory; in 1803 the margrave received the title of Elector; and by the treaty of Presburg in 1805 his domains were still further increased by the accession of Breisgau. On the dissolution of the empire in 1806, the elector

joined the Confederation of the Rhine, and received the title of Grand Duke, with 1950 square miles of additional territory. Shortly after this extension and consolidation had taken place, Bavaria laid claim to a portion of the duchy, but her demands were indignantly rejected, and in 1818 the grand duke bestowed on the country a political constitution, the fundamental principle of which was the territorial integrity of Baden. In the following year this integrity was guaranteed by the Frankfort Commission. The first session of the Baden parliament fell into disputes and had to be dissolved; but the second, in 1820, commenced the work of reform by the complete abolition of serfdom and the establishment of ministerial responsibility. In 1821 the union of the two Protestant churches in Baden was brought about. Other questions of importance, such as trial by jury, freedom of the press, abolition of tithes, and extension of education, became subjects of interest and debate; but, unfortunately, the influence of the French revolution of 1830 led the democratic party to excesses, which the Government met with acts of ill-advised repression. Matters were beginning to readjust themselves when the revolution of 1848 again aroused the opposing forces. In 1849 the duke was constrained to flee, and Brentano, the democratic leader, took possession of Carlsruhe in the name of the national committee. By the 25th of June, however, the Prussian forces, after several severe engagements with the revolutionists, effected the restoration of the duke, who returned to his capital on 18th August; and it was not long before the country began to recover from the effects of the outbreak. Not, indeed, that it became quiescent; for Baden has had its full share in the political and ecclesiastical disputes that have been so rife throughout Germany during recent years. The Roman Catholic clergy, with the bishop of Freiburg at their head, have maintained an obstinate struggle with the Liberal party, which is now predominant. The separation of church and state has been established; the Jews have been admitted to full civic rights; freedom of trade has been promulgated, and a number of minor reforms successfully carried through. In the German war of 1866 Baden sided against Prussia; but in 1870 it joined in the formation of the new German empire, and its troops are incorporated in the 14th corps of the imperial army.



Ground-Plan of Baden-Baden.

BADEN (or Baden-Baden, to distinguish it from other places of the name), a town and celebrated watering-place of Germany, in the grand duchy of Baden. It stands on the side of a hill, near the Oos or Oel, in a beautiful valley of the Black Forest, 18 miles S.W. of Carlsruhe; and it is connected by a branch with the Manheim and Basel railway. The superiority of its situation, its extensive pleasure-grounds, gardens, and promenades, and the brilliancy of the life that is led during the season, have for a long series of years continued to attract crowds of visitors from all parts of the world. The resident population amounts to about 10,000, but that number is frequently augumented fourfold. The prevailing nationality is, or rather was, the French, but Americans, Russians, and English are all numerously represented. The hot springs, which were among the earliest attraction of the place, are twenty-nine in number, and vary in temperature from 37° to 54° R., *i.e.*, from 115° to 153° Fahr. They flow from the castle rock at the rate of 90 gallons per minute, and the water is conveyed through the town in pipes to supply the different baths. The town proper is on the right bank of the Oos, but the principal resorts of the adventitious population are on the other side. A *Conversationshaus* and a *Trinkhalle* or pump-room (1842), a theatre (1861), and a picture-gallery, are among the chief fashionable buildings, to which may be added the library and reading-room. The gaming-tables, which for so many

years were a striking feature of Baden-Baden, are now abolished. The only building of much antiquarian interest, with the exception of the castles, is the parish church, which dates from the 15th century, and contains the tombs of several of the margraves. There is a Protestant church a short distance to the east of Leopoldsplatz, and not far off a small Episcopalian church; while on the Michaelsberg is the Greek chapel, with its gilded dome, which was erected over the tomb of the Roumanian prince, Michael Stroudza, who died at Baden in 1863.

The springs of Baden were known to the Romans, and the foundation of the town is referred to the Emperor Hadrian by an inscription of somewhat doubtful authenticity. The name of *Aurelia Aquensis* was given to it in honour of Aurelius Severus, in whose reign it would seem to have been well known. Fragments of its ancient sculptures are still to be seen, and in 1847 remains of Roman vapour baths, well preserved, were discovered just below the New Castle. From the 14th century down to the close of the 17th, Baden was the residence of the margraves, to whom it gave its name. They first dwelt in the Old Castle, the ruins of which still occupy the summit of a hill above the town, but in 1479 they removed to the New Castle (still so called), which is situated on the hill-side nearer to the town, and is remarkable for its subterranean dungeons. During the Thirty Years' War Baden suffered severely from the various combatants, but especially from the French, who pillaged it in 1643, and laid it in ashes in 1688. The margravine Sibylla rebuilt the New Castle in 1697, but the margrave Louis removed to Rastadt in 1706. Since the beginning of the present century the Government has greatly fostered the growth of the town.

BADEN, Switzerland, a small town in the canton of Aargau, on the Limmat, 14 miles N.W. of Zurich. It is much frequented on account of its warm medicinal springs, which are about 20 in number, and vary in temperature from 98° to 126° Fahr. About 15,000 persons visit the place annually. Tacitus, in the first book of his *Histories* (c. 67), incidentally speaks of it as *in modum municipii extructus locus, amœno salubrium aquarum usu frequens;* and numerous remains of pillars and inscriptions, coins, and other antiquities confirm his description. It was destroyed by the Alemanni and the Huns, but was again frequented during the reign of Charlemagne, though its modern prosperity only dates from the 15th century. For a long time the countship of Baden was in the hands of the Hapsburgs, but it was conquered by the Swiss Confederates in 1415. It was here that the famous disputation of Eck with Zwingle and Œcolampadius took place in 1526; and here was held the conference of 1589. In 1714 the peace which put an end to the war of the Spanish Succession was concluded at Baden between Austria and France; and four years afterwards a treaty between Zurich, Berne, and St Gall received its name from the town. Resident population, 3412.

BADEN, the chief town of a circle in Lower Austria, about 12 miles S. of Vienna on the railway to Gratz. It is beautifully situated at the mouth of the romantic *Helenenthal*, near the banks of the Schwachat, a rapid stream with several waterfalls, and has become a favourite summer resort with the inhabitants of the neighbouring capital. The warm baths, which give name to the town, are thirteen in number, and vary in temperature from 72° to 97° Fahr. They rise, for the most part, at the foot of the *Calvarienberg*, which is composed of dolomitic limestone. The number of patients is about 8000 annually. The celebrity of Baden dates back to the days of the Romans, who knew it by the name of *Aquæ Cetiæ;* and remains of their occupation still exist. In 1812 the town suffered severely from a fire, but it has since been elegantly rebuilt. The principal buildings are the church of St Stephen, the theatre, the casino, and the military hospital. A short distance to the west of the town stands the castle of Weilberg, which belongs to members of the imperial family. The only manufacture of much importance that is carried on in Baden is the production of steel-wares; these, especially the razors, are of excellent quality. Permanent population, about 6500.

BADGER (*Meles*), a family of Plantigrade Carnivora, possessing greatly elongated bodies and short limbs, each of the latter furnished with five toes, provided at their extremities with long, powerful claws, by means of which they form deep burrows in the earth. The carnassial tooth, which in the bears is wholly tuberculate, is in the badgers provided also with a cutting edge, their whole dentition being specially adapted to the partly vegetable, partly animal diet on which they subsist. The badger differs from all other mammals in having the lower jaw so articulated to the upper, by means of a transverse condyle firmly locked into a long cavity of the cranium, that dislocation of the jaw is all but impossible, and this enables those creatures to maintain their hold with the utmost tenacity. The European badger (*Meles Taxus*) may be taken as typical of the entire family. It is nowhere abundant, but is found over the entire northern parts of Europe and Asia. It is a quiet, inoffensive animal, nocturnal and solitary in its habits, sleeping by day in its burrow, and issuing forth at night to feed on roots, beech-mast, fruits, the eggs of birds, some of the smaller quadrupeds, frogs, and insects. It is said also to dig up the nests of wasps in order to eat the larvæ, as the ratel—a closely allied South African form—is said to rob the bees of their honey. The male and female are seldom seen together, and are supposed to trace each other by means of the odour of the secretion contained in a glandular pouch beneath the tail. Although the badger does not seek to attack, yet, when driven to bay, its great muscular power and tough hide render it a formidable antagonist, as was often seen in the days, now happily gone by, when badger-baiting was a favourite amusement of the English peasantry. Fossil remains of the badger have been found in this country, apparently contemporaneous with the extinct cave bear, hyena, and tiger; still more ancient remains are said to have been found in the Red Crag of Suffolk, and should these prove authentic, the European badger, says Professor Owen, "will be the oldest known species of mammal now living on the face of the earth." The American badger (*Meles Labradorica*) is a native of California and Texas, and in its habits closely resembles the former species; it seems, however, to be more carnivorous. According to Gray, several species inhabit the southern parts of Asia. When badgers were more abundant than they now are, their skins dressed, with the hair attached, were commonly used for pistol furniture. They are now chiefly valued for the hair, that of the European badger being used in the manufacture of the best shaving-brushes, while the softer hair of the American species is employed for the same purpose, and also for painters' pencils. 5197 skins of the American badger were imported into London during 1873.

BADIA Y LEBLICH, DOMINGO, a celebrated Spanish traveller, better known under his assumed name of Ali Bey, was born in Biscay in the year 1766. After receiving a liberal education he devoted particular attention to the Arabic language, and made special preparation otherwise for his Oriental travels. Under the name of Ali Bey and in Mussulman costume, he visited Egypt, Marocco, Tripoli, Arabia, and Syria, and was received as a person of high rank wherever he appeared. On his return to Europe in 1807 he declared himself a Bonapartist, and was made Intendant, first of Segovia, and afterwards of Cordova. When the French were driven from Spain, Badia was compelled to take refuge in France, and there, in 1814, published an

account of his travels under the title of *Voyage d'Ali Bey en Asie et en Afrique, &c.*, in 3 vols. 8vo. A few years later he set out again for Syria, under the assumed name of Ali Othman, and, it is said, accredited as a political agent by the French Government. He only reached Aleppo, and there died, 30th August 1818, not without suspicion of having been poisoned.

BADIUS, Jodocus or Josse, sometimes called Badius Ascensius from the village of Asche, near Brussels, where he was born in 1462, was an eminent printer at Paris, whose establishment was celebrated under the name of *Prelum Ascensianum*. He was himself a scholar of considerable repute, had studied at Brussels and Ferrara, and before settling in Paris, had taught Greek for several years at Lyons. He illustrated with notes several of the classics which he printed, and was the author of numerous pieces, amongst which are a life of Thomas à Kempis, and a satire on the follies of women, entitled *Navicula Stultarum Mulierum*. He died in 1535. His epitaph was written by his grandson, the celebrated Henry Stephanus.

BADMINTON, a game of recent introduction. It may be played in or out of doors, by any number of persons from two to eight; two or four makes the best game. The

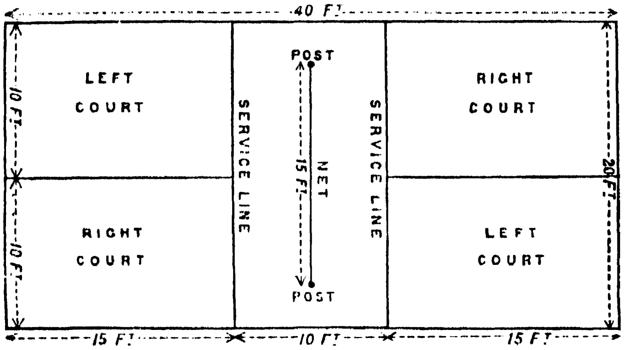


Diagram illustrating the Game of Badminton.

following description applies to the outdoor game; the indoor follows the same plan, modified only by circumstances affecting a room.

A tolerably level surface is required to form a *ground*. Turf or asphalt is the best. The size of the ground varies from 40 ft. by 20 ft. to 30 ft. by 15 ft., according to the space at command and the activity of the players.

The ground is divided into *courts* as shown in the diagram, which gives the marking-out and measurements of a full-sized ground.

The *boundaries* of the ground and of the courts should be defined by means of whiting and water, or pegged-down tape, the former being preferable.

On each of the spots marked "post," half-way between the service lines, and 15 ft. apart, a *post* about 6 ft. high must be erected, either on a stand or driven into the ground, and supported by guy-ropes.

A *net*, about 5 ft. 6 in. or 5 ft. high, should be stretched from post to post. The depth of the net is of but little consequence. Where expense is no object, it should reach to the ground.

The implements required in playing the game are—(1), *shuttlecocks*, and (2), *rackets* or *battledores*. The former should be about 5 in. high, and about 1 oz. in weight. For outdoor play the shuttlecocks are sometimes made heavier by being loaded with lead. The body should be covered with india-rubber. The rackets should be similar to those used at the game of the same name, only smaller, about 2 ft. 6 in. long.

The game consists in sending the shuttlecock with the racket over the net, forwards and backwards, until one of the players fails to return it. The players decide by lot which shall commence or have first *hand-in* and choice of ends. The player who is hand-in (say A) stations himself in one of the courts at his end, his adversary (say B) in the diagonally opposed court at the other end. A. then *serves* to B., *i.e.*, A. standing in the court chosen by him, strikes the shuttlecock over the net with the racket into the diagonally opposed court. B. then has to *return the service* by striking the shuttlecock back over the net without allowing it to touch the ground, and so on alternately until one player fails. If this is the player who served, he is hand-out, his adversary becomes hand-in, and serves, and no score accrues. But if the player failing is the one who was served to, his adversary scores one point towards game, called an *ace*. The player who first scores 15 aces wins the game; but if the score arrives at 14 all, it is necessary for one player to score two consecutive aces in order to win.

The server must serve according to the following conditions:—He must stand with both feet in the court served from; he must send the shuttlecock clean over the net (*i.e.*, without touching net or posts), and so that it will drop into or beyond the service line bounding the court served into, and into the diagonally opposed court. If he fails to comply with these conditions it is a *fault*, and he has to serve again. Two consecutive faults put his hand out.

The server's hand is also out if he fails to send the shuttlecock over the net; if he hits the shuttlecock beyond the external boundary of the ground, or more than once; or, if after the server has loosed it, it touches him. No fault is allowed for these failures, as they are considered more serious than those first enumerated. After service is properly given, if either player fails to return the shuttlecock clean over the net, and so that it drops within the external boundary of the ground on the side of the net furthest from the striker, the player failing loses an ace, or is hand-out as the case may be. It will be observed that in the service the shuttlecock must be sent from right court to right court, or from left to left, but in the return, by either player, it is only required that the shuttlecock shall drop within any part of the ground, bounded by the external line of all. In addition the shuttlecock must be struck before it touches the ground, and must be touched only with the racket, and must only be hit once, otherwise it counts against the striker. If the shuttlecock drops on the line enclosing the court served into, or in the return drops on the boundary line, it is generally reckoned as a *let*, *i.e.*, the stroke or innings goes for nothing, and the server serves again. But this is an utterly useless rule, and it is better to count everything that drops on the line to the striker.

In the case of a fault, or in the case of returns that are not according to the conditions, if the adversary returns or attempts to return the shuttlecock, the service or return counts the same as though it had been properly made. If the server scores he serves again, this time from his other court, and so on alternately from one court to the other as long as he scores. When he is hand-out, his adversary commences serving from either of the courts at his end, and, on scoring, serves from his other court, and so on. In partner games the disposition of the players, and the rules by which they conduct the game, as to the two hands in, and so forth, are identical with those which prevail at lawn tennis. See Tennis. (H. J.)

BADNUR, the headquarters of the district of Betúl, consists, besides the European houses, of two bázárs. The largest, the Kothi Bázár, has a population of 2015 souls. The public buildings are the Commissioner's court-house, the district court-house, the jail, the schools, the police-station, the post-office, the dispensary, &c. There is a good *sarái* or inn for native travellers, and a *dák bangalow* or resting-place for Europeans. Not far from Badnúr is Kherlá, the former residence of the Gond Rájás, where

there is an old fort, now in ruins, which used to be held by them. Lat. 21° 57′ N., long. 77° 59″ E.

BADRINATH, a town and celebrated temple in Hindustán, in the British district of Garhwal, situate on the right bank of the Vishnugangá, a tributary of the Alaknandá River, in the middle of a valley nearly 4 miles in length, and 1 in breadth, in 30° 44′ N. lat. and 79° 32′ E. long. The town is small, containing only twenty or thirty huts, in which reside the Bráhmans and the attendants on the temple. The building, however, which is considered a place of high sanctity, by no means corresponds to its great celebrity. It is about 40 or 50 feet in height, built in the form of a cone, with a small cupola, on the top of which is a gilt ball and spire, and contains the shrine of Badrináth, dedicated to an incarnation of Vishnu. The principal idol is of black stone, and is 3 feet in height. Badrináth is the favourite resort of pilgrims from all parts of India. In ordinary years the number varies from 7000 to 10,000; but every twelfth year, when the festival of Kumbh Melá is celebrated, the concourse of persons is said to be 50,000. In addition to the gifts of votaries, the temple enjoys a further source of revenue from the rents of villages assigned by former Rájás. Some years ago the temple was shattered by an earthquake, and has only been partially restored. It is situate among mountains rising 23,000 feet above the level of the sea. Elevation of the site of the temple, 10,294 feet.

BAENA, a town of Spain, in the province of Cordova, 8 leagues S.E. of the city. It is picturesquely situated, near the River Marbello, on the slope of a hill crowned with a castle, which formerly belonged to Gonzalo de Cordova, and is now the property of the Altamira family. It has four parish churches and three schools, one of which, exclusively for girls, has a high reputation in the province. The education, which is conducted by sisters of charity, does not go beyond reading, writing, arithmetic, and religious instruction. Grain and oil are the principal articles of commerce. The site of the Roman town (*Baniana* or *Biniana*) can still be traced, and various antiquities are frequently met with. A subterranean vault was discovered in 1833, containing twelve cinerary urns, with inscriptions commemorating various members of the Pompeian family. In 1292 Mahomet Ibn Aljama vainly besieged the city, the defence of which on that occasion is commemorated by the five Moorish heads in its coat-of-arms. Baena is the birthplace of Juan de Peñalosa. Population, about 12,000.

BAEZA (ancient *Beatia*), a city of Spain, in the province of Jaen. It stands on a considerable elevation, about 3 miles from the right bank of the Guadalquivir. Lat. 37° 59′ N., long. 3° 28′ W. It is well built, and has a cathedral and several fine public buildings, among which the most worthy of notice are the university (founded in 1533, and for some time defunct), the oratorio of the order of St Philip Neri, and the marble fountain with Caryatides in the Plaza de la Constitucion. The Cordova and Ubeda gates, and the arch of Baeza, are among the remains of its old fortifications, which were of great strength. There is little trade or manufacture here. The principal productions of the neighbourhood are grain and oil. The red dye made from the native cochineal was formerly celebrated. In the time of the Moors Baeza was a flourishing city of 50,000 inhabitants, and the capital of a separate kingdom, but it never recovered from the sack of 1239. It is the birthplace of Gaspar Becerra, the celebrated sculptor and painter. Present population, about 11,000.

BAFFIN, WILLIAM, an able and enterprising English seaman, born in 1584. Nothing is known of his early life, and his fame rests entirely on the voyages undertaken by him during the years 1612 to 1616. In 1612 he accompanied Captain James Hall on his fourth voyage in search of the north-west passage, and in 1613 he commanded one of the English vessels engaged in the Greenland fisheries. In 1615 and 1616 Baffin made two voyages in the "Discovery" under Bylot, and on the second of them explored the large inlet, afterwards called Baffin's Bay. The only accounts of these expeditions were given by Baffin himself, and later investigators have thoroughly confirmed his descriptions. In 1618 he is said to have been mate in a voyage to Surat and Mocha; and in 1621 he was killed while attempting, in conjunction with a Persian force, to expel the Portuguese from Ormuz. (See Purchas's *Pilgrims* and the publications of the Hakluyt Society for 1849.)

BAFFIN'S BAY, or BAFFIN'S SEA, is properly neither a bay nor a sea, but part of the long strait or inlet which separates Greenland from the N.E. coast of America. It extends from about 69° to 78° N. lat. and from 54° to 72° W. long., and is connected by Lancaster Sound and Barrow's Strait with the Arctic Ocean. It was first explored in 1616 by the English navigator Baffin. The part of the strait to the south is known as Davis Strait, and the narrower channel to the north takes the name of Smith's Sound. The coasts are generally high and precipitous, and are deeply indented with gulfs. The most important island on the east side is Disco to the north of Disco Bay, where there is a Danish settlement. During the greater part of the year this sea is frozen, and it is navigable only from the beginning of June to the end of September. It is annually visited by vessels engaged in the whale and seal fishery. (See Petermann's *Mittheil.*, 1873, map 13, and Markham's *Cruise in Baffin's Bay.*)

BAGATELLE is an indoor game, probably derived from the old English shovel-board, described by Cotton in his *Compleat Gamester* (1674), though many consider that its invention is due to the French. Like billiards, chess, and draughts, its origin is not certainly known; but whatever its genesis, its name is undoubtedly French. Bagatelle games are played on an oblong board, usually from six to ten feet in length, by a foot and a half to three feet in width. The bed of the table, which is ordinarily of slate or mahogany, is covered with fine green cloth; and at the upper end, which is rounded, there are nine holes or cups, numbered from 1 to 9, thus

```
      5
   3     2
8     9     7
   4     6
      1
```

Into these holes ivory balls are driven by a cue in all respects similar to the instrument used in BILLIARDS, which see. The sides and circular end of the table are furnished with elastic cushions; and in some of the newer tables there is also a pocket on each side. Nine balls—eight white, and one red or black (sometimes four white, four red, and one black)—are used in the most popular of the several bagatelle games.

The ordinary game is played according to the following rules:—

1. Any number of persons may play, whether singly or in sides. 2. Each player strings for lead, and he who lodges his ball in the highest hole begins. In the case of partners, one only on each side need string for the lead. 3. The player who wins the lead takes the nine balls and plays them one after the other up the table from baulk, first striking at the red ball which is placed on the spot about a foot below the 1 hole. The object of the player is to lodge his own, or the coloured ball, or both balls, in the holes. 4. The red ball counts double when it is played into a hole; and for each white ball lodged or holed, a corresponding number of points is scored to that marked

in the cup. (Sometimes two coloured balls are used, in which case both count double.) 5. The red ball must be first struck, and the remainder of the balls are played up to the holes—the sum total of the holes made being the striker's score. 6. Any number of rounds may be played for the game, as agreed on at the commencement; and the player (or side) obtaining the highest aggregate score wins. 7. Any ball that rebounds beyond the baulk line, or is forced over the table, is not re-used in that round.

Sans Egal, or the French Game, is the next most generally played game on the bagatelle table. It is governed by the following laws:—1. The player who takes the lead (which is decided as in bagatelle) makes choice of four balls of either colour, and placing the black one on the spot, commences by striking it with a ball from baulk. 2. The other player then strikes up one of his balls, and so on alternately. 3. He who holes the black ball counts it towards his game, together with any number made by the white. 4. If either player hole his adversary's ball, the number scored by such ball, or balls, is marked to the other side. 5. The player who makes the greatest number of points in each round wins the game, and takes the lead in the next. The rule as to balls rebounding beyond the baulk line, or being forced off the table, is the same as in the preceding game.

The Cannon Game, sometimes played on a table without holes, consists entirely of cannons, that is to say, two balls struck in succession by the cue-ball. This game is played 50, 100, or 150 up, and the holes into which the balls fall are sometimes counted in addition to the cannon. Three balls only are used—a white, a spot-white, and a black ball. At starting the latter is placed on the spot, and the adversary's ball on a point equi-distant between the first and centre holes, 1 and 9. If the striker make a cannon, he goes on as long as he can score, but no hole can be counted without first making the cannon. To miss the white involves the loss of 1 point; and to miss the black ball, 5 points. The striker's break is ended when he fails to cannon, and then the other player goes on,—he who first gains the required number winning the game. When there are pockets to the table, two points are taken for every white ball pocketed, and three points for the red. Should the player's ball fall into a pocket before he make the cannon, the score is taken by the opponent. In the *Irish Cannon Game* the holes do not count, except by way of penalty; all points made by holing the balls being added to the score of the adversary. Sometimes, in both the cannon games two points are taken for a cannon from white to white and then to red, and three for a cannon from white to red and then to white; or, when two coloured balls are used, three points are taken for a cannon from the black to the red. Lately, bagatelle tables as much as 14 feet long by 6 feet wide have been made for the cannon game.

Mississippi is a game played on a bagatelle table with a bridge pierced with arches, each arch bearing a certain number—say, from 1 to 10 or 12. The balls are first played from the baulk against the cushion on to the bridge, which is placed just in front of the lowermost hole. The rules are —1. If the ball pass through the bridge, all the points indicated on the arch are counted towards the player's score, in addition to any points made by the ball falling into a hole beyond the bridge. The game may be played by two or more persons, and he who first makes the number of points agreed on—100, 200, 500, &c.—wins. A modification of this game is called

Trou Madame. In this the balls are played from the baulk straight up to the bridge without touching the cushion, and only the points marked upon the arches score,—all points made by the balls dropping into the holes beyond being scored to the opponent. Another variety, called

Cockamaroo, or Russian Bagatelle, is played on a table prepared with a number of pins, holes, arches, and bells, up to and through which the ball is played from the baulk end of the table. It is a childish amusement, requiring little skill, and therefore needing only the barest mention.

In playing the bagatelle games a much less degree of force is required for the stroke than is necessary for billiards. Some adepts are able to fill all the holes at one essay; first, by striking the red ball on the side, making a double hazard, say, into the 7 and the 8 holes, and then, either by playing direct at the holes or at the cushion, lodging each successive ball till the whole nine are pocketed. In this way, counting double for the red, as many as 54 points can be scored in a single round of the balls. When two coloured balls are used, of course a proportionally larger score is made. The cue should be held lightly between the fingers and thumb, not grasped in the palm of the hand; and much use may be made of the various strokes employed in billiards,—as the side, the screw, the twist, and the drag; for which terms see the article BILLIARDS. (G. F. P.)

BAGGESEN, JENS EMMANUEL, the most prominent literary figure in Denmark during the latter part of last century, was born on the 15th of February 1765, at Korsör. His parents were very poor, and before he was twelve he was sent to copy documents at the office of the clerk of the district. By dint of indomitable perseverance, he managed to gain an education, and in 1782 entered the university of Copenhagen. His success as a writer was coeval with his earliest publication; his *Comical Tales* in verse, poems that recall the *Broad Grins* that Colman the younger brought out a decade later, took the town by storm, and the struggling young poet found himself a popular favourite at twenty-one. He then tried serious lyrical writing, and his tact, elegance of manner, and versatility, gained him a place in the best society. This sudden success received a blow in 1788, when a very poor opera he had produced was received with mockery, and a reaction against him set in. He left Denmark in a rage, and spent the next years in Germany, France, and Switzerland. In the country last mentioned he married, began to write in German, and published in that language his next poem, *Alpenlied*. In 1790 he returned to his mother-country, bringing with him as a peace-offering his fine descriptive poem, the *Labyrinth*, in Danish, and was received with unbounded homage. The next twenty years were spent in incessant restless wanderings over the north of Europe, Paris latterly becoming his nominal home. He continued to publish volumes alternately in Danish and German. In 1811 he returned to Copenhagen to find the young Ohlenschläger installed as the great poet of the day, and he himself beginning to lose his previously unbounded popularity. Until 1820 he resided in Copenhagen, in almost unceasing literary feud with some one or other, abusing and being abused, the most important feature of the whole being Baggesen's determination not to allow Ohlenschläger to be considered a greater poet than himself. He then went back to his beloved Paris, where he lost his wife and youngest child, and fell at last into a state of hopeless melancholy madness. In 1826, having slightly recovered, he wished to see Denmark once more, but died at Hamburg on his way, on the 3d of October, and was buried at Kiel. His many-sided talents achieved success in all forms of writing, but his domestic, philosophical, and critical works have long ceased to occupy attention. A little more power of restraining his egotism and passion would have made him one of the wittiest and keenest of modern satirists, and his comic poems are deathless. The Danish literature owes Baggesen a great debt for the firmness, polish, and form which he introduced into it—his style being always finished

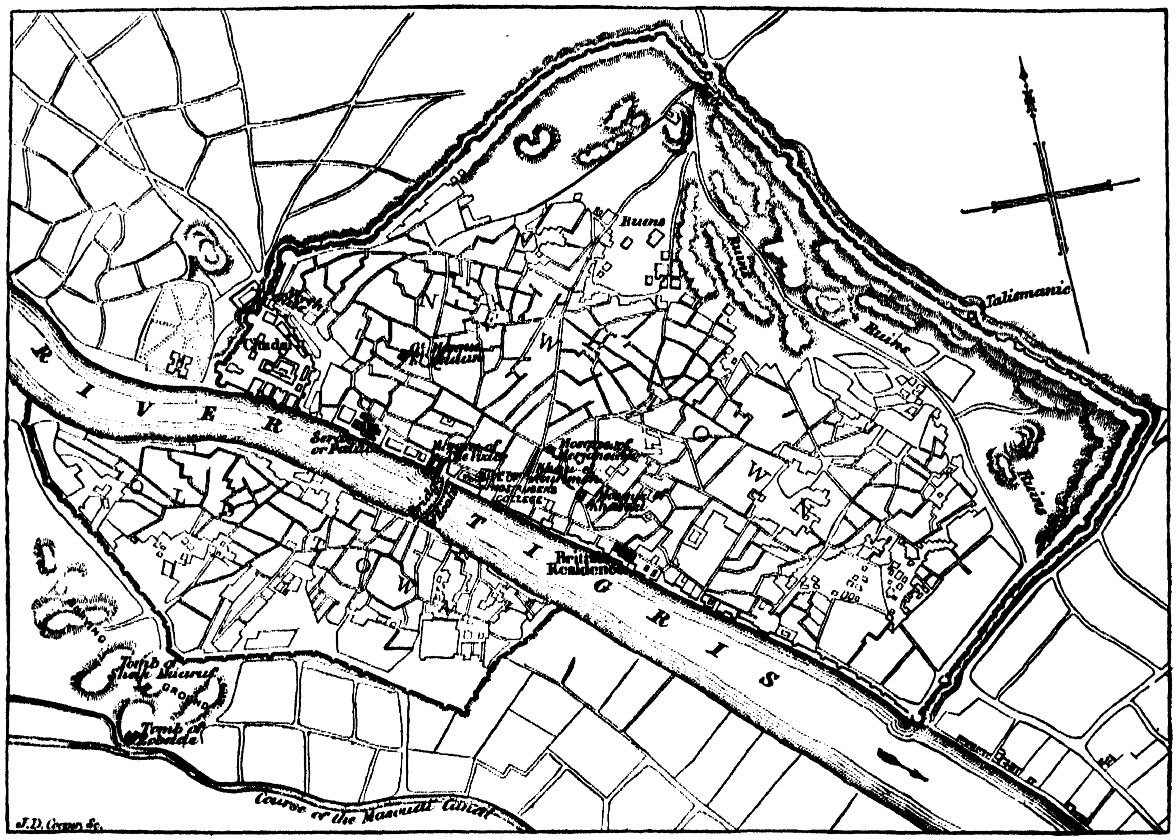
and elegant. With all his faults he stands as the greatest figure between Holberg and Ohlenschläger. Of all his poems, however, the loveliest and best is a little simple song, called *There was a time when I was very little*, which every Dane, high or low, knows by heart, and which is matchless in its simplicity and pathos. It has outlived all his epics. (E. W. G.)

BAGHDAD, a Turkish pashalic or government of Asia, computed to have an area of above 100,000 square miles. It stretches in a N.W. direction, from the mouth of the Shatt-el-Arab at Bussorah, to Merdin, situated near the source of the Tigris; and from the confines of Persia to the banks of the Khabour, which separates it from the pashalic of Diarbekir. Its general boundaries are the Euphrates and the Arabian desert of Nejd to the W. and S., Kusistan and Mount Zagros to the E., the pashalic of Diarbekir to the N.W., and Armenia with the territories of the Kurdish chief of Julamerick to the N. This great tract comprehends ancient Babylonia and the greatest part of Assyria proper. The first includes the space enclosed by the Tigris and the Euphrates, which is also known under the general appellation of Mesopotamia; and the second, that which is beyond the Tigris, commonly called Lower Kurdistan. This tract of country is an extensive and very fertile plain, and is watered by the Tigris and the Euphrates, which at Baghdad approach within 25 miles of each other, and afford an inexhaustible supply of the finest water. Only some parts of these fertile districts, however, are cultivated, as the population consists in many places of wandering Arabs, who are averse to agriculture, and who, in their vagrant life of idleness and rapine, neglect all the natural advantages of the country. The most productive portion of the pashalic is on the banks of the Shatt-el-Arab, in the neighbourhood of Bussorah. This tract, for upwards of 30 miles below that city, is well cultivated, and yields vast quantities of dates, wheat, barley, and various kinds of fruits. The banks of the Euphrates produce abundant crops of dry grain. Higher up the Euphrates, the country which is possessed by the Arabs is a low marshy tract, formed by the expansion of the Euphrates, and is famed for plentiful crops of rice. Among the mountainous districts of the Upper Euphrates the country is highly picturesque and beautiful; it is watered by the River Mygdonius (the Gozan of Scripture), and is in a tolerable state of cultivation. It produces in abundance the finest fruits, such as grapes, olives, figs, pomegranates, which are considered the most delicious in the East; apples, pears, apricots of an inferior quality; and the finest dates, on which the inhabitants, as in other parts of Asia, depend in many cases for subsistence. The domestic animals are, the horse, for which the country has long been famed, the ass, camel, dromedary, buffalo, and mule. Of the wild animals, the lion, the hyena, the jackal, the wolf, and the wild boar, are common; and antelopes are very numerous. Hares are plentiful, but foxes are seldom seen. All sorts of poultry are bred except the turkey. On the cultivated lands, and on the borders of the rivers, the black partridge is met with in great numbers. Snipes and almost every species of wild fowl may be found in the marshes, and pelicans on the banks of the Euphrates and Tigris. In addition to these two rivers, the country is watered by the Khabour or Chaboras, formed by the junction of several small streams about ten miles to the S.W. of Merdin, and by the Mygdonius, or Gozan, the Hermas of the Arabs, which used formerly to discharge a part of its waters into the Euphrates through the Khabour, and a part into the Tigris through the Thirthar, passing by Hatra, but which is now entirely lost in a salt marsh at the foot of the Singar hills.

In ancient times the plain of Mesopotamia was occupied by the great and wealthy cities of Nineveh, Babylon, Seleucia, Ctesiphon, &c., and was in a high state of cultivation. It was intersected by many well-constructed canals and other works, which, in dispersing over the country the superfluous waters of the Tigris and Euphrates, proved extremely useful to agriculture. These works are now all ruined, and not a vestige remains of many of the canals, while the course of others can only be faintly traced in their imperfect remains. One canal, however, called El-Hye, still exists; it connects the Euphrates and the Tigris exactly half-way between Bussorah and Baghdad, and is navigable in spring for large boats.

BAGHDAD, a city of Asia, formerly the capital of the empire of the caliph, and long renowned for its commerce and its wealth, is situated on an extensive and desert plain, which has scarcely a tree or village throughout its whole extent; and though it is intersected by the Tigris, it stands mostly on its eastern bank, close to the water's edge. Old Baghdad on the W. is now considered as merely a suburb to the larger and more modern city on the eastern shore, the former containing an area of only 146 acres, while the latter extends over 591. It has, however, numerous and extensive streets, well furnished with shops, and is protected by strong walls, with three gates opening towards Hillah on the Euphrates and Kazimeen. Beyond these modern bulwarks vestiges of ancient buildings, spreading in various directions, are visible in the plain, which is strewed with fragments of brick, tiles, and rubbish. A burying-ground has extended itself over a large tract of land formerly occupied by the streets of the city; and here is the tomb of Zobeide, the favourite wife of Haroun el Raschid, built of brick, of a high octagonal shape, and surmounted by a lofty superstructure in the form of a cone. It was originally built in 827 A.D., but has been frequently restored. The two towns of Old and New Baghdad are connected by a bridge of thirty pontoons. The form of the new city is that of an irregular oblong, about 1500 paces in length by 800 in breadth; and a brick wall, about five miles in circuit, encloses the town on both sides of the river. This wall, which is built of brick, has been constructed and repaired at different periods; and, as in most other works of the same nature in Mahometan countries, the oldest portion is the best, and the more modern the worst part of the fabric. At the principal angles are large round towers, with smaller towers intervening at short distances; and on these large towers batteries are planted, with brass cannon of different calibre, badly mounted. Of two of these angular towers Mr Buckingham remarked that the workmanship is equal to any ancient masonry that he had ever seen. The wall has three gates—one on the S.E., one on the N.E., and a third on the N.W. of the city; and it is surrounded by a dry ditch of considerable depth. A fourth gate on the northern side, which has been closed since the capture of the city by Sultan Amurath IV. in 1638, is a good specimen of Saracenic brick-work. It was formerly called "the white Gate," but is now known as the "*Bab-el-Tilism*," or "Talismanic Gate," from a fine Arabic inscription in relief on a scroll border round the tower, which bears the date of 618 A.H. (1220 A.D.) The town has been built without the slightest regard to regularity. The streets are even more intricate and winding than those in most other Eastern towns; and, with the exception of the bazaars and some open squares, the interior is little else than a labyrinth of alleys and passages. The streets are unpaved, and in many places so narrow that two horsemen can scarcely pass each other; and as it is seldom that the houses have windows facing the great public thoroughfares, and the doors are small and mean, they present on both sides the

gloomy appearance of dead walls. All the buildings, both public and private, are constructed of furnace-burnt bricks, of a yellowish-red colour, taken chiefly from the ruins of other edifices, as their rounded angles evidently show. A house is generally laid out in ranges of apartments opening into a square interior court, and furnished with subterranean rooms called *serdaubs*, into which the inhabitants retreat during the day for shelter from the intense heats of summer; and with terraced roofs, on which they take their evening meal, and sleep in the open air. Occasionally in the months of June, July, and August, when the *Sherki* or south wind is blowing, the thermometer at break of day is known to stand at 112° Fahr.; while at noon it rises to 119°, and a little before two o'clock to 122°, standing at sunset at 117°, and at midnight at 114°. But this scale of temperature is exceptional. During the summer months the wind is usually in the north-west, and the air, though hot, is fresh and exhilarating, the thermometer ranging from about 75° at sunrise to 107° at the hottest time of the day. The interiors of the houses of the rich are splendidly furnished, and ornamented in the ceilings with a sort of chequered work, which has a handsome appearance. A great portion of the ground within the walls of the town is unoccupied by buildings, especially in the north-eastern quarter; and even in the more populous parts of the city near the river, a considerable space between the houses is occupied by gardens, where pomegranates, grapes, figs, olives, and dates grow in great abundance, so that the city when seen from a distance has the appearance of rising out of the midst of trees.



Ground-Plan of the Enceinte of Baghdad.

Reduced from Survey made by Commander F. Jones and Mr W. Collingwood of the Indian Navy, 1853–54.

The principal public buildings in Baghdad are the mosques, the khans or caravanserais, and the serai or palace of the pasha. The palace, which is situated in the north-western quarter of the town, not far from the Tigris, is distinguished rather for extent than grandeur. It is a comparatively modern structure, built at different periods, and forming a large and confused pile, without proportion, beauty, or strength. There are no remains of the ancient palace of the caliphs.

In all Mahometan cities the mosques are conspicuous objects. The number in Baghdad is above 100; but of these not more than thirty are distinguished by the characteristic minarets or steeples, the rest being merely chapels and venerated places of prayer. The most ancient of these mosques was erected in the year of the Hegira 633, or 1235 of the Christian era, by the Caliph Mustansir. All that remains of the original building is the minaret, and a small portion of the outer walls; the former a short, heavy erection, of the most ungraceful proportions, built of bricks of various colours, diagonally crossed. The jamah or mosque of Merjaneeah, not far distant from the former, though the body of it is modern, has some remains of old and very rich arabesque work on its surface, dating from the 14th century. The door is formed by a lofty arch of the Pointed form, bordered on both sides by rich bands exquisitely sculptured, and having numerous inscriptions. The mosque of Khaseki, supposed to have been an old Christian church, is chiefly distinguished by the niche for prayer, which, instead of a simple and unadorned recess, is crowned by a Roman arch, with square pedestals, spirally fluted shafts, a rich capital of flowers, and a fine fan or shell-top in the Roman style. Around the arch is a sculptured frieze; and down the centre, at the back of the niche, is a broad band, richly sculptured with vases, flowers, &c., in the very best style of workmanship,—the whole executed on a white marble ground. The building in its present state bears the date of 1682 A.D., but the sculptures which it contains belong probably to the time of the early

caliphs. The mosque of the vizier, near the Tigris, has a fine dome and lofty minaret; and the great mosque in the square of El Meidan is also a noble building. The others do not merit any particular notice. The domes of Baghdad are mostly high, and disproportionately narrow. They are richly ornamented with glazed tiles and painting, the colours chiefly green and white, which, being reflected from a polished surface, impart more liveliness than magnificence to the aspect of these buildings. In the opinion of Mr Buckingham, they are not to be compared to the rich and stately domes of Egypt, as the minarets, although they have the same bright assemblage of colours, are far from being equal "to the plain and grave dignity of some of the Turkish towers at Diarbekir, Aleppo, and Damascus, or to the lighter elegance of many of those in the larger towns on the banks of the Nile."

There are about thirty khans or caravanserais in Baghdad, all of inferior construction to those in the other large towns of Turkey. The only remarkable building of this class is called *Khan-el-Aourtmeh*, and adjoins the Merjaneeah mosque, to which it formerly belonged. The vaulted roof of this building is a fine specimen of Saracenic brick-work, and like the adjoining mosque, bears the date of 1356 A.D. It is said, however, to occupy the site of an ancient Christian church. The bazaars, which are numerous, are mostly formed of long, straight, and tolerably wide avenues. The one most recently built is the largest and the best; still it has an air of meanness about it that is not common in the bazaars of large Turkish cities. It is long, wide, and lofty, and well filled with dealers and wares of all sorts. Several of these bazaars are vaulted over with brick-work; but the greater number are merely covered with flat beams which support a roof of straw, dried leaves, or branches of trees and grass. There are about fifty baths in Baghdad, which are also very inferior in their accommodations to those in the other large towns of Mesopotamia. The only other Mahometan remains which it is necessary to mention are—1. The Tekiyeh, or shrine of the Bektash dervishes, on the western bank of the river. The shrine is in ruins, but it contains a fine Cufic inscription now mutilated, which bears the date of 333 A.H. (or 944 A.D.) 2. The tomb of the famous Maaruf-el-Kerkhi, in the immediate vicinity, dating from 1215 A.D. 3. In Eastern or New Baghdad the college of Mustansir, near the bridge, now in ruins, but bearing a fine inscription dated 630 A.H. (or 1233 A.D.) 4. The shrine of the famous Saint Abdul Kadir, which is visited by pilgrims from all parts of the Mahometan world. The original tomb was erected about 1252 A.D., but the noble dome which now canopies the grave dates from about two centuries later. An aqueduct, the only one in the city, conveys water from the river to this shrine. None of the other mosques or tombs require particular notice.

Baghdad is about 500 miles from the mouth of the Tigris (following its course), and about 400 from Bussorah; and with the latter place it carries on a constant communication by means of boats of from twenty to fifty tons burden, though the river is navigable for larger vessels. With a northerly wind these boats will make the passage to Bussorah in seven or eight days; in calms, when they have merely the aid of the current, the passage occupies from ten to fifteen days. Sir R. K. Porter mentions that the stream of the Tigris runs at the rate of seven knots an hour. This, however, is probably during floods, since, with such a powerful current, a boat could not occupy ten or fifteen days on its passage from Baghdad to Bussorah. In coming up the stream, thirty or forty days are required to reach Baghdad. Of late years, however, steam communication has almost entirely superseded the use of the native craft between Baghdad and Bussorah. British steamers were first placed upon the Tigris and Euphrates by Colonel Chesney in 1836, and, with the sanction of the Turkish Government, they have ever since been maintained there, one small vessel of the Indian naval service being attached to the British Residency, and two commercial steamers belonging to an English company being employed in navigating the Tigris for trade purposes. The Turks have also endeavoured to establish a line of mercantile steamers of their own between Baghdad and Bussorah, but they have not hitherto been very successful. The smaller craft, used for bringing supplies of provisions and fruit to the city, are circular boats of basket-work, covered with skins, the same that have been employed from the remotest antiquity. The Euphrates and the Tigris are liable to spring floods; and the streams of both rivers being sometimes joined, inundate the desert plain on which Baghdad stands, when the city appears like an island in the midst of the sea. The inhabitants are supplied with water from the Tigris, which is brought to their houses in goats' skins, the convenience of water-works, cisterns, and pipes being entirely unknown.

Baghdad has much declined from its ancient importance. It was formerly a great emporium of Eastern commerce; and it still receives, by way of Bussorah, from Bengal the manufactures and produce of India, which are distributed over Arabia, Syria, Kurdistan, Armenia, and Asia Minor. At the same time the inland trade from Persia and the East has fallen off. The productions and manufactures of Persia, which were intended for the Syrian, Armenian, and Turkish markets, and were sent to Baghdad as a central depôt, now reach Constantinople by the more direct route of Erzeroum and Tocat. Wealth, indeed, appears to be deficient among all classes, and Baghdad has many symptoms of a decayed city. It must, however, be noted that a very considerable trade has sprung up of late years between the European markets and Baghdad, several English houses being established in the city, who import goods direct from London and Liverpool, *via* the Suez Canal and Bussorah, and French, German, Swiss, and Greek merchants being also engaged in the traffic. The staple articles of export are dates, wool, and grain, to which may be added cloth of various kinds, drugs, dye-stuffs, and miscellaneous productions. A very considerable trade in horses is also carried on. The total value of the exports in 1870–71 reached about £46,900, while the imports for the same year were stated at upwards of £285,000. There is a considerable manufacture of red and yellow leather, which is made into shoes, and finds a ready sale.

The population is a mixture of nations from various quarters of the East. The chief officers of Government, whether civil or military, are of the families of Constantinopolitan Turks, though they are mostly natives of the city; the merchants and traders are almost all of Persian or Arabian descent; while the lower classes consist of Turks, Arabs, Persians, and Indians. There are some Jews and Christians, who still remain distinct from the other classes; while the strangers in the town are Kurds, Persians, and desert Arabs in considerable numbers. The dress of the Baghdad Turks is not nearly so gay or splendid as that of their northern countrymen; and the costume of the residents is, upon the whole, unusually plain in comparison with that of other Asiatics. As every nation retains its own peculiar dress, it may be easily conceived what an amusing variety of costume must be seen in the streets of Baghdad. The dress of the females is as mean as that used in the poorest villages of Mesopotamia; women of all classes being enveloped in a blue checked cloth, such as is worn by the lowest orders in Egypt, and having their faces covered by hideous veils of black horse-hair.

Baghdad is governed by a pasha, assisted by a council. He was formerly chosen from the ranks of the Georgian

Mamelukes, but is now always selected from among the highest officers of the Constantinople court, his term of office being usually for four or five years. He is also governor-general of Irak, and possesses supreme authority from Diarbekir to Bahrein, though he does not under ordinary circumstances interfere with the subordinate governments of Mosul and Kurdistan.[1]

The East India Company used to maintain a resident in Baghdad with a large establishment, and his post is now replaced by that of a consul-general and political agent. A French consul is also regularly appointed.

Until recently Baghdad was supposed to be entirely a Mahometan city, dating from the time of Al Mansúr; but Sir H. Rawlinson discovered in 1848, during an unusually dry season, when the rivers had fallen six feet below the ordinary low-water mark, that the western bank of the Tigris was lined with an embankment of solid brick-work, dating from the time of Nebuchadnezzar, as the bricks were each stamped with his name and titles; and it has been since remarked that in the Assyrian geographical catalogues of the time of Sardanapalus, one of the Babylonian cities bears the name of *Bagdad*, and may thus very possibly represent the after site of the capital of the caliphs. According to the Arabian writers, however, there were no traces of former habitation when Al Mansúr laid the foundation of the new city. It was adorned with many noble and stately edifices by the magnificence of the renowned Haroun el Raschid, who also built on the eastern side of the river, connecting the two quarters of the town by a bridge of boats. Under the auspices of Zobeide, the wife of that prince, and Jaffer the Barmecide, his favourite, the city may be said to have attained its greatest splendour. It continued to flourish and increase, and to be the seat of elegance and learning, until the 656th year of the Hegira (1277 A.D.), when Hulaku the Tatar, the grandson of Genghis Khan, took it by storm, and extinguished the dynasty of the Abbassides. The Tatars retained possession of Baghdad till about the year 1400 of our era, when it was taken by Timur, from whom the Sultan Ahmed Ben Avis fled, and finding refuge with the Greek emperor, contrived afterwards to repossess himself of the city, whence he was finally expelled by Kara Yusef in 1417. In 1477 his descendants were driven out by Usum Cassim, who reigned 39 years in Baghdad, when Shah Ishmael the First, the founder of the royal house of Seff, made himself master of it. From that time it continued for a long period an object of contention between the Turks and Persians. It was taken by Soliman the Magnificent, and retaken by Shah Abbas the Great; and it was afterwards besieged by Amurath the Fourth, with an army of 300,000 men. After an obstinate resistance, it was forced to surrender 1638 A.D.; when, in defiance of the terms of capitulation, most of the inhabitants were massacred. Since that period it has remained under a nominal subjection to the Turks. Achmet, the greatest of the pashas of Baghdad, and the first who rendered the pashalic independent of the Porte, defended the town with such courage against Nadir Shah, that the invader was compelled to raise the siege, after suffering great loss. Baghdad, according to Colonel Chesney, had 110,000 inhabitants previously to the great plague of 1830; but in 1853 Mr Layard estimated its population under 50,000. An estimate made in 1872 on a census taken in 1869 rises as high as 150,000, but this is in all probability an exaggeration (*v.* Allen's *Indian Mail*, 1874). Long. 44° 24′ E., lat. 33° 21′ N. Soc.* (1856). (H. C. R.)

BAGHERMI, or BAGIRMI, a district or kingdom of Central Africa, lying to the S. of Lake Chad and S.W. of Bornu. It extends about 240 miles from N. to S., and has a breadth of barely 150 miles. The surface is almost flat, with a slight inclination to the N., and the general elevation is about 950 feet above sea-level. The Shari, a large and always navigable river, forms the western boundary, and throws out an important effluent called the Bachikam, which passes through the heart of the country. The soil consists partly of lime and partly of sand, and is by no means unfertile. In many parts not a stone is to be seen. Negro-millet, sesamum, and sorghum are the principal grains in cultivation, but rice grows wild, and several kinds of grass or *poa* are used as food by the natives. Cotton and indigo are grown to a considerable extent, especially by Bornu immigrants. Among the trees the most important are the tamarind, the deleb-palm, the dum-palm, the hajilij or *Balanites ægyptiaca*, the sycamore, and the cornel. The country often suffers from drought, and is greatly plagued with worms and insects, especially ants of all kinds, red, black, and white. The *Kungjungjudu*, a sort of beetle which does great damage to the crops, is eaten by the natives. A large proportion of the people have their feet mutilated by the attacks of a small worm, which takes up its residence in the first joint of the little toe and eats it gradually away. The inhabitants of Baghermi are a vigorous, well-formed race, who, according to their own traditions, came from the Far East several centuries ago. They speak a language cognate with those spoken by the Sara, who dwell about two degrees further south, and the Dor, who are situated at the confluence of the Dyor with the White Nile. On their arrival they soon extended their power over the Fellata and Arabs already settled in the district, and after being converted to Mahometanism under Abd-Allah, their fourth king, they extended their authority over a large number of heathen tribes. The most important of these are the Sokoro, the Bua, the Nyillam, the Sara, the Tumok, and the Busso. They are almost all in a low state of civilisation, and practise strange superstitions—a belief in a god whom they identify with thunder being the greatest extent of their religion. They are subject to the barbarous raids of their Baghermian masters, who derive from them a constant supply of slaves with which to pay the tribute demanded from them in their turn by the sultan of Bornu. For our knowledge of this district we are principally indebted to Barth and Nachtigal; the former was for some time a prisoner in Masseña, the capital.

See Barth, *Travels in Northern and Central Africa in 1849–53*, vol. iii., and Nachtigal, in Petermann's *Mittheil.* for 1874, and in *Zeitsch. d. Ges. f. Erdkunde zu Berlin*, 1875.

[1] Besides the court of superior officers which assists the pasha in the general administration of the province, there is also a Mejlis, or mixed tribunal, for the settlement of municipal and commercial affairs, to which both Christian and Jewish merchants are admitted. Much, of course, depends on the individual character of the pasha, but, on the whole, justice is fairly administered, and with less disposition perhaps to press on the non-Mussulman portion of the population than in any other city of Asiatic Turkey. The Jewish and Christian communities, indeed, from their wealth, intelligence, and long standing in the country, enjoy an exceptionally favourable social position, and live on terms of equality with their Mahometan neighbours.

Baghdad is also the headquarters of the army of Irak, and regular troops to the amount of five or six thousand men of all arms are usually kept together in the city, while an equal force is distributed in small garrisons in the Arab and Kurdish districts. Baghdad, after paying all its expenses, remits about £100,000 per annum to the imperial treasury, but its resources are capable of almost indefinite development, and there is indeed no reason why the valleys of the Tigris and Euphrates should not, under an enlightened government, yield a revenue fully equal to that of the valley of the Nile.

BAGHMATI, a river of Hindustán, which has its source in the hills to the north of Kátmandu, the capital of Nepál, whence it flows in a southerly direction through the district of Tirhut in the province of Behar, and, receiving the waters of the Buchiá on its north bank, and of Burá Gandak on its south bank, joins the Ganges, after a course of 285 miles, in 25° 23′ N. lat. and 86° 34′ E. long., about 8 miles below the town of Monghir, but on the opposite bank.

BAGLIVI, Giorgio, an illustrious Italian physician, descended from a poor persecuted Armenian family, was born at Ragusa in 1669, and assumed the name of his adoptive father, Pietro Angelo Baglivi, a wealthy physician of Lecce. He studied successively at the universities of Salerno, Padua, and Bologna; and after travelling over Italy, he went in 1602 to Rome, where, through the influence of the celebrated Malpighi, he was elected professor of anatomy in the college of Sapienza. He died at Rome in 1707, at the early age of thirty-eight. A collection of his writings, which are all in the Latin language, was published in 4to in 1704, and has been several times reprinted in the same form. An edition in 2 vols. 8vo was published in 1788. Baglivi's work, *De Fibra Motrice*, is the foundation of that theory of medicine which was substituted by Hoffmann and Cullen for the Humoral Pathology.

BAGNACAVALLO, Bartolommeo, an Italian painter, who flourished about the beginning of the 16th century. His real name was Ramenghi, but he received the cognomen Bagnacavallo from the little village where he was born in 1484. He studied first under Francia, and then proceeded to Rome, where he became a pupil of Raffaelle. While studying under him he worked along with many others at the decoration of the gallery in the Vatican, though it is not known what portions are his work. On his return to Bologna he quickly took the leading place as an artist, and to him were due the great improvements in the general style of what has been called the Bolognese school. His works were considered to be inferior in point of design to some other productions of the school of Raffaelle, but they were distinguished by rich colouring and graceful delineation. They were highly esteemed by Guido and the Carracci, who studied them carefully and in some points imitated them. The best specimens of Bagnacavallo's works, the *Dispute of St Augustin* and a *Madonna with Child*, are at Bologna. He died in 1542.

BAGNÈRES-DE-BIGORRE (the *Vicus Aquensis* of the Romans), the capital of an arrondissement in the department of Hautes-Pyrénées, is situated on the left bank of the Adour, 13 miles S.E. of Tarbes. It is one of the principal watering-places in France, and is much admired for its picturesque situation and the beauty of its environs, particularly the valley of Campan, which abounds with beautiful gardens and handsome villas. The town is remarkably neat and clean, and many of the houses are built or ornamented with marble. Its thermal springs and baths are numerous and varied, and are very efficacious in debility of the digestive organs and other maladies. Their temperature is from 90° to 135° Fahr. The season commences in May and terminates about the end of October, during which time the population is more than doubled. Manufactures of woollen cloth, worsted, leather, pottery, and toys are carried on, and marble from the neighbouring quarries is wrought in the town. Greatly frequented by the Romans, and destroyed by the Gothic invaders, Bagnères begins to appear again in history in the 12th century, and rose into permanent importance under the reign of Jeanne d'Albert, the mother of Henry IV. Permanent population, about 9500.

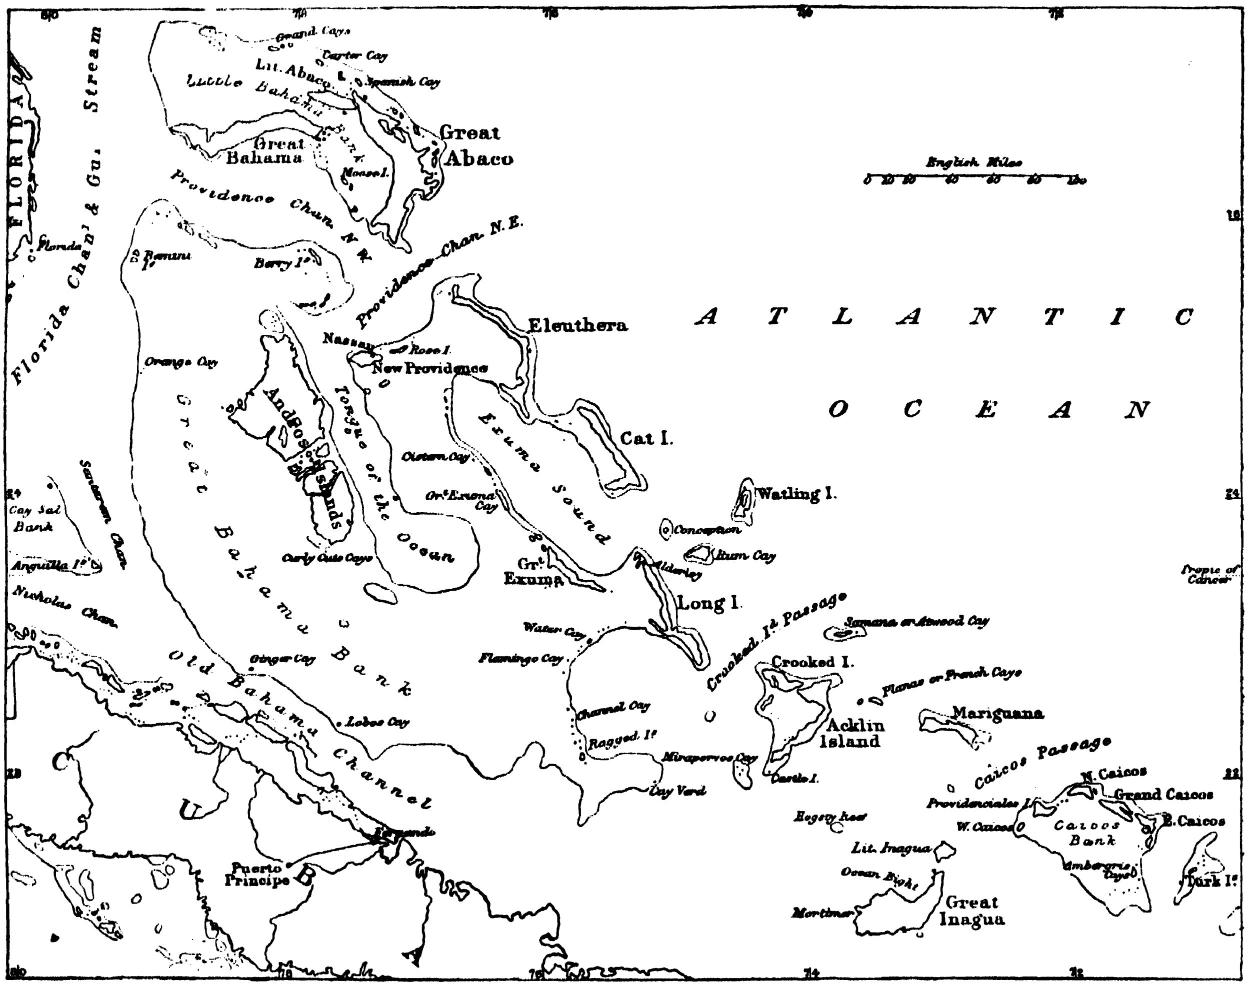
BAGNÈRES-DE-LUCHON, a small well-built town of France, department of Haute-Garonne, pleasantly situated in the valley of the Luchon, at the foot of the Pyrenees. It is celebrated for its sulphurous thermal springs, which vary in temperature from 88° to 180° Fahr. The bathing establishment is one of the most complete in Europe. The waters are employed with success in a variety of chronic affections, and about 10,000 patients visit the town annually. Resident population, about 3600.

BAGPIPE (Fr. *musette*, Ger. *Sackpfeife*, Ital. *cornamusa*), a musical instrument of unknown antiquity, which seems to have been at one time or other in common use among all the nations of Europe, and still retains its place in many Highland districts, such as Calabria, the Tyrol, and the Highlands of Scotland. The wind is generally supplied by a blowpipe, though in some cases bellows are used. These and other slight variations, however, involve no essential difference in character or construction, and a description of the great bagpipe of the Highlands of Scotland will serve to indicate the leading features of the instrument in all its forms. It consists of a large wind-bag made of greased leather covered with woollen cloth; a mouth-tube, valved, by which the bag is inflated with the player's breath; three reed drones; and a reed chanter with finger-holes, on which the tunes are played. Of the three drones, one is long and two are short. The longest is tuned to A, an octave below the lowest A of the chanter, and the two shorter drones are tuned each an octave above the A of the longest drone; or, in other words, in unison with the lowest A of the chanter. The scale of the chanter has a compass of nine notes, all natural, extending from G on the second line of the treble stave up to A in alt. In the music performed upon this instrument, the players introduce among the simple notes of the tune a kind of appoggiatura, consisting of a great number of rapid notes of peculiar embellishment, which they term *warblers*. No exact idea of these *warblers* can be formed except by hearing a first-rate player upon the Highland bagpipe. The history of the bagpipe can be clearly traced from the earliest periods by means of pictorial representations and references occurring in literature. The instrument probably consisted at first of the pipes without the bag, and in this form it is mentioned in Scripture (1 Sam. x. 5; Isa. v. 12; Jer. xlviii. 36), and was used by the Egyptians, the Greeks, and the Romans. The strain upon the player of these pipes was so great that he had to bandage up his lips and cheeks with a φορβεία or περιστόμιον, the Roman *capistrum*, a leathern muzzle or headstall. It seems very probable that the bagpipe derived its origin from these double and triple reed-pipes, by the after addition to them of a wind-bag made of the skin of a goat or kid, together with a valved *porte-vent*, in order to relieve the strain on the lungs and cheeks of the player. There are several evidences that the bagpipe was well known in the time of Nero. It is represented on a coin of that reign, copied in Montfaucon's *Antiquities*, and Suetonius (*Ner.*, 54) speaks of a promise made by Nero shortly before his death, that he would appear before the people as a bagpiper (*utricularius*). In mediæval Latin the instrument is designated the *Tibia utricularia*. Chaucer represents the miller as skilled in playing the bagpipe; and Shakspeare's familiar allusion to "the drone of a Lincolnshire bagpipe" is sufficient of itself to disprove the common notion that the instrument has always been peculiar to Scotland.

BAGRATION, Peter, Prince, a distinguished Russian general, descended from the noble Georgian family of the Bagratides, was born in 1765. In 1782 he entered the Russian army and served for some years in the Caucasus. In 1788 he was engaged in the siege of Oczacow, and afterwards accompanied Suwaroff, by whom he was highly esteemed, through all his Italian and Swiss campaigns. He particularly distinguished himself in 1799 by the capture of the town of Brescia. In the wars of 1805 his

achievements were even more brilliant. With a small force he withstood for several hours the united troops of Murat and Lannes, and though half his men fell, the retreat of the main army under Kutusoff was thereby secured. At Austerlitz he had the command of the advanced guard of Prince Lichtenstein's column, and at Eylau and Friedland he fought with the most resolute and stubborn courage. In 1808 he commanded in Finland, and in 1809 in Turkey, and was almost uniformly successful in his operations. In the famous Russian campaign of 1812 the corps under his leadership had been separated from the main army under Barclay de Tolly, and was defeated by Davoust at Mohilev. Bagration, however, succeeded in effecting the desired junction at Smolensk. He was mortally wounded in the bloody battle of the Borodino, 7th Sept. 1812, and died one month later.

BAHAMAS, or LUCAYAS, a very numerous group of islands, cays, rocks, and reefs, comprising an area of 3021 square miles, lying between 21° 42′ and 27° 34′ N. lat. and 72° 40′ and 79° 5′ W. long. They encircle and almost enclose the Gulf of Mexico, stretching more than 600 miles from the eastern coast of Florida to the northern coast of St Domingo, and are traversed by only three navigable channels,—1st, the Florida Channel to the N., which runs along the coast of the United States and lies to the westward of the whole Bahama group; 2d, the Providence



Sketch-Map of the Bahama Islands.

Channels, passing through the group to the N., and separating the Great and Little Banks; and 3d, the old Bahama Channel, which passes to the S. of the Great Bahama Bank, between it and Cuba. The islands lie for the most part on the windward edge of the Great and Little Banks, or of the ocean sounds or tongues which pierce them. The total number of islands is 29, while the cays are reckoned at 661, and the rocks at 2387. The principal islands are New Providence (which contains the capital Nassau), Abaco, Harbour Island, Eleuthera, Inagua, Mayaguana, St Salvador, Andros Island, Great Bahama, Ragged Island, Rum Cay, Exuma, Long Island, Crooked Island, Acklin Island, Long Cay, Watling Island, the Berry Islands, and the Biminis. Turk's Island and the Caicos, which belong geographically to the Bahama group, were separated politically in 1848. The formation of all the islands is the same,—calcareous rocks of coral and shell hardened into limestone, honeycombed and perforated with innumerable cavities, without a trace of primitive or volcanic rock; the surface is as hard as flint, but underneath it gradually softens and furnishes an admirable stone for building, which can be sawn into blocks of any size, these hardening on exposure to the atmosphere. The shores are generally low, the highest hill in the whole range of the islands being only 230 feet high. The soil, although very thin, is very fertile. On Andros Island and on Abaco there is much large timber, including mahogany, mastic, lignum vitæ, iron, and bullet woods, and many others. Unfortunately the want both of labour and of roads renders it impossible to turn this valuable timber to useful account. The fruits and spices of the Bahamas are very numerous,—the fruit equalling any in the world. The produce of the islands includes tamarinds, olives, oranges, lemons, limes, citrons, pomegranates, pine-apples, figs, sapodillas, bananas, sower-

sops, melons, yams, potatoes, gourds, cucumbers, pepper, cassava, prickly pears, sugar cane, ginger, coffee, indigo, Guinea corn and pease. Tobacco and cascarilla bark also flourish; and cotton is indigenous, and was woven into cloth by the aborigines.

It is a remarkable fact that except in the island of Andros, no streams of running water are to be found in the whole group. The inhabitants derive their water supply from wells, the rain-water in which appears to have some connection with the sea, as the contents of the wells rise and fall with the tide upon the neighbouring shore. The Bahamas are far poorer in their fauna than in their flora. It is said that the aborigines had a breed of dogs which did not bark, and a small coney is also mentioned. The guana also is indigenous to the islands. Oxen, sheep, horses, and other live stock introduced from Europe, thrive well, but of late years very little attention has been paid to stock rearing, and Nassau has been dependent upon Cuba for its beef, and on the United States or Nova Scotia for its mutton. There are many varieties of birds to be found in the woods of the Bahamas; they include flamingoes and the beautiful humming-bird, as well as wild geese, ducks, pigeons, hawks, green parrots, and doves. The water of the Bahamas swarm with fish, and the turtle procured here is particularly fine. In the southerly islands there are salt ponds of great value.

The story of the Bahamas is a singular one, and bears principally upon the fortunes of New Providence, which, from the fact that it alone possesses a perfectly safe harbour for vessels drawing more than 9 feet, has always been the seat of Government, when it was not the headquarters of lawless villainy. St Salvador (Cat Island, or as some suppose, Watling Island), however, claims historical precedence as the landfall of Columbus on his memorable voyage. He passed through the islands, and in one of his letters to Ferdinand and Isabella he said, "This country excels all others as far as the day surpasses the night in splendour; the natives love their neighbours as themselves; their conversation is the sweetest imaginable; their faces always smiling; and so gentle and so affectionate are they, that I swear to your highness there is not a better people in the world." But the natives, innocent as they appeared, were doomed to utter destruction. Ovando, the governor of Hispaniola, who had exhausted the labour of that island, turned his thoughts to the Bahamas, and in 1509 Ferdinand authorised him to procure labourers from these islands. It is said that reverence and love for their departed relatives was a marked feature in the character of the aborigines, and that the Spaniards made use of this as a bait to trap the unhappy natives. They promised to convey the ignorant savages in their ships to the "heavenly shores," where their departed friends now dwelt, and about 40,000 were transported to Hispaniola to perish miserably in the mines. From that date until after colonisation of New Providence by the English, there is no record of a Spanish visit to the Bahamas, with the exception of the extraordinary cruise of Juan Ponce de Leon, the conqueror of Porto Rico, who passed months searching the islands for "Bimini," which was reported to contain the miraculous "Fountain of Youth."

The deserted islands were first visited by the English in 1629, and a settlement formed in New Providence, which they held till 1641, when the Spaniards expelled them but made no attempt to settle there themselves. The English again took possession in 1667, and in 1680 Charles II. made a grant of the islands to George, Duke of Albemarle; William, Lord Craven; Sir George Carteret; John, Lord Berkeley; Anthony, Lord Ashley; and Sir Peter Colleton. Governors were appointed by the lords proprietors, and there are very copious records in the state papers of the attempts made to develop the resources of the island; but the repeated attacks of the Spaniards, and the tyranny and mismanagement of the governors, proved great obstacles to success. In July 1703 the French and Spaniards made a descent on New Providence, blew up the fort, spiked the guns, burnt the church, and carried off the governor, with the principal inhabitants, to the Havannah; and in October the Spaniards made a second descent, and completed the work of destruction. It is said that when the last of the governors appointed by the lords proprietors, in ignorance of the Spanish raid, arrived in New Providence, he found the island without an inhabitant. It soon, however, became the resort of pirates, and the names of many of the worst of these ruffians is associated with New Providence, the notorious Blackbeard being chief among the number. At last matters became so intolerable that the merchants of London and Bristol petitioned the Crown to take possession and restore order, and Captain Woods Rogers was sent out as the first Crown governor, and arrived at New Providence in 1718. Many families of good character now settled at the Bahamas, and some progress was made in developing the resources of the colony, although this was interrupted by the tyrannical conduct of some of the governors who succeeded Captain Woods Rogers. At this time the pine-apple was introduced as an article of cultivation at Eleuthera; and a few years subsequently, during the American war of independence, colonists arrived in great numbers, bringing with them wealth and also slave labour. Cotton cultivation was now attempted on a large scale. In 1783, at Long Island, 800 slaves were at work, and nearly 4000 acres of land under cultivation. But the usual bad luck of the Bahamas prevailed; the red bug destroyed the cotton crops in 1788, and again in 1794, and by the year 1800 cotton cultivation was almost abandoned. There were also other causes that tended to retard the progress of the colony. In 1776 Commodore Hopkins, of the American navy, took the island of New Providence; he soon, however, abandoned it as untenable, but in 1782 it was retaken by the Spanish governor of Cuba. The Spaniards retained nominal possession of the Bahamas until 1783, but before peace was notified New Providence was recaptured by a loyalist, Colonel Deveaux, of the South Carolina militia, in June 1783. In 1787, the descendants of the old lords proprietors received each a grant of £2000 in satisfaction of their claims, and the islands were formally reconveyed to the Crown. The Bahamas began again to make a little progress, until the separation of Turk's and Caicos Islands in 1848, which had been hitherto the most productive of the salt-producing islands, unfavourably affected the finances. Probably the abolition of the slave-trade in 1834 was not without its effect upon the fortunes of the landed proprietors.

The next event of importance in the history of the Bahamas was the rise of the blockade-running trade, consequent on the closing of the southern ports of America by the Federals in 1861. At the commencement of 1865 this trade was at its highest point. In January and February 1865 no less than 20 steamers arrived at Nassau, importing 14,182 bales of cotton, valued at £554,675. The extraordinary difference between the normal trade of the islands and that due to blockade-running, will be seen by comparing the imports and exports before the closing of the southern ports in 1860 with those of 1864. In the former year the imports were £234,029, and the exports £157,350, while in the latter year the imports were £5,346,112, and the exports, £4,672,398. The excitement, extravagance, and waste existing at Nassau during the days of blockade-running exceed belief. Individuals may have profited largely, but the Bahamas probably

benefited little. The Government managed to pay its debt amounting to £43,786, but crime increased, and sickness became very prevalent. The cessation of the trade was marked, however, by hardly any disturbance; there were no local failures, and in a few months the steamers and their crews departed, and New Providence subsided into its usual state of quietude. This, however, was not fated to last long, for in October 1866 a most violent hurricane passed over the island, injuring the orchards, destroying the fruit-trees, and damaging the sponges, which had proved hitherto a source of profit. The hurricane, too, was followed by repeated droughts, and the inhabitants of the out-islands were reduced to indigence and want. There was increase, however, in the production of salt. The exports as a whole fell off. Those of native produce, which in 1866 had been £77,604, were reduced in 1867 to £71,117, and the remaining exports of 1866, amounting to £184,372, were, in 1867, £156,131. The depression has continued almost to the present time (1875). The public debt paid off during the days of the blockade-running swelled again to a sum of £54,161, 13s. 2d., and the revenue until very lately was steadily on the decline. It was £47,530 in 1870, while the expenditure was £48,598, and in 1872 there was a further decrease of revenue to £37,574, with an expenditure of £39,000. In 1873 there was, however, an improvement. The revenue rose to £44,053, the expenditure being only £42,737. The improvement in the finances is due principally, it would seem, to the readjustment of the customs' duties. In a recent *Blue Book* it is stated that the Government in 1873 increased the duties on ale, brandy, gin, rum, and whisky by 50 per cent.; on cigars and tobacco, by 100 per cent.; and on wine by 200 per cent. As regards other articles the Assembly at the same time relieved the general consumer by reducing the 25 per cent. *ad valorem* duties to 15 per cent. They abolished the export duty on vessels in distress, and they reduced the tonnage and wharfage dues. They also abolished a licence fee, payable hitherto by the men employed as wreckers, and they repealed a special incometax levied upon public officers. The last colonial report expresses a hope and a belief that the sound financial condition to which the colony has been restored will continue. The hope, however, hardly seems justified at present by the commercial progress of the Bahamas. In 1870 the imports were of the value of £283,970. In 1872 they had fallen to £201,051, and in 1873 they had increased to £226,306. In like manner the exports of 1873 contrasted favourably with those of 1872, having increased from £136,224 to £156,613. But the increase in exports is due to the development of trade in articles, such as pineapples and oranges, the production of which is uncertain, since a season's crop may perish in a hurricane. The sponge trade is not so prosperous as it should be, the Spanish authorities, it appears, interfering with the spongers working on the reefs near Cuba; while the excessive duty levied in the United States on salt has almost paralysed the salt-making trade of the Bahamas. The total number of pine-apples exported to the United States and England in 1873 was 422,994 dozen, valued at £38,767. To this must be added the tinned fruit, a branch of industry introduced in 1872. Pine-apples in tins were exported in the following year to the number of 69,165 dozen, valued at £13,018, and cases of pine-apples from the same establishment to the value of £1712. The exportation of other fruit was—of oranges, 2,252,000, valued at £3822; of bananas, 7172 bunches, valued at £346; and about £700 worth of grape-fruit, shaddocks, lemons, limes, and melons. One great and profitable business at the Bahamas has decreased, and is not likely to flourish again. There has been of late years a marked diminution in the number of marine casualties, which in past times threw into the ports of the colony a large amount of valuable property, of which a great part was frequently exported. The erection of lighthouses, the diversion of trade from the southern ports of America, and the increased use of steam, have all tended to this decline of the wreckers' trade, and it is said that the people of Harbour Island, at one time the great stronghold of the wreckers, have now all turned their attention to the cultivation of pine-apples. In 1864 the number of wrecks reported was, including complete and partial, 67, while in 1871 it was but 39.

The colony is divided into 13 parishes, although the division is now used for civil purposes only. An Act to amend the ecclesiastical laws of the colony was assented to on the 1st of June 1869, and confirmed on the 7th of October 1869, and the Church of England at the Bahamas disestablished. The population of the islands taken at the census of 1871 was 39,162 (being an increase in the decennial period since 1861 of 3875), of whom 19,349 were males, and 19,813 females. With regard to race, it may be said that the native and coloured inhabitants now enormously outnumber the white colonists. The last return showing the varieties of race was published in 1826; the population was 16,033, of whom 4588 were white, 2259 coloured, and 9186 black; since then the proportion of coloured and black to white has increased. The health of the colony has been improving of late years; the death-rate of 1872 was only 17·9 in 1000. The total births were 1475 against 704 deaths. The climate of the Bahamas has always borne a reputation for salubrity. The mean of a series of daily observations of temperature for 10 years is as follows:—

Height of Thermometer in Degrees Fahr. at 9 A.M.

	Max.	Med.	Min.
January	75	70	66
February	76	71	66
March	78	72	66
April	81	75	68
May	84	78	71
June	88	81	74
July	88	82	75
August	88	81	75
September	86	81	75
October	82	77	73
November	79	74	70
December	77	73	69

The rainfall is heavy from May to October. During the winter months it is small, and from the month of November up to April the climate of New Providence is most agreeable. Advantage has been taken of this for many years by the inhabitants of the mainland of America, who can escape by a four days' voyage from the icy winter of New York to the perpetual summer of the Bahamas. New Providence has gained a name as a resort for the consumptive, and perhaps justly so far as the Anglo-Saxon race is concerned, but the Africans and coloured races suffer greatly from diseases of the lungs, and the black troops stationed at Nassau have always been notorious for the proportion of men invalided from consumptive disease. The principal religious denominations are the Wesleyan, Baptist, Church of England, and Presbyterian. The following figures represent approximately the number of persons generally attending the churches and chapels of the several denominations:—Wesleyan, 7370; Baptist, 7971; Church of England, 4250; Presbyterian, 300. There is no Roman Catholic place of worship in the islands, and the members of that church are very few in number. The constitution of the Bahamas consists of a governor, aided by an executive council of 9 members, a legislative council of 9 members,

and a representative assembly of 28 members. The qualifications of electors are full age, a residence of twelve months, six of which must have been as a freeholder, or a residence of six months and a payment of duties to the amount of £26, 0s. 10d. The qualification of members is possession of an estate of real or personal property to the value of £500. The executive is composed partly of official and partly of unofficial members; the latter have usually a seat in one of the branches of the legislature. There are 35 Government schools in the Bahamas, 5 of which are in New Providence, and 30 in the out-islands. These schools are managed by an education board composed of 5 or more members, with the governor as president. The legislative grant for educational purposes is £2200 a year, exclusive of the salary of the inspector of schools, who is borne upon the civil establishment on a salary of £200. The number of children on the books is about 3006, and there are 1200 in addition attending schools in connection with the Church of England. It is calculated that about 55 per cent. of the children between 5 and 15 attend school. The isolation of the settlements, the low salaries of the teachers, and the indifference of parents, are great obstacles to the spread of sound education in the Bahamas.

There are numerous lighthouses in the group, the principal being at Gun Cay, Abaco, Cay Sal, Great Isaacks, Cay Lobos, Stirrups Cay, Elbow Cay, Castle Island, Hoy Island, and Athol Island. The chief institutions of the Bahamas are to be found in New Providence. They include a savings' bank, a public library, a well-conducted newspaper press, the Agricultural Society, Bahama Institute, Fire Brigade, the New Providence Asylum, Public Dispensary, St Andrew's Charitable Society, a provincial grand lodge of freemasons, &c. There are also libraries at Dunmore Town, in Harbour Island, at Matthew Town, Inagua, at New Plymouth, at Abaco, &c. (J. T. W. B.)

BAHIA, a province of the Brazilian empire, situated on the S.E. coast, and extending from the Rio Grande do Belmonte in the S. to the Rio Real in the N. It is bounded by Sergipe and Pernambuco on the N., by Piauhi on the N.W., by Goyaz on the W., and on the S. by Minas Geraes and Espirito Santo. It has an area of 202,272, square miles, and its population is stated at 1,450,000. Bahia sends 14 deputies to the general assembly of the empire, and 7 senators to the upper house, while its own legislative assembly consists of 36 members. Besides Bahia the capital, Olivença, Branca, Jacobina, and Joazeira are important towns. A chain of mountains, broken into numerous sierras, runs from N. to S. through the province at the distance of 200 miles from the coast, while the intermediate district gradually rises in successive terraces. The maritime region, the so-called *Reconcavo*, is remarkably fertile, and is studded with thriving towns and villages, but the interior is often very dry and barren, and is only thinly peopled in many places with wandering Botacudos. The main sources of the wealth of the province are cotton, coffee, sugar, and tobacco, all of which are cultivated with the greatest success. Mandioc, rice, beans, and maize are grown; also jalap, ipecacuanha, and saffron, as well as oranges, mangoes, and various other fruits. A large portion is still covered with primeval forest, but the woodman is rapidly diminishing the extent. The mineral wealth of the province is but partially explored and still more partially utilised. In 1844 diamond mines were discovered to the N. of the River Peraguass, and, till the deposits near the Cape of Good Hope were brought to light, afforded employment to a large number of *garimpeiros* or "washers." The discovery of amethysts at Catité in 1872 attracted numerous searchers; and about the same time coal was found in the island of Itaparica. Gold is present in the alluvium of the River San Francisco.

BAHIA, or, in full, San Salvador da Bahia de todos os Santos, a large city, and, till 1763, the capital of Brazil, is situated on the S.E. coast on the Bay of All Saints, from which it takes its name, in 13° S. lat., and 38° 20′ W. long. Built partly along the foot and partly on the top of a steep hill, it consists of an upper and lower town, communication between the two being effected by large flights of steps, and since 1873 by a powerful hydraulic elevator. The carrying of goods and passengers up and down these stairway-streets affords employment to a large number of negro porters and chairmen. The lower town, or Praya, consists mainly of one long and narrow street, with still narrower and more tortuous lanes. The houses are built of stone, and many of them are several stories high. This is the business part of the city, where are situated the quays, docks, warehouses, custom-houses, exchange, and arsenal; and here the sailors, porters, and lower classes generally reside. The church of *Nostra Señora da Praya* is remarkable as having been built of stones that were hewn in Lisbon and shipped across the ocean. The upper city has wide and well-paved streets, open squares, and pleasant promenades, adorned with orange trees and bananas. The most important is the *Passeio Publico*, which was opened in 1814, and overlooks the beautiful bay. There is no city in Brazil that can vie with Bahia in the nomber and splendour of its ecclesiastical buildings, among which the Jesuits' college, now used as a hospital, and the cathedral, which is built of marble, are pre-eminent. There are likewise numerous educational institutions, including a lyceum (in which Latin, Greek, French, and English, mathematics, philosophy, &c., are taught), a theological seminary, and a medical academy, which is supported by the imperial Government, and has about 400 students. The museum and public library also deserve mention. Among the buildings connected with the civic and commercial activity of the city are the government-house, the court-house, the mint, and the town-house; also the *Alfandega*, where all foreign importations have to be entered, and the *Consolado*, where all native productions are registered for exportation. There are likewise a number of banks and commercial associations of various kinds. Bahia has long been a place of great traffic. The streets of the upper city are very inconveniently paved, but the city and its suburbs are now connected by street railways, two running in the upper town and one in the lower. Bomsim is the name of the northern suburb, and Victoria that of the southern; the foreign merchants for the most part reside in the latter. The commerce principally consists in the exportation of cotton, coffee, sugar, rum, tobacco, and rosewood, and the importation of miscellaneous foreign goods. The value of the imports in 1870 was £1,671,676, of which £885,206 belonged to Britain. The exports of the same year were valued at £1,790,928. The bay is one of the finest in America, and is well defended by forts. The entrance is protected by the large island of Itaparica, which has upwards of 16,000 inhabitants, of whom more than 7000 are collected in the town of San Gonzalo. A large number of these are employed in the whale-fishery, which has greatly fallen off, however, from its former prosperity.

Bahia was visited in 1503 by Amerigo Vespucci. The first settlement was founded and called San Salvador by Diego Alvarez Correa, who had been shipwrecked on the coast; but the Portuguese governor who gave formal existence to the city was Thomas de Souza, who landed in 1549. It owed its increase to the Jesuits, who defended it against the English in 1588. In 1623 it fell into the hands of the Dutch, who held it for two years. In 1823 it was surrendered by the Portuguese to the Brazilian nationality. A revolution, which broke out in the city in 1837, was suppressed by the imperial Government. The

first printing-press was introduced in 1811, and the first sugar-mill in 1823. In 1858 railway communication was established to Joazeiro.

BAHRDT, Karl Friedrich, a German theologian, distinguished for his extreme rationalism and his erratic life, was born in 1741 at Bischofswerda, of which place his father, afterwards professor of theology at Leipsic, was for some time pastor. He was educated chiefly at the celebrated school of Pforta, and afterwards entered the university of Leipsic, where he studied theology, and at first attached himself to the strongly orthodox party headed by Crusius. After graduation he lectured for a time as adjunct to his father, and then with the rank of catechist proceeded to Leipsic, where he became exceedingly popular as a preacher, and was appointed extraordinary professor of Biblical philology. During this period of his life he published a popular book of devotions, called the *Christian in Solitude*. In 1768 the notorious irregularity of his conduct necessitated his resignation and his departure from Leipsic. By some influence he obtained a professorship of Biblical antiquities in the philosophical faculty of the new university of Erfurt, and having procured a theological degree from Erlangen, he again began to read theological lectures. His orthodoxy had by this time completely vanished; he was an avowed rationalist of the extreme school, and with great diligence and ability sought to popularise the principles of his creed. At the same time his bitter and quarrelsome disposition embroiled him with his colleagues, and in 1771 he left Erfurt, but obtained another professorship at Giessen. Here also the bold expression of his opinions cut short his tenure of office; in 1775 he resigned and became director of Von Salis's educational establishment, the philanthropin at Marschlins, a post he held for only one year. For a brief period he acted as general superintendent at Dürkheim, and then endeavoured, but unsuccessfully, to set up an educational institution at Heidesheim. He had now become most obnoxious to the German Government, who prohibited him from lecturing or publishing any work on theology, or from holding any professorial office. In 1779 he took refuge in Halle, where he resided for ten years, lecturing in the forenoon on moral philosophy, and officiating in the afternoon as landlord of a public-house which he had opened at the gate of the town, and which was largely patronised by the students. In 1789 he was arrested, partly on account of a pasquinade he had written upon the Prussian religious edict, and was condemned to two years' imprisonment. The period of his confinement, reduced by the king to one year, was employed by Bahrdt in writing memorials of his life and opinions. After his release he continued his former course of life, and died after a severe illness, 23d April 1792. His numerous works, including a translation of the New Testament, are comparatively worthless, and are written in an offensive tone. He has been well called by Herzog a caricature of the rationalism of the 18th century.

BAHREIN, the principal island of a cluster in the Persian Gulf, in an indentation of the Arabian coast. It is about 70 miles long and nearly 25 broad, and is very flat and low except towards the east, where a range of hills attain an elevation of 800 or 900 feet. The climate is mild, but humid, and rather unhealthy. The soil is for the most part fertile, and produces rice, pot herbs, and fruits, of which the citrons are especially good. Water is abundant, but frequently brackish. Fish of all kinds abound off the coast, and are very cheap in the markets. The inhabitants are a mixed race of Arab, Omanite, and Persian blood, slender and small in their physical appearance; they possess great activity and intelligence, and are known in all the ports of the Persian Gulf for their commercial and industrial ability. The traffic in the island itself is great and various, the harbour of Manama, which admits vessels of 200 tons, being largely frequented by ships from Persia, Sindh, India, &c. This town, which has in some respects supplanted the older and more inland Ruffin, is well built, and contains about 25,000 inhabitants; and there are besides about 15 villages in the island. There is a city of almost equal extent in the neighbouring and smaller island of Mohanek, but the trade is not so great. Bahrein has from a remote period been famous for its pearl fishery, which produces the finest pearls in the world. The Portuguese obtained possession of the islands in 1507, but were driven from their settlements in that quarter by Shah Abbas in 1622. The islands afterwards became an object of contention between the Persians and Arabs, and at last the Arabian tribe of the Athubis made themselves masters of them in 1784. Since then they have been for some time subject more or less to the Wahabees, whose interference has greatly damaged the commerce of the ports, and led to extensive emigration of the inhabitants. (See Palgrave, in *J. Roy. Geo. Soc.*, vol. xxxiv.)

BAIÆ, an ancient town of Campania, Italy, situated between the promontory of Misenum and Puteoli, on the Sinus Baianus, and famous for its warm springs and baths, which served the wealthier Romans for the purposes both of health and pleasure. The variety of these baths, the mildness of the climate, and the beauty of the landscape, captivated the minds of the opulent nobles. The habitations at first were small and modest; but increasing luxury added palace to palace, and enterprising architects, supported by boundless wealth, laid the foundations of new erections in the sea. From being a place of occasional resort for a season, Baiæ grew up into a city, and the confluence of wealthy inhabitants rendered it as much a miracle of art as it had before been of nature, though it never attained the rank of a *municipium*, but continued to be dependent on Cumæ. C. Marius, Lucullus, Pompey, and Julius Cæsar are among the most remarkable of those who gave éclat to Baiæ during the republic; and at a later period it was a favourite resort of Nero, Caligula, Hadrian, and Severus. It flourished till the days of Theodoric the Goth; but its destruction followed quickly upon the irruption of the northern conquerors. When the guardian hand of man was withdrawn, the sea reclaimed its old domain; moles and buttresses were washed away; and promontories, with the proud towers that once crowned their brows, were undermined and tumbled into the deep. Innumerable ruins, heaps of marble, mosaics, and other relics of the past, attest the ancient splendour of the city. The most remarkable are the so-called temples of Mercury, Venus, and Diana, and various buildings which, rightly or wrongly, have been assigned to the more famous of those who are known to have had villas in the town. The *Castello di Baja* was built in the 16th century by Pietro di Toledo. Long. 14° 3′ E., lat. 40° 50′ N.

BAIBURT, a town of Asiatic Turkey, in the pashalic of Erzeroum, and 65 miles W.N.W. from that city. According to Neumann it was an Armenian fortress in the 1st century, and it is identified by Ritter with the *Baiberdon* fortified by Justinian. It was afterwards one of the strongholds of the Genoese, when prosecuting their trade with India. Remains of their fortifications still exist, but in a very dilapidated state, the Russians having blown up the defences in 1829. (See view in Yule's *Marco Polo*, vol. i.) Population of town about 6000.

BAÏF, Jean Antoine de, poet of the French Renaissance and member of the Pleiad, was the natural son of Lazare de Baïf and an Italian girl. He was born in 1532 at Venice, where his father was residing as French ambassador. Thanks, perhaps, to the surroundings of his childhood, he

grew up a fanatic for the fine arts, and surpassed in zeal all the leaders of the Renaissance in France. Besides writing an immense number of short poems of an amorous or congratulatory kind, he translated or paraphrased various pieces from Bion, Moschus, Theocritus, Anacreon, Catullus, and Martial. He resided in Paris, enjoyed the continued favour of the court, and founded the Académie Royale de Musique; his house became famous for the charming concerts which he gave, entertainments at which Charles IX. and Henry III. frequently flattered him with their presence. He was a dear friend of Ronsard and the other members of the Pleiad. His works were published in 4 thick volumes, entitled *Amours, Jeux, Passetemps, et Poëmes* (1571–74), containing, among much that is now hardly readable, some pieces of infinite grace and delicacy. He died in 1589 or 1591. His father, Lazare de Baïf, published a translation of the *Electra* of Sophocles in 1537, and afterwards a version of the *Hecuba*, was an elegant versifier in Latin, and is commended by Joachim du Bellay as having introduced certain valuable words into the French language.

BAIKAL (*i.e.*, *Baïakhal*, or Abundant Water), a great fresh-water lake of Siberia, in the government of Irkutsk, 397 miles in length from S.W. to N.E., and from 13 to 54 miles in breadth, with an area of about 12,500 square miles. This vast reservoir is situated 1360 feet above the level of the sea, in the midst of steep mountain ranges, that often rise sheer from the water's edge in lofty walls of syenite, gneiss, or conglomerate, while elsewhere their sloping flanks are thickly clad with dark forests of coniferous trees. The lake is fed by several rivers,—the Upper Angara, the Selenga, which descends from the basin of Lake Kossogol, the Barguzin, and others; while the only visible outlet is by the Lower Angara, a tributary of the Yenisei. The water is excellent, and is extremely clear, so that the bottom can be seen at the depth of 8 fathoms. The depth of the lake varies from 22 to upwards of 300 fathoms. It yields abundance of salmon, and there is a profitable fishery of seals on its shores during the whole summer. The climate is extremely severe; and the lake, which is frozen over from November to May, is almost perpetually swept by the wind. It facilitates, however, the Russian trade with China, and that between Irkutsk and Dauria. It is navigated by the Russians in summer, and in winter they cross it on the ice. Europeans embarked on its waters for the first time in 1643. Steam-vessels were introduced in 1846, and the passage across is made in about eight hours. Several hot springs and mineral waters are seen on the margin, and naphtha is sometimes found floating on the surface. The lake is between 51° 20′ and 55° 30′ N. lat., and 103° and 110° E. long. The island of Olkhon, near its north shore, is 32 miles long and nearly 10 broad. This island and the southern borders of the lake are inhabited by Mongolian tribes, while towards the north the Tungooses are to be found in gradually diminishing numbers. (See "Description du lac de Baikal," trad. du russe par M. Klaproth, in *Nouv. Ann. des Voy.* t. xvii. p. 289; Erman's *Siberia*, 1848; Semenoff, *Slovar Ross. Imp.*)

BAIKIE, WILLIAM BALFOUR, M.D., eldest son of Captain John Baikie, R.N., was born at Kirkwall, Orkney, on the 21st August 1824. He studied at Edinburgh, and, on obtaining his degree, joined the royal navy. He early attracted the notice of Sir Roderick Murchison, through whom he was appointed surgeon and naturalist to the Niger Expedition of 1854. The death of the senior officer occurring at Fernando Po, Dr Baikie succeeded to the command. The results of the voyage are given in his own and other narratives. Ascending the river about 250 miles beyond the point reached by former explorers, the little steamer *Pleiad* returned and reached the mouth after a voyage of 118 days without the loss of a single man. The second expedition started in March 1857. After two years passed in exploring, the navigating vessel was wrecked in passing through some of the rapids of the river, and Dr Baikie was unable longer to keep his party together. All returned home but himself; no way daunted, he determined single-handed to carry out the purposes of the expedition. Landing from a small boat with one or two native followers at the confluence of the Quorra and Benue, he here chose the old model farm ground as the base of his future operations—a spot memorable from the disasters of the exploring party of 1841. After purchasing the site, and concluding a treaty with the native chief, he proceeded to clear the ground, build houses, form enclosures, and pave the way for a future city. Numbers flocked to him from all parts round, and in his settlement were representatives of almost all the tribes of Central Africa. To the motley commonwealth thus formed he acted not merely as ruler, but also as physician, teacher, and priest. Before five years he had opened up the navigation of the Niger, made roads, and established a market, to which the native produce was brought for sale and barter. He had also collected vocabularies of nearly fifty African dialects, and translated portions of the Bible and prayer-book into Housa. Once only during his residence had he to employ armed force against the surrounding tribes. He died on his way home, at Sierra Leone, in November 1863, aged thirty-nine years. An appropriate monument has been erected to his memory within the nave of the ancient cathedral of St Magnus.

BAIL (*Ballium*) is used in common law for the freeing or setting at liberty of one arrested or imprisoned upon any action, either civil or criminal, on surety taken for his appearance at a certain day and place.

BAILEN, a town of Spain, in the province of Jaen, 24 miles N.N.W. of Jaen. It seems to correspond to the ancient Bæcula, where Scipio gained signal victories over Hasdrubal, 209 B.C., and over Mago and Masinissa, 206 B.C. (Polyb., x. 38, xi. 20; Liv., xxvii. 18–20, xxviii. 13). In the neighbourhood also, in 1212, was fought the great battle of Navas de Tolosa, where Alphonso VIII. is said to have left 200,000 Moors dead on the field, with the loss of only 25 Christians. Here again, on the 23d of July 1808, the French general Dupont, after a bloody contest of several days, signed the capitulation of Bailen, by which 17,000 men were delivered up to the Spaniards as prisoners of war. This disaster was the first great blow to the French arms in the Peninsula. There is nothing remarkable about the town, except the ruins of a castle, formerly belonging to the counts of Benavente, and now the property of the Osuna family. Glass and tiles are manufactured, and the weaving of cloth and pressing of olives are carried on. Population, 7831. (Madoz, *Diccionario*; Ukert, vol. x. p. 379.)

BAILEY, or BAILY, NATHANAEL or NATHAN, an eminent English philologist and lexicographer, whose *Etymological English Dictionary*, published apparently in 1721, was a great improvement on all previous vocabularies, and really formed the basis of Johnson's great work. It is still worthy of being consulted for information with regard to the change of signification in certain words, and to the date at which others were introduced into the language. Bailey had a school at Stepney, near London, and was the author of *Dictionarium Domesticum* and several other educational works. He died in 1742.

BAILEY, SAMUEL, an able writer on philosophical and literary subjects, was born at Sheffield in 1791. His father carried on a large general business in that town, and for some years the son devoted himself to mercantile pur-

suits. It was not long, however, before he gave up this occupation, and, having a competent fortune, withdrew from all business concerns, with the exception of the Sheffield Banking Company, of which he was chairman for many years. Although an ardent Liberal of most advanced views, he took little or no active part in political affairs. On two occasions, at the earnest solicitation of his numerous friends and admirers, he stood for Sheffield, but without success. The "Bentham of Hallamshire," as he has been called, was of too retiring a disposition, and had too much of the philosophical politician about him to win the admiration or suffrages of an ordinary body of electors. His life is for the most part a history of his numerous and varied publications, and his name is known to a very limited circle. The intimation of his sudden death on the 18th January 1870, with the subsequent notice of his munificent gift of £90,000 to his native town, excited some curiosity and interest, which, however, quickly died away. This is not quite as it should be. Bailey has certainly given to the world no work of first-rate importance, but there are few authors of modern times who have written more elegantly and clearly, or with more originality of treatment, on the various problems of psychology and political science. His first work, *Essays on the Formation and Publication of Opinions*, published anonymously in 1821 (2d ed. 1826, 3d ed. 1837), a thoughtful, practical, and clearly written treatise, has attracted a greater share of public attention and favour than any of his other writings. A sequel to it appeared in 1829, *Essays on the Pursuit of Truth, on the Progress of Knowledge, and on the Fundamental Principle of all Evidence and Expectation* (2d ed.1844). Intermediate between these two were *Questions on Political Economy, Politics, Morals, &c.*, 1823, and a *Critical Dissertation on the Nature, Measure, and Causes of Value*, directed against the opinions of Ricardo and his school. His next publications were also on economic or political subjects, *Rationale of Political Representation*, 1835, and *Money and its Vicissitudes*, 1837 ; about the same time also appeared some of his pamphlets, *Discussion of Parliamentary Reform, Right of Primogeniture Examined, Defence of Joint-Stock Banks.* Bailey seems then to have turned his attention almost entirely to speculative philosophy. In 1842 appeared his *Review of Berkeley's Theory of Vision*, an acute and able work, which called forth rejoinders from J. S. Mill in the *Westminster Review* (reprinted in *Dissertations*), and from Ferrier in *Blackwood* (reprinted in *Lectures and Remains*, ii.) Bailey replied to his critics in *A Letter to a Philosopher, &c.*, 1843. In 1851 he published one of his best works, *Theory of Reasoning* (2d ed. 1852), a thoughtful discussion of the nature of inference, and an able criticism of the functions and value of the syllogism. In 1852 he published *Discourses on Various Subjects* ; and finally summed up his philosophic views in the *Letters on the Philosophy of the Human Mind* (three series, 1855, 1858, 1863), which is at once the most considerable and the most valuable of his contributions to mental science. Bailey had not entirely given himself up to abstract studies ; in 1845 he had ventured on poetical composition. *Maro*, a poem in four cantos (85 pp., Longmans), contains a somewhat lively description of the mental state of young poet who printed 1000 copies of his first poem, of which only 10 were sold. He had also been a diligent student of Shakespeare, and his last literary work was the treatise, in two volumes, *On the Received Text of Shakespeare's Dramatic Writings and its Improvement.* It must be confessed that many of the emendations suggested by him are more fantastic than felicitous.

The *Letters* contain, in clear and lively language, a very fresh discussion of many of the principal problems in philosophy, or rather in psychology. Bailey can hardly be classed as belonging either to the strictly empirical or to the idealist school, but his general tendency is towards the former The following are the most interesting points in his work :—(1.) In regard to method, he founds psychology entirely on introspection ; critical study of one's own consciousness is, according to him, the only means of obtaining materials for philosophy. He thus, to a certain extent, agrees with the Scotch school, but he differs from them in rejecting altogether the doctrine of mental faculties. What have been designated faculties are, upon his view, merely classified facts or phenomena of consciousness. He criticises very severely the habitual use of figurative or metaphorical language in describing mental operations. (2.) His doctrine of perception, which is, in brief, that "the perception of external things through the organs of sense is a direct mental act or phenomenon of consciousness not susceptible of being resolved into anything else," and the reality of which can be neither proved nor disproved, is not worked out in detail, but is supported by elaborate and sometimes subtle criticisms of all other theories. Upon this point Bailey's remarks are deserving of attention. (3.) With regard to general and abstract ideas and general propositions, his opinions are those of the empirical school, but his analysis frequently puts the matter in a new light, and brings forward points of novelty. (4.) In the theory of morals Bailey is an advocate of Utilitarianism, and works out with great skill the steps in the formation of the "complex" mental facts involved in the recognition of duty, obligation, right. His handling of the moral sentiments (*Letters*, iii. 193–258) is one of the best specimens of his general style of psychological analysis.

BAILLET, Adrien, a French writer and critic, was born in June 1649, at the village of Neuville, near Beauvais, in Picardy, and died in January 1706. His parents could only afford to send him to a small school in the village, but he picked up some Latin from the friars of a neighbouring convent, who brought him under the notice of the bishop of Beauvais. By his kindness Baillet received a thorough education at the theological seminary, and was afterwards appointed to a post as teacher in the school of Beauvais. In 1676 he took orders, and was presented to a small vicarage. His duties interfering too much with his studies, he accepted in 1680 the appointment of librarian to M. de Lamoignon, advocate-general to the parliament of Paris, of whose library he made a *Catalogue Raisonné in* thirty-five volumes folio, all written with his own hand. The remainder of his life was spent in incessant, unremitting labour ; so keen was his devotion to study that he scarcely allowed himself even natural rest. In the list of his numerous works the following are among the most conspicuous :—1. *Histoire de Holland depuis* 1609 *jusqu' à* 1690, 4 tom. 12mo, a continuation of *Grotius*, and published under the name of Neuville. 2. *Les Vies des Saints*, 3 tom. fol. 3. *Des Satires personelles, traité historique et critique de celles qui portent le titre d'Anti*, 2 tom. 12mo. 4. *Vie de Descartes*, 2 tom. 4to. 5. *Jugemens des Savants sur les principaux Ouvrages des Auteurs*, 9 tom. 12mo. The last is the most celebrated and useful of all the works of this learned and indefatigable writer. The edition in seven volumes quarto, published in 1722 by M. de la Monnoye, contains the *Anti-Baillet* of M. Menage, besides notes ; but the edition published at Amsterdam in 1725 is more esteemed.

BAILLEUL, an ancient town of France, in the department of Nord, near the Belgian frontier, situated on a rising ground to the north of the River Lys. It was formerly a place of great strength, and is now a busy industrial town, with manufactures of lace, thread, black soap, pottery, woollen stuffs and ribbons, brandy, leather, and cheese. Population, 12,896. Lat. 50° 45′ N., long. 2° 44′ E.

BAILLIE, Joanna, poet and dramatist, was born at the manse of Bothwell, on the banks of the Clyde (Scotland), in 1762. At an early period of her life she removed with her sister Agnes to London, where their brother, the celebrated Dr Matthew Baillie, was settled. The two sisters were left a small competence by their uncle, Dr William Hunter, and took up their residence at Hampstead, on the outskirts of London, where they passed the remainder of their lives. Miss Baillie died on the 23d Feb. 1851, at the advanced age of 89, her faculties remaining unimpaired to the last. Her gentleness and sweetness of disposition made her a universal favourite, and her little cottage at Hampstead was the centre of a brilliant literary society. Miss Baillie had received an excellent education, and probably cultivated very early her faculty of poetical composition, but it was not till 1798 that she published the first volume of her *Plays on the Passions*. Her design, founded on a careful study of the nature of dramatic poetry, was to illustrate each of the deepest and strongest passions of the human mind, such as Hate, Jealousy, Fear, Love, by a tragedy and a comedy, in each of which should be exhibited the actions of an individual under the influence of these passions. The success of the first volume was very considerable, and a second edition was soon called for. A second volume followed in 1802, a third in 1812, and three more in 1836. Some miscellaneous dramas were published in 1804, and the *Family Legend* appeared in 1810. Miss Baillie herself intended her plays not for the closet but for the stage. The *Family Legend*, brought out at Edinburgh under the enthusiastic patronage of Sir Walter Scott, had a brief though brilliant success; *De Monfort* had a short run in London, mainly through the acting of Kemble and Mrs Siddons; *Henriquez* and *The Separation* were coldly received. The popular verdict has thus been given against the dramas as good stage plays, and the almost universal decision of readers has confirmed this judgment. With very few exceptions, they are unsuited for stage exhibition. Not only is there a flaw in the fundamental idea, that, viz., of an individual who is the embodiment of a single passion, but there is a want of incident, and a narrowness, consequent upon the attention being too much directed on a single point, that present insuperable obstacles to their success as acting pieces. The plot is generally well constructed, but the very consciousness of aim with which it is wrought out gives to the whole a morbid and unnatural aspect; there is rarely, if ever, any progress in the play; the whole is apparent from the outset, and the action never heightens the spectators' interest. It must be confessed, also, that Miss Baillie had no very adequate notion of what is required in a stage drama, and that her experience was too limited. This is apparent in her comedies, which are very inferior productions. In short, her want of success is a clear proof of the impracticability of that analytic or psychological method, which she expounds and defends in her preliminary dissertations. The plays, however, are admirably adapted for reading; they show remarkable powers of analysis and acute observation, and are written in a pure and vigorous style, rising occasionally into strains of high poetic feeling and expression. The best of the tragedies are undoubtedly *Henriquez*, *The Separation*, *De Monfort*, and *Count Basil*, the first of which might perhaps be made into a good acting play. Miss Baillie's reputation does not rest entirely on her dramas: she is the authoress of some poetical pieces and songs of great beauty, and in all probability great portion of her fame will be found to rest on these minor works. The best of them are the *Lines to Agnes Baillie on her Birthday*, *The Kitten*, *To a Child*, and some of her adaptations of Scotch songs, such as *Woo'd and Married an' a'*. Scattered throughout the dramas are also some lively and beautiful songs, such, *e.g.*, as the *Chough and the Crow* in *Orra*, the lover's song in the *Phantom*, beginning—

> "I've seen the moon gleam through the cave,
> And minute drops like diamonds glancing."

And the sailor's song—

> "O swiftly glides the bonny boat
> Just parted from the shore."

(See Joanna Baillie's *Dramatic and Poetical Works*, Lond. 1851, 1 vol.)

BAILLIE, Dr Matthew, anatomist and physician, was born in the manse of Shotts, Lanarkshire, in 1761. He came of a highly gifted family: his father, the Rev. James Baillie, was successively clergyman of the parishes of Shotts, Bothwell, and Hamilton, in Lanarkshire, and afterwards professor of divinity in the university of Glasgow; his mother was Dorothea, sister of the celebrated William and John Hunter; and his sister Joanna was the poet. Dr Baillie was for several years a student in the university of Glasgow, where he heard the lectures of Dr Reid on moral philosophy. His professional career was determined by the advice of his uncle, Dr William Hunter, who undertook to superintend his education. On his father's death he obtained an exhibition to Balliol College, Oxford, where he remained a year before removing to London. His studies were there carried on under the personal direction of his uncle, and after two years he began to be associated with Dr Hunter in his anatomical lectures as an assistant and demonstrator, visiting Oxford occasionally, so as to keep the terms necessary for the degree of bachelor of medicine. Dr Hunter, at his death, bequeathed the use of his magnificent collections to his nephew, together with the lecture-rooms in Windmill Street, an annuity of £100 a year, and a small family estate in Scotland. The last was resigned by Baillie to his other uncle, Dr John Hunter, whom he considered as the natural heir. Within two years after Dr Hunter's death his nephew became the principal teacher in that celebrated school of anatomy; and in 1787, although only a bachelor of medicine, he was appointed physician to St George's Hospital. In 1789 he married Sophia, daughter of the eminent accoucheur Dr Denman, a connection favourable to his practice. In 1795 he published his *Morbid Anatomy*, a work which was speedily translated into French, Italian, and German, into the last by the anatomist Sömmering. After this he had the honour of being enrolled a doctor of medicine of Oxford, and Fellow of the Royal College of Physicians. As a practising physician he was universally respected, and his decease, which took place on the 23d of September 1823, in the 63d year of his age, was sincerely regretted.

The second edition of the *Morbid Anatomy* appeared in 1797; and two years afterwards it was illustrated by a 4to volume of engravings, with descriptions of the plates. His *Anatomical Lectures and Medical Observations* were printed privately after his death. The *Works*, 2 vols. 8vo, edited, with a biographical sketch, by Mr Wardrop, contain only the *Morbid Anatomy* and miscellaneous medical papers.

BAILLIE, Robert, a prominent Scotch Presbyterian of the 17th century, was born at Glasgow 1602. He graduated in 1620 at the university of that town, and then applied himself to the study of divinity. In 1631, after he had been ordained and had acted for some years as regent in the university, he was appointed to the living of Kilwinning in Ayrshire. The church disputes of the century were just beginning, and Baillie was naturally drawn into them. In 1638 he was a member of the famous Glasgow Assembly, and soon after he accompanied Leslie and the Scotch army as chaplain or preacher. In 1642 he was made professor of divinity at Glasgow, and in the following year was selected as one of the five Scotch

clergymen who were sent to the great Westminster Assembly. In 1649 he was one of the commissioners sent to Holland for the purpose of inviting Charles II. to Scotland, and of settling the terms of his admission to the government. He continued to take an active part in all the minor disputes of the church, and in 1661, after the ejection of Gillespie, he was made principal of the Glasgow University. He died in August of the following year,—his death being probably hastened by his mortification at the apparently firm establishment of Episcopacy in Scotland. Baillie was a man of learning and ability; his views were not extreme, and he played but a secondary part in the stirring events of the time. His *Letters*, by which he is now chiefly remembered, are of considerable historical importance, and give a very lively picture of the period. A complete memoir and a full notice of all his writings will be found in Dr Laing's edition of the *Letters and Journals of Robert Baillie*, Bannatyne Club, 3 vols., Edinburgh, 1841–42.

BAILLY, Jean Sylvain, a French astronomer and orator, was born at Paris on the 15th September 1736. He was originally intended for the profession of a painter; his own inclinations, however, tended strongly towards literary pursuits, and it is said that at a very early age he had completed two tragedies. But his acquaintance and friendship with the celebrated mathematician Lacaille, and perhaps the example of his brilliant young contemporary Clairaut, finally decided the direction of his studies, which were then entirely devoted to science and scientific investigation. The first of his labours was a calculation of the comet which appeared in the year 1759. In 1763 he was admitted a member of the Academy of Sciences; and in the same year he published a reduction of the observations made by Lacaille in 1760 and 1761 on the zodiacal stars, a compilation of great labour and utility. In 1764 he competed for the prize offered by the Academy for a dissertation on the theory of Jupiter's satellites. Lagrange, who was a complete master of the most powerful analysis, was the successful competitor; but Bailly's memoir, which was published in an expanded form in 1766, showed great ability, and at once established the author's reputation as a physical astronomer. He followed up his dissertation in 1771 with an able and important memoir on the *Light of the Satellites*, in which he expounded some novel and elegant methods of observation.

His attention, meantime, was not solely devoted to abstract science; he was equally distinguished for eloquence and brilliancy of style. His *Éloges* on Corneille, Leibnitz, Molière, and others, were universally admired. In 1773 he was proposed as a candidate for the secretaryship of the Academy of Sciences, and was supported by Buffon; the influence of D'Alembert, however, secured the appointment of the famous Condorcet. In 1784 Bailly was made secretary of the French Academy, and in the following year he was admitted to the Academy of Inscriptions and Belles Lettres. This was the only instance, from the time of Fontenelle, of any writer being at the same time a member of all the three academies.

In the year 1775 he published the first volume of his most extensive work, *History of Astronomy*, which contained the history from its origin down to the foundation of the Alexandrian school. This was followed by three volumes on *Modern Astronomy*, published between 1776 and 1783. The work is of little or no historical value, but it is admirably written, and added greatly to the author's reputation as a master of narrative exposition. In 1787 he completed the history by a volume on Indian and Oriental astronomy, which shows considerable erudition, but is not founded on a complete knowledge of the Indian records, and is highly fantastic in its speculations.

The quiet course of Bailly's life, hitherto devoted to literature and science, was now broken in upon by that great convulsion, the French Revolution, of which he was one of the first and most zealous promoters. In the part which he acted, he has had the singular good fortune to be well spoken of by opposite factions, and has never been charged either with want of integrity or with selfish designs. When the states-general of France were assembled in 1789, he was elected a deputy to the *tiers-état*, of which he was afterwards chosen president; and when the national assembly had been constituted, he continued in the chair, and officiated as president at the time the king's proclamation was issued ordering that body to disperse. During the struggle which took place between the national assembly and the court, Bailly was amongst the most forward in asserting those popular rights which were then new in France; and it was he who dictated the famous oath to the members of the *tiers-état*, by which they pledged themselves "to resist tyrants and tyranny, and never to separate till they had obtained a free constitution." On the 14th of July following, the day on which the Bastille was stormed and taken by the people, he was by universal consent appointed mayor of Paris. In this high office he is allowed to have acted with great integrity, courage, and moderation, and to have discharged its arduous and sometimes perilous duties in a highly honourable manner, and during its course he was instrumental in promoting the various measures by which the popular party at length prevailed over that of the court; for which, as well as for his conduct in other respects, he obtained a high degree of popularity. But the multitude, newly unshackled from the fetters of despotism, greedy of novelty, fired with enthusiastic and unsettled notions of freedom, and daily panting for change, would brook no opposition to their wild schemes. Bailly, who probably saw too late the general disposition of the people to anarchy, still wished the laws to be respected, and hoped by the vigorous enforcement of them to restore and maintain tranquillity. He ordered some deputies from the military insurgents of Nancy to be arrested, and firmly opposed the rash proceedings of Marat and Hebert; he ceased to be a member of the Jacobin club; and he exerted himself strongly to persuade the populace to permit the king and royal family to depart to St Cloud. By these measures, which were very distasteful to the fickle and infuriated people, he lost their confidence and favour; and his popularity was finally destroyed by his conduct on the occasion of the tumultuous meeting of the populace on the 17th of July 1791, to demand the abolition of monarchy; for, when called on by the national assembly to disperse the mob, who had assaulted the soldiery, he ordered the latter to fire, by which means 40 persons were killed and above 100 wounded. Finding himself after this an object of hatred and suspicion to the people, whom he had faithfully served, he resigned his office at the dissolution of the constituent assembly in the end of the year 1791, and retired to Nantes. From there he wrote to Laplace, who was residing at Melun, and proposed, if it were safe, to join him. Laplace, finding that a detachment of revolutionary troops had been ordered to Melun, advised Bailly not to venture, but his advice was neglected. The ex-mayor was recognised by one of the soldiers, arrested, and thrown into prison. Arraigned on 10th November 1793 before a sanguinary tribunal, he was on the 11th condemned to death as a conspirator, and executed the day following, near the spot where he had given the order for the military to fire on the people. He met his death with the greatest calmness and courage.

Several works written by Bailly, and found in manuscript, have been published since his death; particularly an *Essay on Fables and their History*, and *Memoirs of a Witness of the Revolution*,

which come down to October 1789. Notices of his life are given in the *Éloges* by St Just, Lalande, and Lacretelle; also in Arago, *Notices Biographiques*, vol. ii.

BAILY, Edward Hodges, a distinguished sculptor, was born at Bristol, 10th March 1788, and died at London, 22d May 1867. His father, who was a ship-carver of great repute, destined him for a commercial life, but even at school the boy showed his natural taste and remarkable talents by producing numerous wax models and busts of his schoolfellows, and afterwards, when placed in a mercantile house, still carried on his favourite employment. Two Homeric studies, executed for a friend, were shown to Flaxman, who bestowed on them such high commendation, that in 1807 Baily came to London and placed himself as a pupil under the great sculptor. In 1811 he gained the Academy gold medal for a model of *Hercules restoring Alcestis to Admetus*, and soon after exhibited *Apollo discharging his arrows against the Greeks*, and *Hercules casting Lichas into the sea*. In 1821 he was elected R.A., and exhibited one of his best pieces, *Eve*. He was for many years engaged in lucrative employment as modeller for Messrs Rundell & Co. and Messrs Storr & Mortimer. He was also entrusted with the carving of the bas-reliefs on the south side of the Marble Arch at Hyde Park. Besides numerous busts and statues, such as those of Nelson on the Monument, of Earl Grey, of Lord Mansfield, and others, his finest pieces are, *Eve at the Fountain*, *Eve listening to the Voice*, *Maternal Affection*, *Girl preparing for the Bath*, and the *Graces*.

BAILY, Francis, an English astronomer, was born in Berkshire in the year 1774, and for many years carried on business as a stockbroker in London. While amassing a large fortune by his business, he applied the profound mathematical knowledge for which he was distinguished to the doctrine of probabilities, and published several interesting works on that subject, as, *Tables for the Purchasing and Renewing of Leases*, *The Doctrine of Interest and Annuities*, *The Doctrine of Annuities and Assurances*, &c. In 1820 he was one of the original and most active promoters of the Astronomical Society; and on his retirement from business in 1825, he entered with the utmost energy upon the cultivation of astronomy and the kindred sciences. He gave the *Nautical Almanac* its present form and introduced other improvements; he took an active part in the investigation of the effects of the atmosphere on pendulum experiments; he aided in the repetition of the experiment of Cavendish on the specific gravity of the earth; he superintended the publication of the Astronomical Society's catalogue of the fixed stars; and the revision of the annual catalogues in the 13th volume of the Society's *Memoirs* was entirely his work. On his recommendation the British Association undertook the republication of the *Histoire Céleste* of Lalande, combined with Lacaille's catalogue, which together contain no less than 57,000 stars; and there is reason to believe that he took an important part in the investigation of the course of the tidal wave in the Atlantic. His *Account of the Rev. John Flamsteed, First Astronomer-Royal*, 1835, a work of great ability and research, excited much discussion from the disclosures it made relative to the character of Sir Isaac Newton. Baily was extremely patient and methodical, and these qualities enabled him to effect, in the last twenty years of his career, a greater number of researches than most other philosophers have accomplished during a whole lifetime. He died August 30, 1844.

BAINBRIDGE, Dr John, physician and astronomer, was born at Ashby-de-la-Zouche, in Leicestershire, in the year 1582. He taught a grammar school for some years, and practised physic, employing his leisure hours in astronomy, which was his favourite study. After removing to London he was admitted a Fellow of the College of Physicians, and gained considerable reputation by his description of the comet in 1618. The next year Sir Henry Savile appointed Bainbridge his first professor of astronomy at Oxford; and the masters and fellows of Merton College made him first junior, and then superior, reader of Linacre's lecture. He died in 1643. His published works are—1. *An Astronomical Description of the late Comet*, Lond. 1619. 2. *Procli Sphæra*, 1620. 3. *Canicularia; a Treatise concerning the Canicular Days*, Oxford, 1648. Several of his unpublished writings exist in manuscript in the library of Trinity College, Dublin.

BAINES, Edward, for many years proprietor and editor of the *Leeds Mercury*, and M.P. for Leeds from 1834 to 1841, was born in 1774 at Walton-le-Dale, a village distant a little way from Preston, in Lancashire. He was educated at the grammar schools of Hawkshead and Preston, and at the age of sixteen was apprenticed to a printer in the latter town. After remaining there four years and a half he removed to Leeds, finished his apprenticeship, and at once started in business for himself. He was always a most assiduous student, and quickly became known as a man of great practical shrewdness and ability, who took a keen interest in political and social movements. His liberal opinions in politics led him to sympathise with the dissenting party in church affairs, and it was not long before he joined the body of Independents. In 1801 the assistance of friends among the members of that party enabled him to purchase the copyright of the *Leeds Mercury*. Provincial newspapers did not at that time possess much influence; the editorial province was not extended to the composition of what are now called leading articles, and the system of reporting was defective. In both respects Baines made a complete change in the *Mercury*. The ability of his political articles gradually caused the paper to be looked upon as the organ of Liberal opinion in Leeds, and it contributed not a little to the spread of sound doctrines on practical questions in the north of England. At the same time his watchful care secured the efficiency of the minor departments. Baines soon began to take a more prominent part in politics; he was an ardent advocate of parliamentary reform, and it was mainly by his influence that Macaulay was returned for Leeds in 1832. In 1834, when a vacancy was caused by Macaulay's acceptance of an Indian appointment, Baines was proposed as a candidate, and was returned after a sharp contest. He was re-elected in 1835 and 1837, but was obliged to resign from ill-health in 1841. He was noted in Parliament as a judicious supporter of the Liberal party, but with independent views. He strongly advocated the separation of church and state, and opposed Government interference in national education. His letters to Lord John Russell on the latter question (1846) had a powerful influence in determining the action of the Government. He died in 1848. In the midst of his active life he had found time for literary work. His best-known writings are:—*The History, Directory, and Gazetteer of the County of York; History, Directory, and Gazetteer of the County of Lancaster; History of the County Palatine and Duchy of Lancaster*. He was also the author of a *History of the Wars of Napoleon*, which was continued under the title of *A History of the Reign of George III*. His *Life* (1861) has been written by his son, Edward Baines, jun., for some time editor, and still (1875) one of the proprietors, of the *Leeds Mercury*, and well known by his histories of the cotton and woollen manufactures of Great Britain.

BAINES, Matthew Talbot, eldest son of the above, was born in 1799, and died in 1860. He was educated at Cambridge, and entered the bar. In 1837 he was made

recorder of Hull, and in 1847 was returned to Parliament for that city. His remarkable ability made itself quickly apparent, and in 1848 he became president of the Poor-Law Board. In 1852 he sat for Leeds, and was again appointed president of the Poor-Law Board, which office he held till 1855. In 1856 he was made chancellor of the Duchy of Lancaster, with a seat in the Cabinet.

BAINI, GIUSEPPE, a learned musical critic and composer of church music, was born at Rome in 1775, and died there in 1844. He was instructed in composition by his uncle, Lorenzo Baini, and afterwards by Jannaconi. In 1814 he was appointed musical director to the choir of the pontifical chapel, in which he had for several years been one of the principal bass singers. His compositions were very favourable specimens of the severe ecclesiastical style; one in particular, a *Miserere*, was long performed alternately with the more celebrated work of Allegri in the services of the Sistine chapel during Passion week. Baini held a higher place, however, as a musical critic and historian than as a composer, and his *Life of Palestrina* (*Memorie storico-critiche della vita e delle opere di Giovanni Pierluigi da Palestrina*, 1828) ranks as one of the best works of its class.

BAIRAM, a Turkish or Persian word meaning *feast*, is the name applied to the two great Mahometan festivals. The first of these, called generally, though, according to some authorities, incorrectly, the Greater Bairam, is the day following the Ramadan, or month of fasting. It lasts strictly for only one day, though the common people generally extend it to three, and is a period of great animation and enjoyment. What is called commonly the Lesser Bairam follows the first at an interval of sixty days. It is the feast of sacrifices, at which all Mahometans imitate the offerings of animals which are then being made at Mecca to commemorate Abraham's offering of Isaac. It lasts for four days, and is not of so sacred a character as the first Bairam.

BAIRD, GENERAL SIR DAVID, Bart., was born at Newbyth in Aberdeenshire, in December 1757. He entered the British army in 1773, and was sent to India with the 73d Highlanders in 1779. In the following year he had the misfortune to fall into the hands of Hyder Ali, in the Mysore chief's perfidious attack on a handful of British troops at Perambucum. The prisoners, it is well known, were most barbarously treated. Baird survived his captivity; and on his release, visited his native country, but returned to India in 1791 as a lieutenant-colonel. When Harris marched against Tippoo Sahib, Baird, now a major-general, served under him in that campaign; and when it was resolved to storm Seringapatam, he solicited and obtained the honour of leading the storming party to the breach. He made a daring assault, and was soon a master of the stronghold in which he had long been the prisoner. Through some misconception, Baird seems to have looked upon the temporary appointment of Colonel Wellesley to hold the captured town as permanently superseding him, and on this ground he judged himself to have been treated with injustice and disrespect. He afterwards received the thanks of the British Parliament and of the East India Company for his gallant bearing on that important day, and a pension was offered him by the Company, which he declined, apparently from the hope of receiving the order of the Bath from the Government. General Baird commanded the Indian army which was sent in 1801 to co-operate with Hutchinson in the expulsion of the French from Egypt. He landed at Kosseir, conducted his army to Keneh on the Nile, and thence to Rosetta, where he arrived just as the French were treating for the evacuation of Alexandria. On his return to India in 1802 he was employed against Scindia, but irritated at some neglect he had experienced, he relinquished his command and returned to Europe. In 1804 he was knighted, and in the following year commanded the expedition against the Cape of Good Hope, and captured Cape Town; but here again his usual ill-luck attended him, for he was recalled before he had organised his conquest for having sanctioned the expedition of Sir Home Popham against Buenos Ayres. He served again in 1807 in the expedition against Copenhagen, and in the following year commanded the considerable force which was sent to Spain to co-operate with Sir John Moore. In the battle of Coruña, where, after the death of Moore, he held supreme command, a grape-shot shattered his left arm, so that it had to be amputated at the shoulder-joint. He again obtained the thanks of Parliament for his gallant services, and was rewarded with the decoration of the order of the Bath, and the rank of a baronet. Sir David married Miss Campbell Preston, a Perthshire heiress, in 1810. In 1820 he was appointed commander-in-chief in Ireland; but the post does not appear to have been suitable for him, and he was removed in 1821. From that period he no more appeared in public life. He died on the 18th August 1829. (See Hook's *Life of Sir David Baird.*)

BAIREUTH, or BAYREUTH, the capital of the circle of Upper Franconia, in Bavaria, is pleasantly situated in a valley on the left bank of the Red Maine, 40 miles N.N.E. of Nuremberg. It is well built, with broad, regular, and well-paved streets, and is partially surrounded by old walls. The river is crossed here by two bridges. Most of the buildings are of comparatively modern date, the city having suffered severely from the Hussites in 1430, and from a conflagration in 1621. Among the more important are—the old castle, erected in 1454, the new castle, built in 1753, the opera-house, one of the finest in Germany, the gymnasium, founded in 1664, the riding school, and the barracks. Among the ecclesiastical buildings, the *Stadtkirche*, dating from 1439, and containing the monuments of the margraves of Baireuth, is the most important; and there are also a handsome synagogue, a public library, theatre, hospital, and an orphan and a lunatic asylum. In 1841, a monument, by Schwanthaler, was erected here to Jean Paul Richter, who spent the last twenty years of his life in the city, and has left some beautiful descriptions of the neighbourhood in his *Siebenkäs*. His house was in Friedrichsstrasse. Baireuth is a railway junction, and has an active trade, chiefly in grain and horses. It manufactures woollen, linen, and cotton goods, leather, delft and other earthenware, and tobacco, and has also several breweries and distilleries. About half a league distant is the village of St George, noted for its marble works; and about two miles to the E. is the Hermitage, a fanciful building, erected in the early part of the last century, with gardens containing terraces, statues, and fountains. Baireuth has been chosen by Richard Wagner as the scene of his musical festivals, and a theatre is being erected for his special use. Population, 17,841. Baireuth was formerly the capital of a principality of the same name, which was annexed in 1791 to the kingdom of Prussia. In 1807 it was ceded by Prussia to France, which kept possession of it till 1810, when it was transferred to Bavaria.

BAJA, a market-town of Hungary, in the county of Bacs, on the left bank of the Danube, 90 miles S. of Pesth. It was burned down in 1807, but has since been well built. It carries on a considerable trade in grain and pigs, and its four annual markets are largely attended. The Roman Catholics, the Greek Church, and the Jews have each a place of worship in the town, which also possesses a gymnasium, and a castle belonging to the Grassalkovich family. Population, 18,110.

BAJAZET I., sultan of the Turks, commenced to reign in 1389, and died in 1403. The well-known story of the iron cage, in which this monarch was said to have been carried about by his conqueror Timur, has no authority, and probably originated in a mistake as to the word for a *litter*, in which Bajazet was carried.

BAJAZET II., son of Mahomet II., succeeded his father as sultan in 1481, and died in 1512. See CONSTANTINOPLE and TURKEY.

BAJUS, or DE BAY, MICHAEL, a celebrated theologian, was born at Melin in Hainaut in 1513. He distinguished himself highly during his course of study at Louvain, and was quickly promoted to a professorship in the college of that town. In 1549 he took his doctor's degree, and two years later he was appointed regius professor of divinity. On account of his eminence in theological learning he was selected by the king of Spain to go to the great council at Trent, in the proceedings of which he took a prominent part. His studies having been chiefly directed to Augustine, with whose works he was very familiar, Bajus found that his doctrines on the fundamental points of freewill, predestination, grace, and the sacraments, were in direct opposition to the scholastic theology recognised as orthodox by the powerful body of the Jesuits. Eighteen propositions, said to be gathered from the works of Bajus and his colleague Hessels, were condemned by the Sorbonne, and a more extensive collection of seventy-six were censured by Pope Pius V. in 1567. This censure, which did not press very heavily on Bajus, who was not indeed mentioned as holding the condemned doctrines, was confirmed by a bull of Gregory XIII. in 1580. Bajus, who was a man of meek and mild temper, quietly made such submission as was requisite under the circumstances, continued to hold his professorship, and even advanced to the dignity of chancellor of the university. He died in 1589, in the 77th year of his age. His principal works have been published in a collected form at Cologne, 1696, 1 vol. 4to, in 2 parts; some large treatises have not been published. The doctrines for which Bajus was censured, and the discussions arising with regard to them, are interesting in connection with the history of Jansenism, for Jansen did little more than reproduce the Augustinianism of Bajus.

BAJZA, JOSEPH, a distinguished Hungarian poet and critic, was born at Szücsi in 1804. His earliest contributions were made to Kisfaludy's *Aurora*, a literary paper of which he was editor from 1830 to 1837. He also wrote largely in the *Kritische Blätter*, the *Athenæum*, and the *Figyelmezö*, or *Observer*. His criticisms on dramatic art were considered the best of these miscellaneous writings. In 1830 he published translations of some foreign dramas, *Ausländische Bühne*, and in 1835 a collection of his own poems. In 1837 he was made director of the newly established national theatre at Pesth. He then, for some years, devoted himself to historical writing, and published in succession the *Historical Library* (*Törtereti Könyvtár*), 6 vols. 1843–45; the *Modern Plutarch* (*Uj Plutarch*), 1845–47; and the *Universal History* (*Világtörétet*), 1847. These works are to some extent translations from German authors. In 1847 Bajza edited the journal of the opposition, *Ellenör*, at Leipsic, and in March 1848 Kossuth made him editor of his paper, *Kossuth Hirlapja*. In 1850 he was attacked with brain disease, and died in 1858.

BÁKARGANJ, a district of British India in the Dacca division, under the Lieutenant-Governor of Bengal, situated between 23° 14′ 27″ and 21° 48′ N. lat., and 89° 55′ 10″ and 91° 4′ 50″ E. long. It is bounded on the N. by the districts of Dacca and Farídpur, from which it is separated by the Padmá and Mainákátíkhál; on the E. by the Meghná and Sháhbázpur rivers, and by the Bay of Bengal, which separates it from Noákhálí and Tipperah; on the S. by the Bay of Bengal; and on the W. by Jessor and Farídpur districts. Area, 4935 square miles; population, 2,377,433. The general aspect of the district is that of a flat even country, dotted with clusters of bamboos and betel-nut trees, and intersected by a perfect network of dark-coloured and sluggish streams. There is not a hill or hillock in the whole district, but it derives a certain picturesque beauty from its wide expanses of cultivation, and the greenness and freshness of the vegetation. This is especially conspicuous in the rains, but at no time of the year does the district present a dried or burnt-up appearance. The villages, which are always walled round by groves of bamboos and betel-nut palms, have often a very striking appearance; and Bákarganj has many beauties of detail which strike a traveller in passing through the country. The level of the country is low, forming as it does a part of the great Gangetic delta; and the rivers, streams, and water-courses are so numerous that it is very difficult to travel except by boat at any season of the year. Every natural hollow is full of water, around the margin of which long grasses, reeds, and other aquatic plants grow in the greatest profusion, often making it difficult to say where the land ends and where the water begins. Towards the north-west the country is very marshy, and nothing is to be seen for miles but tracts of unreclaimed swamps and rice lands, with a few huts scattered here and there, and raised on mounds of earth. In the south of the district, along the sea face of the Bay of Bengal, lie the forest tracts of the Sundarbans, the habitation of tigers, leopards, and other wild beasts.

The principal rivers of the district are the Meghná, the Ariál Khán, and the Haringhátá or Baleswar, with their numerous offshoots. The Meghná represents the accumulated waters of the Brahmaputra and Ganges. It flows along the eastern boundary of the district in a southerly direction for about 100 miles, till it debouches into the Bay of Bengal. During the latter part of its course this noble river expands into a large estuary containing many islands, the principal of which is that of Dakshín Sháhbázpur. The Ariál Khán, a branch of the Ganges, enters the district from the north, and flows generally in a south-easterly direction till it falls into the estuary of the Meghná. The main channel of the Ariál Khán is about 1700 yards in width in the dry season, and from 2000 to 3000 yards in the rains. It receives a number of tributaries, sends off several offshoots, and is navigable throughout the year by native cargo boats of the largest size. The Haringhátá, Baleswar, Madhumati, and Garai, are various local names for the same river in different parts of its course, and represent another great offshoot of the Ganges. It enters Bákarganj near the north-west corner of the district, whence it forms its western boundary, and runs south, but with great windings in its upper reaches, till it crosses the Sundarbans, and finally falls into the Bay of Bengal by a large and deep estuary, capable of receiving merchant ships of considerable burden. In the whole of its course through the district the river is navigable by native boats of large tonnage, and by large sea-going ships as high up as Morrellganj, in the neighbouring district of Jessor. Among its many tributaries in Bákarganj the most important is the Kachá, itself a considerable stream and navigable by large boats all the year round, which flows in a southerly direction for 20 miles, when it falls into the Baleswar. Other rivers of minor importance are the Barisál, Bíshkhálí, Nihálganj, Khairábád, Ghágar, Kumár, &c. All the rivers in the district are subject to tidal action from the Meghná on the north, and from the Bay of Bengal on the south, and nearly all of them are navigable at high tide by country boats of all sizes. The rise of the tide is very considerable in the estuary of the Meghná, and many of the creeks and water-courses in the island of Dakshín Sháhbázpur, which are almost dry at ebb tide, contain 18 or 19 feet of water at the flood. A very strong "bore" or tidal wave runs up the estuary of the Meghná at spring tides, and a singular sound like thunder, known as the "Bárisal Guns," is often heard far out at sea about the time it is coming in. There are numerous marshes in the district, of great size and depth, and abounding in fish. The following peculiarity of some of them is quoted from Colonel Gastrell's *Geographical and Statistical Report of the District* (1868):—"In some of the swamps, especially in those of Bákarganj, the surface growth of aquatic plants, mixed with drift weeds,

grasses, and rice stalks, increases annually, and in process of time a crust is formed capable of supporting human beings, and on which rice is cultivated. Small floating patches are thus formed, and the natives assert that in very strong blowing weather these are sometimes carried from one side of the swamp to the other, and are a cause of great dispute. A Government official, whose duties often took him to these swamps, mentioned that the first time he found himself on ground of this kind, being totally unaware of its nature, he was greatly alarmed at feeling, as he thought, the earth moving beneath him; and still more astonished when, on seeking information from the inhabitants, he was told 'it was only the tide coming in.' The owners of these floating fields make holes through them, and catch the fish which are immediately attracted by the light."

The census of 1872 disclosed a population of 2,377,433 souls in Bákarganj district, spread over 4935 square miles, inhabiting 4269 villages and 321,657 houses; persons per square mile, 482; per village, 557; per house, 7·4. The Mahometans are the largest section of the population, and number 1,540,965, or 64·8 per cent. of the total inhabitants; Hindus, 827,393, or 34·8 per cent.; Buddhists, 4049 or ·2 per cent.; Christians, 4852, or ·2 per cent.; and persons of unspecified religion, 174 souls. The Musalmáns of Bákarganj are among the worst of their creed, steeped in ignorance and prejudice, easily excited to violence and murder, very litigious, and grossly immoral. The Faráizís or Puritan sect of Mahometans are exceedingly numerous in the district. The Buddhist population consists of Maghs or the people of Arákán, who first settled in Bákarganj about seventy years ago, and have made themselves very useful in the clearing of the Sundarbans. A gipsy-like tribe called the Bebájiás are rather numerous in this district. They principally live in boats, travelling from place to place, profess Muhammadanism, and gain their subsistence by wood-cutting in the Sundarbans, fishing, fortune-telling, and trading in trinkets. The Christian community of Bákarganj owes its origin to the Roman Catholic monastery at Bandel near Calcutta, and to the Protestant (Baptist) missionaries at Serampur. The principal native converts come from the Hindu low-caste Chandáls, &c., who subsist by cultivation.

Barisál, the headquarters station, situated on the west bank of the Barisál river, in 21° 41′ 40″ N. lat., and 90° 24′ 30″ E. long., is the only town containing upwards of 5000 inhabitants. In 1872 its population amounted to 7684 souls; municipal income, £1019, 18s.; municipal expenditure, £1006, 2s.; incidence of taxation, 2s. 7¾d. per head. There are also three other municipal towns—(1.) Nalchití, a large trading village; principal exports, rice and paddy; imports, salt, tobacco, oil, and sugar; (2.) Jhálakátí or Mahárájganj, a large timber market, also trading in rice, paddy, and salt; (3.) Daulat Khán, the principal village in the island of Dakshín Sháhbázpur; exports, betel-nut. A number of small trading villages exist throughout the district, and each locality has its periodical fairs for purposes of traffic. The material condition of the people is good. Every inhabitant is a small landholder, and cultivates sufficient rice and other necessaries for the support of his family. Owing to this reason, hired labour is very scarce, and during the harvest season, when the few available labourers are sought for by the landholders, the price of labour rises to 1s. per diem. The average cost of living to a labouring man is about 6s. per month. Except in the larger villages, the dwellings of the people are very isolated. The inhabitants seldom congregate together into hamlets, but each man builds his homestead on the highest spot on his own land without any reference to his neighbours. Rice is the great crop of the district, and three harvests are obtained annually—the *áman*, or winter rice; *áus*, or autumn crop; and *boro*, or spring rice. The former yields the finest grain, and is the staple crop of the district. It is sown at the setting in of the rains in April or May, transplanted from the beginning of June to the middle of August, and reaped in November or December. About 100 varieties of the *áman* rice are cultivated in the district. The *áus* crop is sown in the early part of the hot weather, and reaped in August. Upwards of 20 varieties of this rice are produced. The *boro* or spring rice is of a coarse description, largely used by the poorer classes, and is cultivated to a considerable extent in the alluvial river accretions, and on other low-lying grounds. It is sown broadcast in December, and reaped in April or May. Bákarganj exports its rice chiefly to Calcutta. The average yield of rice land here is from 17½ to 22 cwt. per acre. Other crops—*khesárí* (*Lathyrus sativus*), *musuri* (*Cicer lens*), *sarishá* or mustard, rape-seed, linseed, jute, sugar-cane, betel-nut, &c. Manufactures—pottery, coarse cloth, oil, fine mats, and molasses. The district has only five small roads, but its rivers afford ample means of communication.

Like all other districts of Bengal, Bákarganj has steadily increased in prosperity since its administration passed into the hands of English officers, and especially of late years, since the country has been directly under the Crown. From the time of the acquisition of Bengal by the British in 1765 up to the end of 1817, Bákarganj formed a part of the Dacca district. It was then formed into a separate collectorship, with the object of encouraging enterprising persons to cultivate its immense tracts of waste lands. In 1818 the net revenue of the district amounted to £96,438, and the net civil expenditure to £13,647. Two years later (1820) the net district revenue had slightly decreased to £95,709, while the net expenditure on civil administration had increased to £16,659. During the next forty years both revenue and expenditure rapidly increased, and in 1860–61 the net revenue of the district amounted to £150,305, and the net civil expenditure to £32,584. In 1870–71 the total net revenue was £203,445, and net civil expenditure, £44,902. The land revenue of Bákarganj is settled in perpetuity with the *zamíndárs*. In 1872 the district contained 4729 estates, held by 5960 proprietors, who were assessed at a total revenue of £143,156. In 1871 the machinery for protecting the district consisted of 583 men of the regular police of all ranks, maintained at a total cost of £11,186. Attached to the regular police is a river patrol consisting of five boats, and manned by a crew of 35 men. The village watch or rural police consisted in 1871 of 5135 men, maintained at a cost of £18,486, paid by the landholders and villagers, each village watchman having besides a small plot of ground rent free. A municipal police of 53 men was also maintained in the towns and large villages, at a total cost of £403, 14s., defrayed out of municipal receipts. Education is in a very backward state in Bákarganj, owing to the inhabitants being almost wholly composed of petty husbandmen, the majority of whom are Mahometans of the most bigoted tenets. In 1856–57 the district contained 5 schools, attended by 482 pupils, and maintained at a total cost of £595, 13s. In 1871–72 there were 78 Government and aided schools, attended by 3713 pupils, and maintained at a total cost of £3767, 12s., the total cost to the state being £1232, 10s. This is exclusive of private schools uninspected by the education department. The census report of 1872 returned the total number of schools (Government and private) at 512, attended by a total of 7299 pupils. Barisál town contains a Government school, which is the largest in Eastern Bengal, and financially the most successful; the cost to Government for its 355 pupils in 1872 being only £31, 12s. Bákarganj district is divided into 5 magisterial sub-divisions, viz., Barisál, Dakshín Sháhbázpur, Mádárípur, Pirozpur, and Patuákhálí, comprising 18 police circles or *thánás*, and 54 fiscal divisions or *parganás*. The climate of Bákarganj is one of the healthiest in Eastern Bengal, owing to the strong south-west monsoon, which comes up directly from the Bay of Bengal, and keeps the atmosphere cool; but the heavy rain-fall and consequent humidity of the atmosphere, combined with the use of bad water, are fruitful sources of disease. The average annual temperature varies from 78° to 85°. The thermometer ranges from 62° to 98°. The endemic diseases of Bákar-

ganj are fevers of the intermittent, remittent, and continued types, attributable to the extreme dampness and malarious nature of the district. Cholera is always present, the number of cases increasing in the hot season and the beginning of the cold weather. Smallpox occasionally makes its appearance in an epidemic form,—frequently caused by inoculation, which is carried on to a great extent in Bákarganj by the native medical practitioners.

BAKER, Henry, a distinguished naturalist, was born in Fleet Street, London, in 1698. At the age of fifteen he was apprenticed to a bookseller, with whom he remained for seven years. He then became clerk to Mr Forster, attorney, whose deaf and dumb daughter he instructed carefully, and with such success that for a time he devoted himself to the training of persons similarly afflicted. During this period of his life he published several poems, and married Sophia, youngest daughter of the famous Daniel Defoe, who bore him two sons, both of whom he survived. In 1740 he was elected fellow of the Society of Antiquaries and of the Royal Society. He contributed many memoirs to the *Transactions* of the latter society, and in 1744 received the Copley gold medal for microscopical experiments on the crystallisation and configuration of saline particles. Mr Baker died at his apartments in the Strand on the 25th of November 1774. Besides his numerous memoirs in the *Philosophical Transactions*, he published two valuable treatises on the microscope: *The Microscope made Easy*, London, 1743, and *Employment for the Microscope*, 1753. Another well-known work is his philosophical poem, *The Universe*, which has passed through several editions. Mr Baker's memory is perpetuated by the Bakerian Lecture of the Royal Society, for the foundation of which he left by will the sum of £100.

BAKER, Sir Richard, author of the *Chronicle of the Kings of England*, was born at Sissinghurst, in Kent, about the year 1568. He was educated at Oxford, took the degree of Master of Arts, and in 1603 received the honour of knighthood. In 1620 he was made high sheriff of Oxfordshire; but having engaged to pay some debts of his wife's family, he was reduced to poverty, and obliged to betake himself for shelter to the Fleet prison, where he died, February 18, 1645. During his confinement he composed numerous works, historical, poetical, and miscellaneous. Amongst these are *Meditations and Disquisitions on the Lord's Prayer; Meditations, &c., on several of the Psalms of David; Meditations and Prayers upon the Seven Days of the Week; Cato Variegatus*, or *Cato's Moral Distichs; Theatrum Triumphans*, or *Theatrum Redivivum*, being a reply to Prynne's *Histriomastix*, &c. His principal work, the *Chronicle of the Kings of England*, inexact and uncritical, but written in a pleasant and readable style, quickly acquired a high reputation. It was continued to 1658 by Edward Phillips, Milton's nephew, and has passed through many editions.

BAKER, Thomas, a learned antiquary, descended from an ancient family distinguished by its loyalty, was born at Crook in 1656. He was educated at the free school at Durham, and proceeded thence, in 1674, to St John's College, Cambridge, where he afterwards obtained a fellowship. Lord Crewe, bishop of Durham, collated him to the rectory of Long-Newton in his diocese, in 1687, and further intended to give him that of Sedgefield, with a golden prebend, had not Baker incurred his displeasure for refusing to read James II.'s Declaration of Indulgence. The bishop who disgraced him for this refusal, and who was afterwards specially excepted from William's Act of Indemnity, took the oaths to that king, and kept his bishopric till his death. Baker, on the other hand, though he had opposed James, refused to take the oaths to William; he resigned Long-Newton on the 1st of August 1690, and retired to St John's, in which he was protected till the 20th of January 1716–17, when he and one-and-twenty others were deprived of their fellowships. After the passing of the Registering Act in 1723, he could not be prevailed on to comply with its requirements by registering his annuity of £40, although that annuity, left him by his father, with £20 per annum from his elder brother's collieries, was now his whole subsistence. He retained a lively sense of the injuries he had suffered; and inscribed himself in all his own books, as well as in those which he gave to the college library, *socius ejectus*, and in some *rector ejectus*. He continued to reside in the college as commoner-master till his death on the 2d of July 1740. The whole of his valuable books and manuscripts he bequeathed to the university. The only works he published were, *Reflections on Learning, showing the Insufficiency thereof in its several particulars, in order to evince the usefulness and necessity of Revelation*, Lond. 1709–10, and the preface to Bishop Fisher's *Funeral Sermon for Margaret, Countess of Richmond and Derby*, 1708,—both without his name. His valuable manuscript collections relative to the history and antiquities of the university of Cambridge, amounting to thirty-nine volumes in folio and three in quarto, are divided between the British Museum and the public library at Cambridge,—the former possessing twenty-three volumes, the latter sixteen in folio and three in quarto. The life of Baker has been written by Robert Masters, 8vo, 1784, and by Horace Walpole, in the quarto edition of his works.

BAKEWELL, a market-town in Derbyshire, on the River Wye, 152 miles from London. Its fine old church contains monuments of the families of Vernon and Manners. The inhabitants are supported by the working of the coal, lead, and zinc mines, and the stone and marble quarries in the neighbourhood. There is also a large cotton manufactory in the town established by Arkwright. Bakewell is remarkable for a chalybeate spring, frequented by invalids. It has a free school of ancient date, a literary and scientific institution, and a museum. About four miles distant is Chatsworth House, the seat of the duke of Devonshire. Population in 1871, 2283.

BAKHCHISARAI (Turkish, *the Garden Palace*), a town of Russia in the government of Taurus, situated in a narrow gorge on the banks of a small stream called the Chiryuk-Su, about 10 miles S.S.W. of Simpheropol. Of unknown origin, it became towards the close of the 15th century the residence of the Tatar khans; and its chief objects of interest are the remains of its splendour under the Tatar dynasty. The principal building, the palace, or *Khan-Serai*, was originally erected in 1519 by Abdul-Sahal-Gerai, and was restored at Potemkin's command by the architect Elson for the reception of Catherine. Not far off is a cemetery, which contains the tombs of many of the khans. There are, besides three or four churches and a synagogue, no fewer than thirty-five mosques, of which the most important was founded in the early part of the 18th century. The population still consists for the most part of Tatars, Catherine II. in 1783 having granted them the exclusive right of habitation in the city. The remainder consists of Russians, Greeks, Armenians, and Jews. Bakhchisarai is a place of considerable industry, manufacturing red and yellow morocco, sheepskin cloaks, agricultural implements, sabres, and other cutlery, and forming an important depôt for the corn, flax, fruits, tobacco, and other produce of the whole surrounding district. In the neighbourhood is Chufut-Kali (or Jews' city), the chief seat of the Karaitic Jews of the Crimea, situated on lofty and, except on one side, inaccessible cliffs. Population, 10,528.

BAKHMUT, a town of Russia in the government of Ekaterinoslav, near the river from which it derives its name. It owed its origin in the latter half of the 17th century to the discovery of salt-springs, which ceased, however, to be utilised in 1782. Its present importance is chiefly due to the extensive coal-deposits in the vicinity. Population, 16,791.

BAKING. The art of baking consists in heating anything in an oven or fire so as to harden it, and in this sense the term is used when applied to the manufacture of bread, porcelain, pottery, and bricks. It is also applied to certain modes of dressing or cooking animal food; thus we speak of baked meats, pies, &c. In the present article the baking of flour or meal for use as human food will alone be treated of.

The origin of baking, as of most arts of primary importance, precedes the period of history, and is involved in the obscurity of the early ages of the human race. Excavations conducted on the site of some of the numerous lake dwellings of Switzerland have resulted in the discovery of abundant evidence that the art of making bread was practised by our prehistoric ancestors as early as the Stone Period. Not only have stones for grinding meal and baking bread been discovered, but bread itself in large quantities has been disinterred, preserved by being carbonised in the fires which frequently destroyed the pile-dwellings of the primitive inhabitants of the world. At Robenhausen, Meisskomer discovered 8 ℔ of bread, a weight which would correspond with about 40 ℔ of newly-baked bread. At Wangen there has been discovered "actual baked bread or cake made of the crushed corn, precisely similar to that found about the same time by Mr Meisskomer at Robenhausen. Of course, it has been burned or charred, and thus these interesting specimens have been preserved to the present day. The form of these cakes is somewhat round, and about an inch to an inch and a half in diameter. The dough did not consist of meal, but of grains of corn more or less crushed. In some specimens the halves of grains of barley are plainly discernible. The under side of these cakes is sometimes flat, sometimes concave, and there appears no doubt that the mass of dough was baked by being laid on hot stones and covered over with glowing ashes."—(Keller's *Lake Dwellings*, Lee's Translation, p. 63.)

The very early mention of bread in written history further bears out the great antiquity of the art of baking. Bread is first specifically mentioned in Genesis xviii. 5, when Abraham, wishing to entertain the three angels on the plains of Mamre, offered to "fetch a morsel of bread;" and the operation of baking is immediately thereafter alluded to in the instructions to Sarah to "make ready quickly three measures of fine meal, knead it, and make cakes upon the hearth." At the same time, when, in the city of Sodom, Lot entertained two angels, "he made them a feast, and did bake unleavened bread, and they did eat" (Genesis xix. 3). It may be inferred from the mention of unleavened bread that, in those patriarchal times, the two great classes of bread were known and used. At a period little later the art of baking was carried to high perfection in Egypt, which then took the lead in the arts of civilised life. The Egyptians baked cakes and loaves of many varieties and shapes, in which they employed several kinds of flour, and they flavoured their bread with various aromatic ingredients. The chief baker of Pharaoh, who was in prison along with Joseph, doubtless pursued his craft in its essential features in the same way as bakers do at the present day.

From ancient Egypt excellence in the art of baking travelled with the march of civilisation into Greece, and the allusions to bread in the works of classic authors are very numerous. In *The Deipnosophists* of Athenæus mention is made of no less than sixty-two varieties of bread as known among the ancient Greeks, and minute descriptions of many of them are given. We learn from Pliny (*Nat. Hist.*, xviii. 28) that professional bakers were first introduced into Rome at the close of the war with Perseus, king of Macedon. By the practical Romans the baking trade was formed into a kind of incorporation or guild, with special privileges and immunities attached to the calling. Public bakeries were distributed throughout the city, to which slaves were assigned for performing the heavier and more disagreeable tasks connected with the occupation. Grain was delivered into public granaries by enrolled *Saccarii*, and it was distributed to the bakers by a corporation called the *Catabolenses*. No separate mills for grinding corn then existed, the grain being pounded and sifted in the bakeries, and hence the Roman bakers were known as *Pistores*. A special magistrate was appointed to take cognisance of every matter connected with the management of public bakeries.

The calling of the baker during the Middle Ages was considered to be one so closely affecting the interests of the public that it was put under strict regulation and supervision, and these special restrictions continued to affect the trade down to very recent times. In England, an Act of Parliament was passed in 1266 for regulating the price of bread by a public assize, and that system continued in operation till 1822 in the case of the city of London, and till 1836 for the rest of the country. The price of bread was determined by adding a certain sum to the price of every quarter of flour, in name of the baker's expenses and profit; and for the sum so arrived at tradesmen were required to bake and sell eighty quartern loaves, or a like proportion of other sizes, which it was reckoned each quarter of flour ought to yield. The following table exhibits the assize price of bread in London in 1814:—

Price of Flour in Shillings.	Price of Quartern Loaf.		Price of 8-℔ Loaf.		Price of 4-℔ Loaf.		Price of 2-℔ Loaf.		Price of 1-℔ Loaf.	
	s.	d.	s.	d.	s.	d.	s.	d.	s.	d.
30	0	6½	1	0	0	6	0	3	0	1½
35	0	7¼	1	1¼	0	6¾	0	3¼	0	1¾
40	0	8	1	2¾	0	7¼	0	3¾	0	1¾
45	0	8¾	1	4	0	8	0	4	0	2
50	0	9½	1	5½	0	8¾	0	4½	0	2¼
60	0	11	1	8¼	0	10¼	0	5	0	2½
70	1	0½	1	11	0	11½	0	5¾	0	3
80	1	2	2	1¾	1	1	0	6½	0	3¼
90	1	3½	2	4½	1	2¼	0	7¼	0	3½
100	1	5	2	7¼	1	3¼	0	7¾	0	4

The art of making bread made its way northwards very slowly; and even at present, in the northern countries of Europe and Asia, loaves of bread are seldom used except by the higher classes of inhabitants. In Sweden, for example, rolls are frequently seen in the towns, but loaves rarely. Towards the end of 1812 the captain of an English packet ordered a Gothenburg baker to bake for him a quantity of bread, to the value of £1 sterling. The baker was confounded at so large an order, and refused to comply till the captain gave him security that he would carry off and pay for the loaves, declaring that he could never dispose of so great a quantity of bread in Gothenburg if it were left upon his hands. In the country part of Sweden no bread is made but rye-cakes, nearly as hard as flint, which are only baked twice a year. About a century ago loaf-bread was almost as rare in the rural districts of Scotland, *barley bannocks* and *oaten cakes* then constituting the universal substitutes among almost all ranks. In many parts of England it is the custom for private families to bake their own bread. This is particularly the case in

Kent, and in some parts of Lancashire. In the year 1804 the town of Manchester, with a population of 90,000 persons, did not contain a single public baker. Bakers in Great Britain are now placed under the provisions of "The Bakehouses' Regulation Act, 1863" (26 and 27 Vict. cap. 40), a statute passed after a searching inquiry into the condition of bakehouses in London and of the persons employed in them. By this Act no young person under the age of 18 is permitted to work in a bakehouse between the hours of 9 P.M. and 5 A.M., and special enactments provide for securing the cleanliness and ventilation of bakehouses, and for the regulation of sleeping apartments connected with them.

Bread-stuffs. As compared with wheat-flour all other materials used for making bread are of comparative insignificance. Oat cakes still form a staple article of food in many rural districts of Scotland, and are occasionally used in other countries. They are made by mixing up oatmeal, warm water, and salt, sometimes with the addition of butter or fat, into a very stiff paste, and kneading this out into a thin cake, which is first fired on a hot plate or "girdle," and finished in front of an open fire. Scones of barley-flour, sweet and tough, were formerly largely used in Scotland, but have now given place to a similar preparation of wheaten flour. Rye bread, both fermented and unfermented, is largely consumed by the inhabitants of the northern parts of Europe in the poor and backward districts. Cakes of maize meal, baked like oat cakes, are consumed in some parts of the United States. The meal of various species of millet is used in Southern Europe to form bread; and in India and China, durra (*Sorghum vulgare*) and other cereal grains are baked for food. Of non-cereal flours, the principal used for bread-making is buckwheat, *Fagopyrum esculentum*, extensively employed in Russia and Holland. The flour of pease, beans, and other leguminous seeds, are also baked into cakes; and cassava cakes are made from the meal of the tapioca plant, *Jatropha Manihot*, in South America. Excepting rye, none of these substances is used for making vesiculated or fermented bread.

The grain of wheat consists of an outer husk or covering, an embryo or germ, and a central mass of farinaceous material. The outer husk is composed of several distinct layers of ligneous tissue, closely adhering to the seed, and very hard in texture. In grinding, this is detached in scales, and constitutes the chief proportion of the bran. The inner portion of the envelope is softer, and contains an active nitrogenous principle, termed cerealin, and is besides rich in fat and salts. This portion goes with the pollard or parings in the dressing of wheat flour. Towards the centre of the grain the substance becomes whiter in colour and more friable in texture, so that, in grinding, the finest flour in consistence is always the whitest in appearance. By agriculturists several hundred varieties of wheat and a number of distinct species are recognised; but in commerce the grain is distinguished as white and red, or as hard and soft wheats. There is a considerable range of difference in the proportions of their proximate constituents, hard wheats as a rule being much more nitrogenous than the soft varieties; and similarly, wheats grown in hot climates are also usually richest in nitrogen. The following analyses of two typical varieties of wheat are taken from Payen's tables, water being neglected:—

	Hard Wheat. Taganrog.	Soft Wheat. Touzelle.
Nitrogenous matter	20·00	12·65
Starch	63·80	74·51
Dextrin	8·00	6·05
Cellulose	3·10	2·80
Fatty matter	2·25	1·87
Mineral matter	2·85	2·12

When wheat is ground it is sifted or dressed into a series of mill products, ranging from fine flour to bran, according to the size of the ground particles. The divisions vary in different mills and localities; but the accompanying table —the result of an elaborate series of experiments by Messrs Lawes and Gilbert—may be regarded as a standard of the relative proportions of mill products:—

Mean Yield of Flour, Bran, &c., in 100 parts Meal.

	Wheat of 1846. 7 Cases.	Wheat of 1847 19 Cases.	Wheat of 1848. 2 Cases.	Mean of the 28 Cases.
1. Wire 1	44·0	35·7	47·4	41·1
2. Wire 2	17·9	16·4	23·9	18·6
3. Wire 3	8·7	13·3	2·0	9·2
Amounts of 1, 2, and 3 together	69·3	70·2	73·3	70·2
4. Tails	4·9	5·8	2·1	5·3
5. Fine Sharps or Middlings	10·2	8·7	4·5	8·8
6. Coarse Sharps	3·5	3·3	3·6	3·4
7. Fine Pollard	3·9	1·8	2·6	2·4
8. Coarse Pollard	4·4	7·2	7·9	6·5
9. Long Bran	3·5	2·5	5·9	3·0

The tails and fine sharps are generally passed through the mill a second time, bringing up the yield of flour to about 80 per cent. of the entire grain. As an example of mill products in practice, the following table is copied from the actual mill receipts of a Scotch miller. The quantity dealt with represents [illegible]5 quarters of wheat, weighing 63¾ ℔ per bushel, in all 578 st. 11 ℔. The yield was—

	St.	℔
Fine Flour	414	0
Odd and Second Flour	23	13
Parings (Sharps and Pollards)	36	12
Bran and Shellings	92	0
Waste	11	0

The composition of flour and bran given in the understated table is the mean result of a series of fourteen analyses by Peligot:—

	Flour.	Bran.
Water	14·0	10·30
Fatty matters	1·2	2·82
Nitrogenous substances insoluble in water (gluten)	12·8	10·84
,, ,, soluble ,, (albumen)	1·8	1·64
Non-nitrogenous soluble substances—dextrin, sugar	7·2	5·80
Starch	59·7	22·62
Cellulose	1·7	43·98
Salts	1·6	2·52

It is a disputed point whether dextrin or sugar exists in flour of the best quality; but the action of heat and moisture in the baking process quickly transforms a portion of the starch into the soluble condition. In flour of inferior quality a large percentage of dextrin is usually found—a circumstance very detrimental to its bread-making qualities. A table of the percentage of gluten, obtained by Messrs Lawes and Gilbert from a large number of flours, shows a variation from 8·9 to 14·9 per cent. This gluten itself (the insoluble nitrogenous substance in flour) is a compound body, composed of three or four distinct substances; but its physical conditions of elasticity, tenacity, and colour are of much greater importance to the baker than either its chemical constitution or its amount.

The varieties of wheaten bread are divisible into two great classes—*Unvesiculated* and *Vesiculated* Bread. Under the first head are included such products of the art as are fired or baked without first being raised or rendered spongy by the development of carbonic acid gas within the mass, either by fermentation or otherwise. Vesiculated bread is produced when carbonic acid is either developed in or introduced into the dough, so as to permeate the mass with an infinite number of minute cavities, which render the product light and spongiform.

Unvesiculated Bread.—The simplest form of bread, and the rudest baking, are seen in the Australian "Damper," a cake made from dough composed of flour, salt, and water, baked in the dying embers of a wood fire. The dough is laid on a flat stone, covered with a tin plate, and the hot ashes heaped around and over it, care being taken not to expose it to a heat of more than 212° Fahr. Pass-over cakes, scones, and "bannocks" are prepared from a similar dough, and fired on hot plates or in ovens, and form

Biscuits. an agreeable and nutritious food. When such dough is exposed to a high heat, so that the resulting cake is hard, dry, and resonant, biscuits (*bis cuit*, twice baked) are formed.

Biscuit Manufacture.—Biscuit making is a branch of trade distinct from ordinary baking, conducted under different conditions, and requiring machinery and processes peculiar to itself. Biscuits are made by a rapid and continuous process; they can be preserved a long time, and in proportion to their price they occupy little space, so that it is practicable to sell them in markets remote from the place of manufacture. The manufacture of biscuits is now conducted on a very large scale, ingenious and complicated machinery is employed in the various processes, and a large export trade in biscuits has grown up. The firm of Messrs Carr & Co., of Carlisle, was the first to originate the manufacture, and that firm still possesses one of the largest and best-appointed establishments. To the partners of this firm we are indebted for much information as to the processes employed in this modern industry.

The general arrangements of a ship-biscuit factory are shown in the sectional view, fig. 1. The flour stored on the

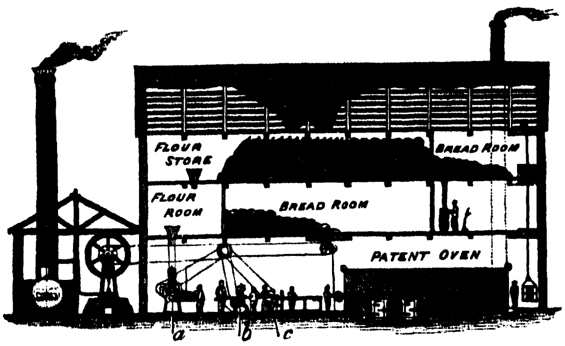


Fig. 1.—Sectional view of Ship-Biscuit Factory.

upper floor is passed down through a shoot to the flour-room, where it is sifted to free it from knots or lumps. In the making of plain water or ship biscuits, the flour is shot directly down into the mixer *a*, on the ground floor, in quantities usually of one bag at a time, to which the requisite quantity of water, regulated by a gauge-glass, is added. The mixer is a cylindrical vessel of cast-iron, in which a series of knives or arms is kept revolving on a central axis. The revolution of these knives is sufficient to incorporate the flour and water thoroughly into a very stiff dough in about seven minutes. From the mixer the dough is delivered on a table in large amorphous masses, and it is next carried forward to the brake machine *b*. The brake consists of two heavy iron rollers, having generally a reciprocating motion, between which the dough is passed backwards and forwards several times till it is rolled out into a plate or sheet of uniform thickness and consistency. The sheet of prepared dough is next carried forward to the cutting and panning machine *c*, a highly complex and ingenious apparatus, the principle of which is shown in fig. 2. In this machine the dough is first passed between a pair of gauge-rollers *a*, graduated to secure a sheet of any desired uniform thickness, from which it is received on an endless sheet of felt *b*. On this web the sheet of dough is carried forward by intermittent motion to a punching apparatus *c*, in which moulds or cutting edges of the

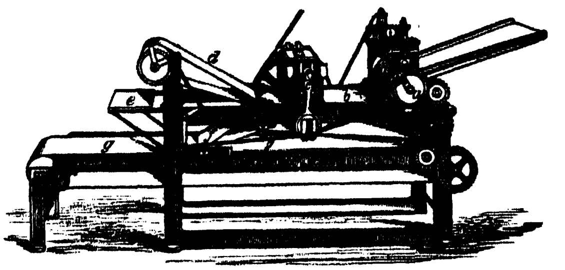

Fig. 2.—Cutting and Panning Machine.

size and form of biscuit desired are arranged. Here the biscuits are cut out, the scrap being caught on a web *d*, and carried upward till it falls over in a box or trough on the table *e*, from which it is returned to the brake machine. The biscuits are carried down the web *f*, and fall into tin trays, which are fed in at *g* by a boy, and move forward at the same rate the biscuit web travels, so that they are ready for being immediately placed on the travelling stage of the patent oven. The processes are so arranged that the oven carries forward the biscuits as quickly as they are delivered by the cutting machine, and in some cases the ovens are fed direct from the cutting and panning apparatus by automatic machinery. The patent travelling ovens are constructed from 30 to 44 feet long, and fitted with endless webs either of plates or chains. The chain webs are used for baking small and fancy biscuits, such as are placed in trays, and the plates are used for large and plain water biscuits, which are placed by hand on the travelling plates. The rates at which biscuits of different sizes and degrees of richness must traverse the whole length of the oven varies from about five to forty minutes, and the temperature of the oven has also to be modified to suit the various qualities. Both the heat and rate of motion are under easy and adequate control in the patent ovens.

There is an endless variety in the form and composition of plain and fancy biscuits. In the trade list of Messrs Vicars, of Liverpool, the chief manufacturers of biscuit machinery, the names of 128 varieties of cutters are mentioned. In the making of fancy biscuits, milk, eggs, sugar, butter or lard, and flavouring essences are extensively used, and in these cases the proportions of the various ingredients are roughly mingled before being sent down the shoot into the mixer. The richest class of biscuits, the dough for which is necessarily soft, are cut out by hand labour and fired on trays in common ovens. The dough for rout biscuits is placed in a strong metal box or chamber in which a piston is tightly fitted. The piston is moved forward by a screw, and it pushes the dough through a series of holes or dies. The dough is received on a sliding board and is cut into proper lengths by a knife. Cracknels are made without either milk or water being used to mix the dough, eggs alone being employed for this purpose. Certain proportions of butter, sugar, and sesquicarbonate of ammonia are added to the mixture of flour and eggs, and the dough is baked in the usual way. The cracknels, when cut out, are thrown into a boiler of boiling water, and in about two minutes they float to the top. They are then fished out and thrown into cold water, and then drained on cloths, panned, and fired in an ordinary oven at a high heat. In the firing, the ammonic carbonate, being very volatile, is driven off, and the cracknel thus assumes its spongy structure. Many other varieties of biscuits are rendered light and spongiform by the use of the sesquicarbonate of ammonia, or of carbonate of soda, in conjunction with sour milk. In the firing of biscuits, not only the moisture of the dough is driven off, but a certain pro-

portion of the water held by the flour in its apparently dry state, so that from 10 ℔ of flour only about 9 ℔ of water biscuits are obtained. The composition of plain biscuit is given by Dr Parkes as follows:—

Water	8 to 12	Sugar	1·9
Nitrogenous substances	15	Fat	1·3
Dextrin	3·8	Starch	72 to 75

Loaf-bread. VESICULATED BREAD.—Under this head is included such bread as is rendered spongiform in structure by the action of carbonic acid within the dough, and which is not baked hard and dry as in the case of biscuits. It includes ordinary loaf bread, pan loaves, French or Paris loaves, cottage loaves, bricks, rolls, buns, and many varieties of fancy bread distinguished by local names and minor differences of form and composition. Vesiculated bread is made in three different ways:—

1*st*, By the development of carbonic acid within the dough through fermentation of the flour. This is the ordinary and principal method of bread-making.

2*d*, By mixing the dough with water previously aerated with carbonic acid. The aerated bread made under the patent of the late Dr Dauglish is thus manufactured.

3*d*, By the disengagement of carbonic acid from chemical agents introduced into the dough. Dodson's patent unfermented bread comes under this head, and the "baking powders" and "yeast powders" extensively sold consist generally of carbonate of soda or ammonia and citric or tartaric acid, which evolve carbonic acid in presence of water.

Fermented Bread.—The manufacture of fermented or leavened bread is, as has already been hinted, of very great antiquity, and it is still by the fermentation process that bread is chiefly made. In ancient times leaven was employed to induce fermentation in dough ("a little leaven leaveth the whole lump," Gal. v. 9), and to this day Parisian bakers, who excel all others in the quality of the bread they produce, chiefly use the same ferment. Leaven is simply a portion of dough, put aside from a previous baking, in which the fermentative action has reached an advanced stage of activity. Yeast, however, has been used as a ferment from an early period, and it appears that it was first so employed in France. Pliny says (*Nat. Hist.*, xviii. 12), "Galliæ et Hispaniæ frumento in potum resoluto, spuma ita concreta pro fermento utuntur; qua de causa levior illis quam cæteris panis est." The use of yeast appears to have died out in France, but was revived again towards the end of the 17th century, when its reintroduction was violently opposed by the Faculty of medicine of Paris. Yeast is now used by Parisian bakers for fancy bread and pastry only.

The baking of fermented bread involves three distinct operations, which are technically denominated "setting the sponge," making the dough or kneading, and baking or firing. It will be convenient first to describe these processes as they are conducted in a London bakehouse. The first duty of the baker is to mix a ferment, which consists of a mixture of potatoes, yeast, and flour. The potatoes, in the proportion of 6 ℔ to a sack of flour, are boiled and mashed in a tub, and water is stirred in till the mixture is reduced to a temperature of from 70° to 90° Fahr. About 2½ pints of yeast and 12 ℔ of flour scalded in boiling water are then added, and the whole forming a thin uniform paste is set aside for several hours, during which it undergoes an active fermentation. Setting the sponge consists in mixing the ferment in a large trough with flour and water sufficient to make the whole into a rather stiff paste. The flour used at this stage, when "full sponge" is made, should be about one-half the entire quantity intended to be used in the "batch," and the ingredients have to be thoroughly incorporated by the workman stirring them laboriously together with his arms. The operation occupies from twenty minutes to half an hour, and when ready the sponge is covered over and allowed to rest for several hours according to the temperature at which it is maintained. Generally in from four to five hours the sponge "rises;" fermentation has been going on, and carbonic acid steadily accumulating within the tenacious mass till it has assumed a puffed out appearance. By degrees the sponge gives off the gas in puffs, and the mass begins to collapse, till what was a swollen convex surface assumes a somewhat concave form, the centre being depressed while the sides adhere to the edges of the trough. The workman judges by the amount of collapse the time the sponge is ready to be taken in hand for kneading or making the dough. This process is thus described by an eye-witness:—"The batch consisted of a sack and a half of flour, nearly one-half of which had been used in making the sponge. Two men commenced breaking the sponge at 1.4 P.M. Having poured the water into it, they plunged their arms in and stirred it about until it became of the consistency of thin batter. At 1.10 they began to mix the dry flour with it, immediately upon doing which they were enveloped in a cloud of flour dust, their heads being bent down to within a few inches of the mass they were handling. Flour and pieces of dough were splashed over the trough upon the floor. At 1.12 a third man was added. Their hair, caps, and face powdered thickly with the dust, a thick cloud of which was thrown up with every movement, especially when large masses of dough, as it became a little solid, were taken up in their arms and thrown upon the rest, fresh flour being first strewn between. At 1.15 one of the men became very red and heated. The other two were very pale, and did not show any perspiration. At 1.16 the cutting off of large masses began, as much as two men could lift to place over the adjoining mass. At 1.23 the men began to pound the mass with their fists. At 1.26 one of the pale men, who was also very thin, began to look red and hot. At 1.29, after smoothing the mass down, they began again to pound it with their fists. At 1.30 it was again smoothed over, the sides of the trough scraped, and a little dry flour thrown over it. It was then considered finished."[1] After this laborious process the finished dough is covered over for some time, varying from half an hour to two hours according to the temperature, during which fermentation again begins, and the mass is "proofed." It is then "scaled off," *i.e.*, weighed on scales in pieces of 4 ℔ 4 oz., if 4-℔ loaves are to be made, or half that amount for 2-℔ loaves; and as rapidly as weighed it is "moulded" into the form of the loaf, when it is ready to put into the oven. Flour of good quality will take up about 17 gallons of water in course of the foregoing operations, and before putting into the oven the ingredients of a 4-℔ loaf will be—

	℔	oz.
Flour	3	2
Water	1	1½
Yeast	0	0½
Potatoes	0	1½
Salt	0	0½

A loaf ready for going into the oven has about half the bulk it attains during the process of firing. Batches of cottage and household loaves are packed close side by side on the sole of the oven, the sides of each loaf being rubbed with butter to prevent them from adhering to each other, and they are consequently crusted on the top and bottom only. Pan loaves are baked each in separate tinned pans of the form of the loaf, and Parisian loaves are baked end to end in long tinned pans. The firing of bread in the oven occupies from 1 to 1½ hours, the temperature at the

[1] Tremenheere's *Report on Journeymen Bakers.*

beginning of the process being from 550° to 600° Fahr. The baker can ascertain if the oven is at a proper temperature by throwing a little flour on the sole of the oven, which ought to turn to a light brown colour. Ovens in London are usually built of brick, with a sole only 2½ inches thick; in Scotland stone is used, the sole being from 10 to 12 inches thick, and the oven consequently retains heat much more effectually.

In Scotland the system of using ferments is not generally practised as in London, some of the varieties of yeast or barn being mixed directly with the flour. In some localities the system of setting "quarter sponge" is adopted, in which the sponge originally prepared contains only one-fourth of the flour to be used. To this, after an interval of about twelve hours, more flour and water are added, which brings it up to half sponge, and about two hours thereafter the mass is ready for making the dough. In Paris, where bread-making is carried to the highest perfection, leaven, as has already been mentioned, is the fermenting agent employed. This consists of a portion of dough laid aside from a previous baking in a uniform temperature for seven or eight hours, during which it swells and acquires an alcoholic odour. This, termed "the chief leaven," is taken and worked up with flour and water to a firm paste double its original mass, when it becomes the "first leaven." After an interval of six hours the amount is again doubled, forming the second leaven. The "complete leaven" is formed by doubling the size of the second leaven, and the proportion the complete leaven bears to the finished dough is about one-third in summer and one-half in winter.

Sound flour yields from 90 to 94 4-lb loaves per bag of 280 lb, some "strong" flours giving even a greater quantity of bread. A table of experiments, conducted by Messrs Lawes and Gilbert, gives a mean result of 135·2 of bread from 100 of flour; and in the observations of a large number of English and French authorities quoted by them, the ratio of bread to 100 of flour varied from 127 to 150. The following table gives the mean of 25 analyses of the bread of London bakers by Dr Odling:—

Water	43·43
Organic matter	55·26
Mineral matter or ash	1·30
Percentage of ash in dry bread	2·30
,, nitrogen in new bread	1·26
,, ,, in dry bread	2·22

The bakers' standard of excellence of flour, apart from the question of colour, is the weight of bread it will produce of a proper dryness and texture. The "strength" of flour in this respect appears to depend much more on its condition than on the absolute percentage of its constituents.

Panary Fermentation.—It would be altogether out of place in this paper to refer to the conflicting theories as to the cause of fermentation in organic substances. The so-called panary fermentation in bread-making is a true alcoholic fermention, and whether induced by yeast or leaven the result is precisely the same. The gluten of the flour is the fermenting agent, and it is stirred into activity by contact with a glutinous body already in an active condition, which may be either yeast or leaven. In this condition it exerts a fermentative influence over the sugar which may either have existed previously in flour, or which is at least immediately developed in it by the influence of moisture. The active gluten splits up each molecule of sugar into two of alcohol, two of carbonic acid, and one of water, and consequently an infinite number of minute air bubbles are developed throughout the fermenting mass. The reaction is shown in the following equation: $C_6H_{14}O_7 = 2C_2H_6O + 2CO_2 + H_2O$.

	Carb.	Hyd.	Oxy.	Carb.	Hyd.	Oxy.
1 molecule of Grape Sugar				6	14	7
2 molecules of Alcohol	4	12	2			
2 ,, Carbonic Acid	2	...	4			
1 ,, Water	...	2	1			
				6	14	7

As the evolution of carbonic acid and alcohol proceeds, the sponge gradually swells, the little bubbles coalesce and enlarge, rising through the tenacious mass till the surface is reached, and then the carbonic acid bursts out and the dough begins to fall. This process would go on a considerable time, but the alcoholic fermentation would soon pass into an acetous fermentation and the sponge would become sour. When acetous fermentation ensues, as not unfrequently happens in baking, it may be remedied to some extent by the addition of bicarbonate of soda to the sponge. The late master of the mint, Dr Thomas Graham, was the first to demonstrate the presence of alcohol in fermented dough, and he thus described his experiment:—"To avoid the use of yeast, which might introduce alcohol, a small quantity of flour was kneaded, and allowed to ferment in the usual way to serve as leaven. By means of the leaven a considerable quantity of flour was fermented, and when the fermentation had arrived at the proper point, formed into a loaf. The loaf was carefully enclosed in a distillatory apparatus, and subjected for a considerable time to the baking temperature. Upon examining the distilled liquid, the taste and smell of alcohol were quite perceptible, and by repeatedly rectifying it, a small quantity of alcohol was obtained, of strength sufficient to burn and to unite gunpowder by its combustion. The experiment was frequently repeated, and in different bakings the amount of the spirit obtained of the above strength was found to vary from 0·3 to 1 per cent. of the flour employed." Although the temperature of the oven drives off that amount of the spirit, fermented bread is yet found to retain a proportion of alcohol, as much as from 0·221 to 0·401 per cent. having been found in different specimens of baked bread. Speaking in 1858, Dr Odling estimated the amount of alcohol thrown out into the atmosphere from the bread baked in London as equal to 300,000 gallons of spirits annually. Many years ago a patent was secured by a Mr Hicks for collecting and condensing the alcoholic fumes from bakers' ovens, and a company was formed for working the invention. After an expenditure of £20,000 the attempt had to be abandoned, not from any failure to obtain the spirit, but because the bread baked in the process was dry, unpalatable, and unsaleable.

When what is termed "whole wheaten flour"—that is, the entire substance of the grain, excepting only the outer bran—is baked, it is known that the resulting loaf is of a dark brown colour, sweetish in taste, and liable to be somewhat heavy and sodden. The brown colour was at one time supposed to be due to the presence of bran particles in the flour, and in 1846 an American, Mr Bentz, invented a process for removing the outer cuticle of wheat before grinding, it being supposed that the flour so prepared would yield a loaf of white colour, while utilising a larger proportion of the substance of the grain than is commonly used. To the astonishment of experimenters, however, the bread made from such flour was found to have the colour and other characteristics of whole wheaten bread. The subject was investigated by an eminent French chemist, M. Mège Mouriès, who found that the peculiar action of whole wheaten flour was due to the presence in the outer part of the seed of a peculiar nitrogenous body, to which he gave the name cerealin, and which is closely allied in composition and action to the diastase of malt. Cerealin exerts a peculiarly energetic influence on starch, transforming it into a brown adhesive mixture of dextrin and sugar. He showed that when the fermentative action of gluten

preponderates, the result is the formation of the products desired by the baker—carbonic acid and alcohol; but when the influence of cerealin prevails, lactic fermentation ensues, and dextrin, sugar, and acid substances are formed, which it is the object of the baker to avoid. Several methods of avoiding this deteriorating influence of cerealin, and at the same time securing the use of the maximum of flour, have been put in operation by M. Mège Mouriès. The process now in use at the Boulangerie Centrale de l'Assistance Publique (the Scipion) in Paris, for the preparation of the flour and baking white bread with the whole of the mill products excepting the bran, he thus describes:—"The corn is moistened with from 2 to 5 per cent. of water saturated with sea-salt, and at the end of some hours the exterior coverings only become moist and tender. The grain is then thrown between nearly closed millstones, and 70 per cent. of flour is obtained without cerealin, plus 10 to 14 per cent. of meal. This is bruised between light stones, and separated by winnowing from the greater part of the husk remnants. To prepare the bread, all the leaven is made with flour at 70 per cent., and the meal is added to the soft dough last of all; as, in spite of the small amount of cerealin which it still contains, it will not produce brown bread, because at that time the length of incubation is not sufficient to change it into a leaven. Thus white bread is produced containing all the farinaceous part of the wheat."

It not unfrequently happens that flour of good colour, and unexceptionable chemical composition, fails to yield a dough which will rise by fermentation, and the loaf from which is sweet, solid, sodden, and adhesive. Wheat that has been badly harvested, or which in any way has been allowed to sprout, has part of the gluten changed into the form of diastase, which, like cerealin, changes starch into dextrin and sugar. The gluten of flour which has been dried at a too high temperature, and of flour which has been kept in a damp situation, is modified and acts in the same manner. If dough is made with an infusion of malt, it yields a result exactly the same as that above described. It is to guard the starch of inferior flour against this deteriorative influence that a proportion of alum is used by many bakers of second-class bread. Alum has the power of preserving starch to a large extent from the metamorphic action of altered gluten, diastase, or cerealin, and of producing from an inferior flour a loaf of good texture and colour. The use of alum is regarded as an adulteration, and heavy penalties have been imposed on its detection; but its estimation in bread is a process of the greatest difficulty, and authorities are by no means agreed as to its deleterious influence. Other minerals salts have a similar protective power on the starch of inferior wheat, and lime-water has been successfully employed in place of alum. To this also it is objected by some that the addition of lime renders the valuable phosphatic salts of flour insoluble by transforming them into phosphate of lime.

Aerated Bread.—When carbonic acid, instead of being generated by fermentation within dough, is separately prepared and incorporated with flour and water, aerated bread is produced. The system by which this is effected was invented by the late Dr Dauglish, and aerated bread has been manufactured under his patent since March 1859. The system is now in operation in all the principal towns in the United Kingdom, and it appears to be steadily gaining in public favour.

The Dauglish apparatus (see fig. 3) consists of the following parts:—1st, a generator A, in which carbonic acid is evolved from chalk by sulphuric or hydrochloric acid; 2d, a gas-holder, in which the carbonic acid is stored for use after being purified in passing through water; 3d, an air-pump, for pumping carbonic acid from the gas-holder, and forcing it into the water vessel and mixer; 4th, another air-pump, for withdrawing atmospheric air from the mixer

Aerated bread.

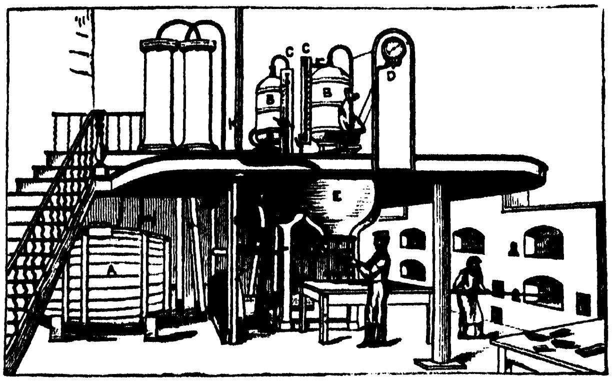

Fig. 3.—Dauglish Apparatus—double set.

before the aerated water is admitted; 5th, a water vessel B, a strong cylinder of copper capable of withstanding a pressure of 100 ℔ on the square inch, and of sufficient size to contain water for a full charge of the mixer; attached to this water vessel there are a gauge-glass C, and a pressure gauge D, for indicating the pressure of gas as it is pumped in; 6th, the mixer E, a globular vessel of cast-iron, capable of bearing high pressure, through the centre of which an axle runs, fitted with iron kneading-arms extending to the circumference of the vessel. The pumps and the revolving arms within the mixer are worked by steam power. In order to make a sack of flour into dough, a lid at the top of the mixer is opened, and the flour passed down into it through a spout from the floor above. The lid of the mixer is then fitted tightly on, and the air within it exhausted by the pump. The requisite quantity of water, about 17 gallons, is drawn into the water vessel, and carbonic acid is forced into it, till the pressure amounts to from 15 to 25 ℔ per square inch. The aerated water is then passed into the mixer, and the mixing arms are set in motion, by which, in about seven minutes, the flour and water are incorporated into a perfectly uniform paste. At the lower end of the mixer a cavity F is arranged, gauged to hold sufficient dough for a 2-℔ loaf, and by a turn of a lever that quantity is dropped into a pan ready for at once depositing in the oven. The whole of these operations can be performed in less than half an hour. When 4-℔ loaves are to be baked the lever has simply to be twice turned. At another part of the lower end of the mixer is placed a pipe G, with a stop-cock, by which dough intended to be fired as Paris bread, on the sole of the oven, is drawn off and weighed before being placed in the oven. The pressure of gas within the mixer is sufficient to force out the whole of the dough, which, immediately on being liberated, swells up by expansion of the gas confined within the tenacious mass. Currant loaves and various kinds of fancy bread are made by the aerated process by placing the necessary ingredients in the mixer along with the flour.

The advantages claimed for Dr Dauglish's process are:—

"(1.) It does away entirely with fermentation, and with all those chemical changes in the constituents of the flour which are consequent upon it.

"(2.) It avoids the loss consequent upon the decomposition of the portion of starch or glucose consumed in the process of fermentation, estimated at about from 3 to 6 per cent.

"(3.) It reduces the time requisite to prepare a batch of dough for the oven, from a period of from eight to twelve hours to less than thirty minutes.

"(4.) Its results are absolutely certain and uniform.

"(5.) It does away with the necessity for the use of alum with poor flour, and the temptation which bakers are under to use it with all.

"(6.) It has the recommendation of absolute and entire cleanliness, the human hand not touching the dough or the bread from the beginning to the end.

"(7.) The journeymen are relieved from a circumstance most destructive to their health—that of inhaling the flour dust in the process of kneading. . . .

"(8.) It will produce a healthier condition of the baking trade, and thereby diminish to a great extent the inducements which lead to the extensive system of fraud now practised upon the public by the production of adulterated and inferior bread.

"(9.) It will effect an immense saving in the material from another source, namely, by preventing the sacrifice of at least 10 per cent. in the nutritive portion of the grain, hitherto lost as human food by the method of grinding and dressing necessary in the preparation of flour for making white bread by fermentation.

"(10.) Together with the preservation of this large proportion of the entire quantity of wheat converted into flour, there is also the important result of the proportion preserved (the cerealin) being a most powerful agent in promoting the easy and healthy digestion of food."

It is objected by opponents of the Dauglish system that the product is not really bread, but only an artifical product resembling bread. It is held that the process of fermentation has a specific influence on the constitution of bread, beyond its mechanical effect of rendering the mass spongy or porous. One of the chief hindrances to the more general use of aerated bread is the fact that it is, as compared with fermented bread, insipid and tasteless. In practice, the public have not hitherto derived any advantage from the alleged economy of manufacture, and the suitability of inferior and cheap flour for the process. Although fermented bread is hurtful in some conditions, it is not easy to supplant well-made fermented loaves in general public estimation, and aerated bread can scarcely be said to have hitherto had a fair trial, as with the necessarily expensive machinery a large trade is necessary in order to return a fair profit on the capital invested.

Unfermented Bread.—Under this head is included such bread as is vesiculated by means of carbonic acid evolved from chemical substances introduced in the making of the dough. In writing the article on "Baking" for the supplement to the fifth edition of this *Encyclopædia*, published in 1816, Professor Thomas Thomson of Glasgow stated that the only end served by fermentation was the generation of carbonic acid gas, and that this might be accomplished by the use of hydrochloric acid and bicarbonate of soda. About 1842 Mr Henry Dobson commenced to manufacture bread on this system, and obtained a patent for his process. He used hydrochloric acid and bicarbonate of soda in such proportions that while, by their reaction, they liberated sufficient carbonic acid to aerate the dough, they formed chloride of sodium or common salt enough for the bread. Liebig, in his *Familiar Letters*, says regarding this system:—"Chemists, generally speaking, should never recommend the use of chemicals for culinary preparations, for chemicals are seldom met with in commerce in a state of purity. Thus, for example, the muriatic [hydrochloric] acid which it has been proposed to mix with carbonate of soda in bread is always very impure, and very often contains arsenic." The sesquicarbonate of ammonia is also used as a source of carbonic acid in vesiculating bread, and it, on account of its highly volatile nature, is entirely driven off in the process of baking. A great amount of private or domestic baking is conducted on the same principle, butter milk and bicarbonate of soda being used for mixing the dough in making "scones." In this case the lactic acid of the milk combines with the soda, liberating carbonic acid. The baking powders and yeast powders which are sold, and the so-called self-raising flour, all depend for their action on the mixture of bicarbonate of soda with some organic acid, such as tartaric or citric acid.

Baking Machinery and Ovens.—The art of baking, although it is the most important of all industries connected with the preparation of human food, is one which is still carried on in the most rude and primitive manner. While modern inventions and the progress of improvement have changed the conditions under which nearly all arts and manufactures are conducted, the baking of bread is still conducted as it was during the palmy days of ancient Greece. The nature of the processes necessary for the preparation of bread, the limited time it will keep, and the consequent impossibility of storing the product or sending it any considerable distance, tend to keep the trade in the position of a limited and local handicraft. It is, therefore, not a pursuit which attracts capitalists, and master bakers are mostly in the position of small tradesmen, without either the inclination or ability to invest money in expensive machinery and fittings. In the case of biscuit-baking the conditions are quite different, and it, as has been seen, has developed into a great manufacture, with elaborate and complex machinery and the most perfect mechanical appliances. Many forms of machine have been proposed as substitutes for the rude and laborious manual labour—always unfavourable to health, and sometimes not very cleanly—involved in baking. Many of these machines admittedly produce better bread than can be made by handwork, and that at no inconsiderable saving of material and time, but the necessity of either steam or water power for their effective working greatly restricts their use.

Mach

The two processes to which machinery has been successfully adapted, are the mixing of the sponge and the kneading of the dough. Attempts have been made to mould loaves by machinery, but these have hitherto failed; nor has the endeavour to fire bread in travelling ovens yet been practically successful. A great variety of kneading machines have been suggested and used, since the first trial of such an implement in Paris upwards of a century ago. The various plans upon which such machines have been constructed will be seen in the accompanying illustrations. Fig. 4 is a form of dough-making machine in common use. It consists of a trough or box, the lower portion of which is semi-cylindrical, hung on a spindle, with a series of iron crossbars revolving inside. It is made to be worked by either hand or steam-power, and of various sizes, as required by bakers. In this machine the whole of the operations connected with setting the sponge, breaking the sponge, and mixing the dough, are performed. The gearing is arranged to give a fast motion for setting the sponge, and a slow motion towards the close of the dough making, when it is desirable to draw out the mass in order to give it a "skin," or smooth superficial texture. A worm-wheel, working in toothed gearing, tilts over the machine when the process of kneading is complete, and the dough is then conveyed to the scaling and moulding table.

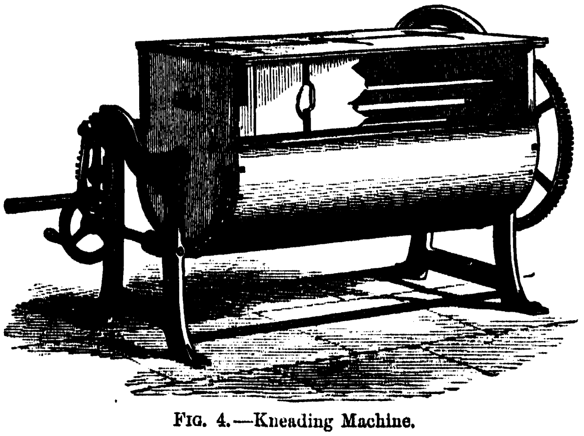

FIG. 4.—Kneading Machine.

Fig. 5 represents a kneading-machine, of a highly approved form, used in the great Scipion bakery of Paris, the inven-

Fig. 5.—Boland's Kneading-Machine.

tion of M. Boland. Externally it is like the former, and it is also geared to move at two rates of rapidity. It has further an adjustment by which the force of the motion is increased while its rate is diminished. The main peculiarity of M. Boland's *pétrin méchanique* consists in the form of the revolving blades inside the trough. These blades are so arranged that they operate when in motion some-

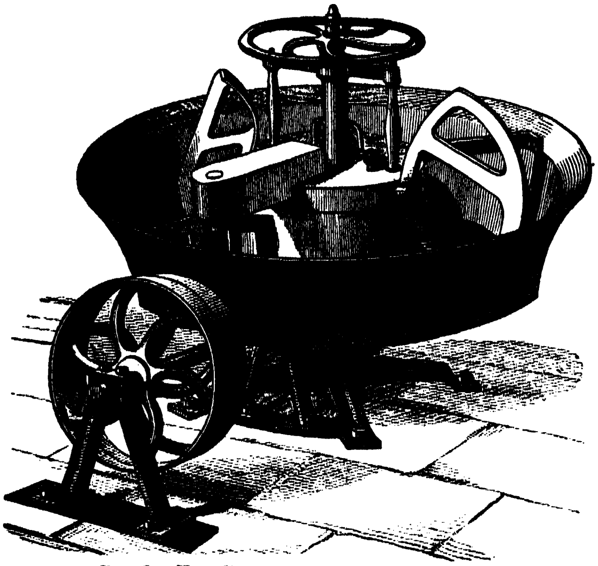

Fig. 6.—Kneading-Machine of Deliry-Desboves.

what like alternate screws, and so toss backward and forward the dough when it is thin, and lift and draw it out when stiff, passing it to each side of the trough alternately. An entirely different form of kneader is seen in fig. 6. This also is of French origin, the invention of M. Deliry-Desboves of Soissons (Aisne). Its construction and operation are thus described :—"The trough is a cast-iron basin, which turns on a vertical axis. The interior is provided with a kneader, shaped like a lyre, which first works up the dough and then divides it during the entire period of operation. Two other implements are also used, of a helical form, to draw out and inflate the dough in all directions, part by part, as is practised in kneading by hand. . . . The baker in charge can regulate the paste without stopping the mechanism. The water and leaven are first introduced, the trough is then set to work, the 'workers' employed to manipulate the dough are put in gear, and the leaven being diluted and flour added, the kneaders are also put in gear. After the lapse of twelve or fifteen minutes the dough is sufficiently kneaded, and, by turning the hand wheel fixed to the screw on the vertical shaft, the three kneaders are thrown out of gear. The implement which effects the cleaning of the trough is then removed, and its place supplied by a balance-hook, by which the dough may be weighed in the trough itself. It is simply necessary to turn the basin on its axis as required, until the whole of the dough is weighed."—(Villain, *Etudes sur l'Exposition de* 1867.)

The fourth form of mechanical kneader we shall describe is that invented by Messrs Vicars of Liverpool, who are extensive makers of all forms of machinery connected with bread and biscuit making. This machine (fig. 7) consists

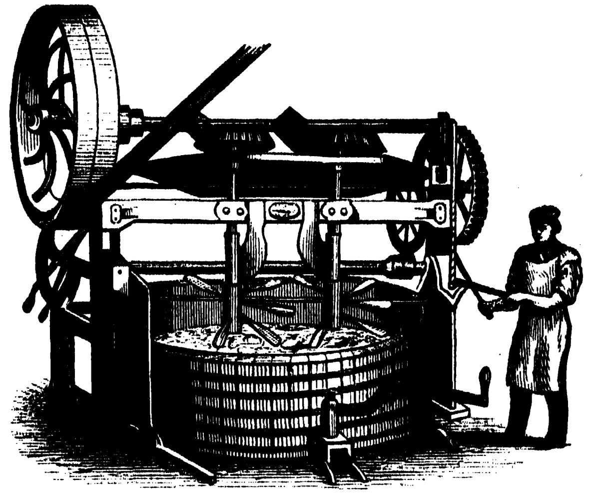

Fig. 7.—Patent Vertical Mixer.

of two vertical shafts, carrying radial arms. These arms pass each other in opposite directions, so that, in addition to a tearing action on the dough, which the knives have on passing each other, they have a screw action, pressing the dough down on one side and up on the other. The vessels containing the dough are made of wood, of an oval form, to correspond with the action of the machine. One considerable advantage connected with Messrs Vicars's machine is, that any number of troughs can be worked by the same pair of mixing shafts, as the troughs are movable, and are raised to, or lowered from, the blades of the mixer by means of friction wheels and spur gear. A baker can thus have several troughs containing sponges in different stages of advancement, all mixed by one pair of shafts, and all in their turn being made into dough by the same shafts.

Much thought and skill have been expended in the endeavour to effect improvements in the ordinary form of a baker's oven, but hitherto no plan has been devised which produces bread of a quality superior to that fired in the oven which is commonly used. A baker's oven of the common description is a low vaulted chamber, about 10 feet long, by 8 feet wide, and 30 inches high. It is built and floored of stone or brick, and has a small door in front by which the moulded dough is put in and the loaves withdrawn. At one side of this door, in the extreme corner, are placed the furnace and fire-grate, opening into the oven, and at the opposite corner, the smoke flue by which smoke escapes from the interior. The heat is by this arrangement carried throughout the entire oven, and when the temperature is sufficient the fire is withdrawn, the flue shut, and the dough is quickly introduced on a "peel," or long wooden shovel. Various efforts have been made to effect the heating of ovens by fire external to the chamber itself, but they fail to produce that radiation of heat which is found essential to good baking. Perkin's hot-water oven for some time met with favour in Great Britain, and a modification of it was employed in France, Ovens.

On this system the oven is heated by superheated water, conveyed from a stove through closed pipes, which are coiled round the entire interior of the oven. This oven has the recommendation of perfect cleanness, and the temperature in it is easily regulated; but it is costly in construction, and the method has not commended itself in practice. Among ovens heated from the exterior, that of M. Rolland takes a high place for ingenuity and novelty of construction. Its characteristic peculiarity consists in the possession of a revolving sole, which not only allows the easy introduction and withdrawal of the bread, but the bringing of the different parts regularly and uniformly under the influence of the heat applied. The revolution of the sole is accomplished by a handle worked from the front of the oven; and besides this rotatory motion the sole can also be raised or lowered so as to bring either the upper or under side of the bread close to the heat as desired. The heating of M. Rolland's oven is effected by means of flues, which pass radially under and over the revolving sole. The chief objection urged against this form of oven is, that the air within it becomes too dry, which detracts from the flavour of the loaves fired in it. The use of the Vienna oven is general in Germany, and is extending in Paris for the baking of small or Vienna bread. It is egg-shaped in form, with an inclined sole, a very small aperture, and a low roof.[1] Its average internal dimensions are 12 feet in depth, 10 feet wide, and 18 inches high. In the best of these ovens glazed tiles are used for the sole. The inclination of the sole facilitates the filling and emptying of the oven; and the confined space of the interior retains a large proportion of moisture, which gives a fine colour to the crust and flavour to the crumb of the bread.

Qualities of Bread.—The process of baking changes the structure of the crust or outer part of a loaf, and, according to Reichenbach, develops in it a substance termed *assamar*, which he says has an influence in retarding the waste of tissue. It does not alter the starch of the crumb or internal part, but only swells the granules, and by the induced sponginess of the mass renders it readily digestible. Well-baked bread should have a yellowish-brown crust; the crumb should be uniform in texture, permeated with minute cavities, and without "eyes" or large air-cells. The colour of the crumb, unless in the case of whole wheaten bread, should be white; it should be free from acidity and sourness. It should keep sweet and eatable for several days; and when stale it will be found to become soft and pleasant by again heating it in an oven, after which, however, it rapidly changes. According to Dr Frankland's determinations, "1 ℔ of the crumb of bread, if digested and oxidised in the body, will produce an amount of force equal to 1333 tons raised 1 foot high. The maximum of work which it will enable a man to perform is 267 tons raised 1 foot high. 1 ℔ of crumb of bread can produce, at the maximum, $1\frac{7}{10}$ oz. of dry muscle or flesh."

The adulteration of bread, and its detection, are treated under the heading ADULTERATION, vol. i. p. 170. (J. PA.)

BAKU, or BADKU, the chief town of the government of the same name, in the Russian province of Transcaucasia (Daghestan), situated in the peninsula of Apsheron, on the west coast of the Caspian, and possessing one of the most spacious and convenient ports in that sea. Long. 49° 53′ E., lat. 40° 23′ N. It is built in the form of an obtuse triangle, on the slope of an arid hill, and is defended by a double wall and ditch constructed during the reign of Peter the Great. The general appearance of the town is decidedly Oriental, with its flat-roofed houses rising one behind the other, often in so close proximity that the top of the one forms the courtyard of the next. The hill is crowned by a castle, which dates from the 15th century, and the mosque of Shah-Abbas, still in good preservation. At the entrance of the harbour stands the Maiden's Tower, now used as a lighthouse, which derives its name from a tragedy like that of the Cenci. Baku is not only a principal station of the Russian fleet, but it carries on a very extensive trade, exporting naphtha, iron, linen, and woollen goods, and receiving in return cotton, grain, fruits, &c. The numerous naphtha wells in the neighbourhood, and the remarkable escape of inflammable gases, rendered Baku a favourite resort of the fire-worshippers, who for long maintained their temples in the district; but, though the natural phenomena display themselves as abundantly as ever, they are now almost entirely deserted by devotees. The Arabian Masudi, in the 10th century, is supposed to be the first to mention "Baki" and its fire-breathing mountain; and the naphtha wells are probably those alluded to by Marco Polo. In 1509 it was taken by the Persians, who lost it to the Turks, but recovered it under Shah-Abbas. Captured by the Russians in 1723, it was restored to Persia in 1735, but after various vicissitudes it was finally incorporated with the Russian empire in 1806. (See Goldschmid's *Telegraph and Travel*, 1874; Filippi's *Viaggio in Persia*, 1865; *Hist. des découvertes faites par div. sav. voyageurs*, Lausanne, 1784; *La Tour du Monde*, 1863; "Baku" in *Zeitschrift der Deutsch. Geol. Gesellsch.*, 1874.)

BALA, a market-town of Wales, county of Merioneth, and hundred of Penllyn, at the northern extremity of the lake of the same name, 17 miles N.E. of Dolgelly. It consists principally of one wide street. Its manufactures are flannels, stockings, gloves, and other woollen hosiery. There is an endowed grammar school, founded in 1712, and a theological college, belonging to the Calvinistic Methodists. The Rev. Thomas Charles, well known in connection with the religious literature of his country, was long a minister at Bala. Population, 1539. The Lake of Bala, which is 4 miles long and about half a mile broad, is subject to sudden and sometimes dangerous floods. It is very deep and clear, and abounds with pike, perch, trout, eels, and the *gwyniad*, or *Coregonus fera*.

BALAAM, or rather BILEAM, the son of Beor, belonging to Pethor, by the river Euphrates in Aram, is represented in Scripture as a seer who possessed the power of blessing and cursing effectually. According to the narrative in Numbers xxii.–xxiv., he was invited by Balak, king of Moab, to come and curse Israel, in order to ensure the latter's defeat. Jehovah, however, forbade him to go as he was requested, and therefore he refused to accompany the deputation of elders, who had been sent to invite him, "with the rewards of divination in their hand." After the arrival of a second embassy more imposing than the first, he received divine permission to go, but only on condition that he should adhere strictly to what Jehovah should tell him. He set out accordingly, and in his journey experienced the anger of the Lord, an angel being sent to stop his progress, who was perceived only by the ass on which the prophet was riding. After Balaam's eyes had been opened he saw the angel, and declared his willingness to go back, but received permission to continue his journey on condition of saying nothing but what was suggested to him by God. His reception by Balak was honourable and imposing, yet he continued faithful to Jehovah, and told the king he would only announce what Jehovah revealed. Standing on the height of Baal-Bamoth, and surveying the tents of Israel, he declared his inability to curse a people so peculiar and righteous. Brought next to the top of Pisgah, and beholding thence a part of the Israelite camp, he announced that Jehovah saw no iniquity or perverseness in Jacob; that He was with them; that they were therefore strong and

[1] The Vienna oven is figured in Knapp's *Technology*, vol. iii. p. 192.

victorious. Conducted afterwards to the top of Peor, he surveyed the army of Israel, and predicted their future, their goodly dwellings in Canaan, and their successful wars against the nations down to Saul's time. Though Balak was angry and interrupted him, Balaam continued his prophecy, announcing Israel's valiant deeds, from David down to Hezekiah. Upon this he returned to his home.

Another account of Balaam appears in Numbers xxxi. 8–16, Joshua xiii. 22, where we learn that he advised the Midianite women to seduce the Israelites to the licentious worship of Baal, and that he was slain in a war with the Midianites.

The character given to Balaam in the first account is a favourable one. He is a worshipper of Jehovah the true God, receives divine revelations, and repeatedly declares that he will not go beyond or against them. Faithful to his calling, he steadfastly resists temptations sufficiently powerful, and therefore God communicates His Spirit to him, enabling him to predict the future of Israel.

The second account is unfavourable. In it he appears as a diviner, קֹסֵם, a heathen seer, who tempted the worshippers of the true God to idolatry. Instead of being a prophet of Jehovah, receiving visions and revelations, a man to whom the Almighty came by night, giving him instructions what to do, he is an immoral soothsayer. Of the two accounts, the latter, brief as it is, seems entitled to greater consideration. The former is elaborate and artificial, the theme being the glorification of the chosen people by the mouth of one of their enemies. An inspired seer from the far distant land of Aram is called in to bless the Israelites. He does so reluctantly, but like a true prophet, announcing nothing but what came to pass. The way in which he is taught the high destiny of the chosen people is instructive. Ignorant at first of Israel's relation to the true God, and thinking they were like others, he was disposed to curse them, but is enlightened, and forcibly impelled to follow the divine revelations. From a heathen *mantis* he is converted into a true prophet by revelations and visions which he cannot resist. The seer is taken to three places in succession, whence he surveys Israel, and utters oracular sayings concerning them. Three times the angel of the Lord stands in the way, and three times the ass is smitten by Balaam. There are four prophetic announcements—xxiii. 7–10, 18–24; xxiv. 3–9, 15–24. The first refers to the separate condition of Israel, their numbers, and their worship of the true God amid the idolatry of the surrounding nations. The second declares that God blesses Israel because there is no iniquity or perverseness in them, that He dwells among them, reveals himself to them, and makes them powerful and victorious. Both these refer to Mosaic times, or at least to times not later than Joshua. But the third announcement has the character of prediction, and refers to future events. Hence Balaam is introduced as a man whose eyes are opened, who hears the words of God, and sees visions of the Almighty. The condition of the people down to the time of Saul is glanced at, their secure settlement in Canaan, and victorious wars with the native races. The fourth prophecy apparently carries down the history to the time of Hezekiah; and a future ruler is distinguished as the star out of Jacob, the sceptre out of Israel, the conqueror of the Moabites and Edomites. The mention of the Kenites and Assyria in ver. 22, the former of whom were allies of Edom, shows, in the opinion of some recent critics, that the writer was acquainted with the Edomite wars under Amaziah and Uzziah, and hoped that the latter power would permanently subjugate the restless Edomites. This would bring the composition down to the first half of the 8th century. Verses 23 and 24 are obscure, but probably refer to no event later than Hezekiah. A fleet from the Phœnician Cyprians seems to have attacked the Canaanitish and Phœnician coasts, threatening the Syrians farther north.

The writer of Num. xxxi. 8, 16, Joshua xiii. 22, is the Elohist, whose account is very brief. Meagre, however, as it is, it is probably historical. A heathen soothsayer, connected with the Midianites, perished in one of their battles with Israel. The writer of Numbers xxii.–xxiv. is, in this view, the Jehovist, who, under the name of Balaam, gives expression to his ideas and hopes in the elevated diction of an inspired prophet. As Jacob and Moses had pronounced blessings on Israel under the immediate inspiration of the Almighty, so Balaam is summoned from a distant land to eulogise the same people.

The character of Balaam has been apprehended very variously. Such diversity must exist according as the Elohist or Jehovist is followed. The Old Testament writers who mentioned him afterwards were influenced by the Jehovistic notice, and pronounce no judgment upon the seer (Deut. xxiii. 5, 6; Joshua xxiv. 9, 10; Micah vi. 5; Nehemiah xiii. 2); but the New Testament authors followed the Elohistic account, and speak of him disparagingly, attributing to him love of "the wages of unrighteousness," madness, idolatrousness, and impiety (2 Peter ii. 15, 16; Jude 11; Rev. ii. 14). Josephus calls him μάντις ἄριστος τῶν τότε, "the best prophet of his time," supposing him to be a prophet of the true God, but with a disposition ill-adapted to resist temptation. Philo describes his character more critically: "There was a man at that time celebrated for divination, who lived in Mesopotamia, and was an adept in all the forms of the divining art; but in no branch was he more admired than in augury; to many persons, and on many occasions, he gave great and astounding proofs of his skill. For to some he foretold storms in the height of summer; to others drought and heat in the depth of winter; to some scarcity succeeding a fruitful year, and then again abundance after scarcity; to others the overflowing and drying up of rivers, and the remedies of pestilential diseases, and a vast multitude of other things, each of which he acquired great fame for predicting." The unfavourable character drawn of him by Philo is that which is generally taken by the later Jews. The later Targumists call him a sinner and an accursed man, while the Talmudists make him the representative of the godless, in contrast with Abraham, the representative of the pious. Yet they do not ignore his prophetic gift. The Midrashim about him are hardly worth mentioning, such as that he was one of Pharaoh's counsellors, that he was governor of a city in Ethiopia which he excited to rebellion, but was unable to defend against Moses at the head of an army who stormed the place and put Balaam to flight. In Yalkut (§ Shemoth) he is said to have been identified by some with Laban, Jacob's father-in-law; by others with Elihu, Job's friend; while others say that Jannes and Jambres were his sons. In Sanhedrin (§ Chelek) he is said to have been blind of an eye. These, and other rabbinical fables, are entirely worthless; and Origen's belief that the Magi from Persia, who came to worship the infant King of the Jews, learnt the meaning of the star from Balaam's prophecies, is of the same character.[1]

Most of the Fathers, including Augustine and Ambrose, judged him to be a soothsayer or magician, a prophet inspired by the devil. A few, as Tertullian and Jerome, took a more favourable view of his character. The Mahometans have various fables concerning Balaam. They say that he was of the race of Anakim, or giants of Palestine, and that he read the books of Abraham, where he got the name Jehovah, by virtue of which he predicted the

[1] See Fabricius's *Codex Pseudepigraphus Vet. Test.*, p. 807, &c.

future, and got from God whatever he asked. This procured him great renown. In consequence, however, of his prevarication, God was offended with him, and left him to himself, so that he fell into infidelity. It is generally supposed that the words in the Koran (§ Al-Araf) refer to him:—"The history of him unto whom we brought our signs and he departed from them; wherefore Satan followed him, and he became one of those who were seduced. And if we had pleased, we had surely raised him thereby unto wisdom; but he inclined unto the earth, and followed his own desire. Wherefore his likeness is as the likeness of a dog, which, if thou drive him away, putteth forth his tongue; or if thou let him alone, putteth forth his tongue also."

It has been conjectured with much probability that the Arabic wise man, commonly called Lokman, is identical with Balaam. The two names coincide in meaning, *devourer*, *swallower*;[1] and the names of their fathers are also alike. The Jews suppose Balaam to have been a Nahorite, and so Lokman is regarded by many Arabic authors, though the more general opinion is that he was an Abyssinian slave who lived in the time of David, and was renowned as a Hakim. The proverbs or fables attributed to him are of Greek origin.

Modern critics are divided in opinion respecting him. Three leading views embrace the varieties of belief as to his true position, viz., that he was an idolater and soothsayer, whose soul was uninfluenced by true religion—a sorcerer who had acquired reputation by his insight into the force of nature and his incantations; that he was a true prophet of God, a pious man who fell through covetousness; and that he was a heathen soothsayer and a prophet of Jehovah at the same time, occupying an intermediate position, with an incipient knowledge and fear of God, needing but to be developed, though checked by the love of gain. It appears impossible to arrive at a definite or comprehensive view of one who is described in different sources inconsistently. Bishop Butler, not recognising that the history of Balaam has poetical elements, and that different traditions are given respecting him, considers him a very wicked man under a deep sense of God and religion, persisting still in his wickedness, and preferring the wages of unrighteousness even when he had before him a lively view of death. His mind was distracted by contradictory principles of action. All we know about him amounts to very little. After admitting that a heathen soothsayer of this name existed in Mesopotamia, and had acquired some renown in the regions adjoining, and that he was employed in some way as a medium for uttering eulogiums upon Israel, of whose pre-eminence and permanence he is fully conscious, nothing else can be affirmed with certainty. (Davidson's *Introduction to the Old Testament*, vol. i. p. 328, &c.; Ewald's *Geschichte des Volkes Israel*, zweyter Band, p. 298, &c., 3d edition, and his *Jahrbücher*, part 8, p. 1, &c.; Kurtz's *Geschichte des alten Bundes*, zweyter Band, p. 454, &c.; Hengstenberg's *Die Geschichte Bileam's und seine Weissagungen*, 1842; Winer's *Realwörterbuch*, *s.v.* "Bileam;" Knobel's *Die Bücher Numeri, Deuteronomium, und Josua erklärt*, p. 121, &c.; Schenkel's *Bibel-Lexicon*, *s.v.* "Bileam;" and Hamburger's *Real-Encyclopædie fur Bibel und Talmud*, *s.v.* "Bileam.")

BÁLÁGHÁT, a British district in the Central Provinces of India, situated between 21° and 23° N. lat. and 80° and 81° E. long.; bounded on the N. by the district of Mandlá; on the E. by the district of Chhattisgarh; on the S. by Chhattisgarh and Bhandárá; and on the W. by the district of Seoní. Bálághát forms the eastern portion of the central plateau which divides the province from east to west. These highlands, formerly known as the Ráigarh Bichhiá tract, remained desolate and neglected until 1866, when the district of Bálághát was formed, and the country opened to the industrious and enterprising peasantry of the Waingangá valley. Geographically the district is divided into three distinct parts:—(1.) The southern lowlands, a slightly undulating plain, comparatively well cultivated, and drained by the Waingangá, Bágh, Deo, Ghisrí, and Son rivers. (2.) The long narrow valley, known as the Mau Táluká, lying between the hills and the Waingangá river, and comprising a long, narrow, irregular-shaped lowland tract, intersected by hill ranges and peaks covered with dense jungle, and running generally from north to south. (3.) The lofty plateau, in which is situated the Ráigárh Bichhiá tract, comprising irregular ranges of hills, broken into numerous valleys, and generally running from east to west. The highest points in the hills of the district are as follows:—Peaks above Lánjí, 2300 or 2500 feet; Tepágarh hill, about 2600 feet; and Bhainsághát range, about 3000 feet above the sea. The principal rivers in the district are the Waingangá, and its tributaries, the Bágh, Nahrá, and Uskál; a few smaller streams, such as the Masmár, the Máhkárá, &c.; and the Banjár, Hálon, and Jamuniá, tributaries of the Narbadá, which drain a portion of the upper plateau. Bálághát contains very extensive forests, but they do not produce timber of any great value. They teem with wild animals, from the great bison to the fox; 470 beasts and venomous snakes were killed in 1867–68, a total reward of £156 being paid under this head. The district contained in 1868 an assessed area of 1462·08 square miles or 935,731 acres, of which 214,587 acres were under cultivation; 488,510 grazing lands; 11[illegible]38 culturable, but not actually under cultivation; 115,[illegible]96 unculturable waste. The census report of 1872 returned the area at 2608 square miles. The census of 1866 showed a population of 170,964. This had in 1872 increased to 195,008, residing in 37,192 houses and 781 villages; average number of persons per square mile, 74·77; per village, 249·69; per house, 5·24. Of the total population, 131,176 or 67·27 per cent. were Hindus; 2934 or 1·50 per cent. Mahometans; 39 Buddhists; 11 Christians; 60,848 or 31·20 per cent. of unspecified religions of aboriginal or imperfectly Hinduised types.

Since 1867 considerable encouragement has been given to the cultivating tribes of Ponwárs, Kunbís, Marárs, &c., of the low country to immigrate, and take up lands in the upland tracts. By this means a large quantity of jungle lands has lately come under cultivation. The acreage under the principal crops grown in the district is returned as follows:—rice, 188,312 acres; wheat, 585; other food grains, 8770; oil-seeds, 3436; sugar, 505; fibres, 100; tobacco, 638; total, 202,346 acres. Iron is smelted by the Gonds; gold exists in the beds of some of the rivers, but not in sufficient quantities to repay the labour of washing. There are no regularly made roads in the district. Five passes lead from the low country to the highlands, viz., the Bánpur Ghát, the Warai Ghát, the Pancherá Ghát, the Bhondwá Ghát, and the Ahmadpur Ghát. For revenue purposes the district is divided into two subdivisions, the Búrhá Tahsíl and the Paraswárá Tahsíl. In 1868–69 the total revenue of the Bálághát district amounted to £11,746, of which £6754, or 57 per cent., was from land. For the protection of person and property, Government maintained, in 1868, 115 policemen, at a total cost of £1156, 16s. In 1868 only two towns in the dis-

[1] בִּלְעָם from בָּלַע, with the formative letter ם. It has been derived from בלע—עם (Sanhed. 105), *destroyer* or *corrupter of the people*, so that the name has passed for a typical designation of Israel's enemy; and this is reflected in the Greek word Νικολαίτης (Rev. ii. 6), from *νικᾶν* and λαός, as if the Nicolaitanes were essentially Balaamites, or seducers. But this etymology of the name Balaam is improbable.

trict had upwards of 2000 inhabitants, viz., Hattá, population, 2608, and Lanjí, population, 2116. About 60 years ago the upper part of the district was an impenetrable waste. About that time one Lachhman Náik established the first villages on the Paraswárá plateau, on which there are about 30 flourishing settlements. But a handsome Buddhist temple of cut stone, belonging to some remote period, is suggestive of a civilization which had disappeared before historic times.
